THE Antrim 1-5-

GARDENER'S DICTIONARY:

Containing the METHODS of
CULTIVATING *and* IMPROVING
THE
Kitchen, Fruit, *and* Flower Garden,
AS ALSO, THE
Phyſick Garden, Wilderneſs, Conſervatory,
AND
VINEYARD;
According to the PRACTICE of the
Moſt *Experienced Gardeners* of the *Preſent Age.*

Interſperſed with
The Hiſtory of the PLANTS, the Characters of each GENUS,
and the Names of all the particular SPECIES, in *Latin* and *Engliſh*; and an
Explanation of all the TERMS uſed in BOTANY and GARDENING.

Together with
Accounts of the Nature and Uſe of *Barometers*, *Thermometers*, and *Hygrometers*,
proper for GARDENERS; And of the Origin, Cauſes, and Nature of METEORS, and the
particular Influences of *Air*, *Earth*, *Fire*, and *Water*, upon *Vegetation*, according to the beſt
NATURAL PHILOSOPHERS.

Adorn'd with COPPER PLATES.

By *PHILIP MILLER*, Gardener to the Worſhipful Company of APOTHECARIES,
at their *Botanick Garden* at *Chelſea*, and F. R. S.

——*Digna manet divini gloria ruris.* VIRG. GEO.

The FIFTH EDITION, Corrected.

DUBLIN:
Printed by S. POWELL,
For R. GUNNE, in *Capel-ſtreet*; G. RISK, G. EWING, and W. SMITH, in *Dame-ſtreet*;
and J. SMITH, on the *Blind-key*; Bookſellers.

TO

Sir *HANS SLOA*

PRESIDE

AND, TO THE

COUNCIL *and* FELLOWS

OF THE

ROYAL SOCIETY of *LONDON*,

FOR

Improving Natural Knowledge;

THIS

GARDENER's DICTIONARY

Is Humbly DEDICATED;

By Their moſt Obedient Servant,

Philip Miller.

RTISEMENT,

CONCERNING THIS

dition of the *Gardener's Dictionary.*

is a very uncommon Thing for Books of ſuch Bulk as this to go through ſo many Editions in ſo ſhort a Time. This is the fifth Edition within leſs than Ten Years; which is an undoubted Evidence of its great Excellency and Uſefulneſs above any other Book of the Kind.

Since the laſt Dublin *Edition of this Work, which was ſo well received by the Public, that the whole Impreſſion was bought up in a very ſhort Time, the Author has publiſh'd a new Edition of the Firſt Volume, to which he has added a Second Volume, containing ſuch Things as had been omitted in the Firſt, together with ſuch Alterations and Amendments, as, upon a Review of the Whole, the Author thought proper to make, ſome Account of which is to be found in his Prefaces.*

The Editors of the former Dublin *Edition have been ſolicited to give a new Edition of this Work; and, in order to make it as uſeful as poſſible, have been prevailed with to range the two Alphabets in the two Volumes of the* London *Edition under one Alphabet; which they have done with great Care.*

Beſides this obvious Advantage, of not being obliged to have recourſe to more Volumes, or more Alphabets, than one, for any Thing that is ſought for in ſuch a Work as this, the preſent Edition has ſome other conſiderable Advantages above the London *one, as,*

I. *The Author having intended the Second Volume as a Supplement to the Firſt, was obliged in many Places, to make Uſe of Repetitions of what he had ſaid, under the ſame Heads, in the Firſt Volume, which add conſiderably to the Bulk and Expence of the Book. As theſe can be of no manner of Uſe, and would rather create Confuſion in the Work, as it is now diſpoſed, they have been intirely omitted.*

II. *Many Errors have been corrected, and thoſe not merely typographical, but ſuch as made many Paſſages quite unintelligible, particularly in Quotations from other Authors, where ſometimes whole Lines, and intire Sentences, have, by the Careleſſneſs of thoſe who had the Direction of the Preſs, been left out; and in the mathematical Parts, where the utmoſt Care is neceſſary, many groſs Errors have crept in. All theſe have been carefully corrected from the Authors referred to in thoſe Places. And,*

III. *That this uſeful Book may get into the greater Number of Hands, the Editors have publiſh'd it in ſuch a Form as might make it cheap to the Buyer, at the ſame Time that they have conſulted Neatneſs and Elegancy.*

For the Benefit of thoſe who cannot go to the Expence of buying the large Work, the Editors have publiſh'd The GARDENER'S KALENDAR, *directing what Works are neceſſary to be done every Month in the Kitchen, Fruit, and Pleaſure Gardens,* &c. *by the ſame Author; which is ſold for one* Engliſh *Shilling.*

BRITISH MUSEUM 15 OCT 67

THE AUTHOR's PREFACE TO THE THIRD *English* EDITION.

AS the two former Editions of this Work have been ſo generally well receiv'd, not only in *England*, but alſo in ſeveral other Parts of *Europe*: I thought there was no better Way of making my Acknowledgments to the Publick, for their kind Reception of my poor Performance; than by devoting all my leiſure Hours, to improve it as much as I was able, agreeably to what I had promiſed in the Preface to the firſt Edition.

ACCORDINGLY I minuted down all my Obſervations from time to time, as they occurred to me; and alſo noted whatever any of my Friends (who had been ſo good as to remark ſuch Things as had been omitted in the former Editions) had obſerved to me.

THESE I propoſed to inſert in this Edition; but while I was drawing of them up, it was obſerved to me, by many of my Friends, that there were a great Number of Plants, in ſeveral curious Gardens in *England*, which were not to be found mentioned in the *Gardener's Dictionary*; which being the moſt generally uſed Book of the kind, they judged to be a great Fault. Some of theſe Plants were deſignedly omitted in the firſt Edition of the Work, as I was at that Time in ſome Doubt of the Succeſs of the Book, had I ſwell'd it to too great a Bulk, eſpecially as there had been ſo many Pieces of Gardening publiſhed, that the Publick might be eaſily ſuppoſed to be tired of reading any more on that Subject. Others, indeed, were accidentally ſlipped over by Miſtake.

But beſides theſe, a great Number of new Plants have been brought into *England*, from many different Parts of the World, within a few Years paſt; eſpecially from *America*, many of which are ſo very different in their outward Structure, that they afford an agreeable Pleaſure, even to ſuch Perſons who only conſider them as Varieties, without examining their Parts more diſtinctly. But to the Curious in Botany they are much more ſurprizing, ſince many of them are ſo different in their Characters, as not to be ranged under the many Genus's which had been conſtituted by the ſeveral Writers in Botany.

This has occaſioned the many new Names of Plants, which are not to be found in any of the former Books of Botany. Some of theſe new-diſcovered Plants retain the Names by which they were known amongſt the Natives of *America*: but the greateſt Part of them have been named after the moſt eminent Botaniſts in *Europe*. But as theſe Names of the Plants are ſcattered in ſeveral Books of Botany, and many of them, which were lately diſcovered, not yet publiſhed; ſo it was recommended to me, by ſome Gentlemen, to whoſe Judgment I ſhall always pay a great Regard, to add them in this Edition of the *Gardener's Dictionary*.

This I immediately undertook, and had made a conſiderable Progreſs in it before the Book went to the Preſs; but finding the Number of Plants increaſe upon me very much, and that the adding of their Culture would ſwell the Book greatly beyond the former Size, I choſe rather to deſiſt from adding new Matter, and thought it beſt to reprint it with Corrections only, and reſerve the reſt to be publiſhed in a ſeparate Volume; which muſt alſo be much more agreeable to the Purchaſers of the former Editions, for whom I ſhall always have ſo juſt a Regard, (agreeable to my former Promiſe, and my conſtant Intentions) as not to do any thing which may render their Books imperfect.

For which Reaſon, where-ever there are any Corrections of Moment in this Edition, they ſhall be inſerted in the Second Volume, for the ſake of perfecting the former Impreſſions.

The moſt material Difference between the preſent Edition and the former ones, is in the *Kalendar*, which is here printed as it was inlarged in the *Octavo* Edition; but it may be preſumed, that the far greater Number of the Purchaſers of the *Dictionary*, have alſo bought the *Kalendar*, ſo there are few of thoſe Perſons who will conſult the *Folio* for ſuch Things as are comprized in the *Kalendar*, where they are much eaſier to be turned to, than where the ſeveral Months are diſtributed according to the Alphabetical Order obſerved in the *Dictionary*.

As the *Art of Gardening* is univerſally acknowledg'd to be one of the moſt delightful and uſeful Amuſements that can entertain the Mind of Man, I think it needleſs in this place to expatiate in its Praiſe; I ſhall therefore only beg leave to tranſcribe a few Things from the Preface to the former Editions, which are more immediately applicable to the preſent Work.

In the firſt place, I muſt repeat my Acknowledgments to the Learned Dr. *Hales* of *Teddington*, to whoſe large Diſcoveries in the vegetable Kingdom (whereby many miſtaken Notions concerning the Motion of the *Sap* in Plants, *&c.* are ſet in a clear Light) I am greatly indebted for many valuable Things in this Performance.

I must alſo obſerve, that where I have borrowed any thing from the Works of the moſt reputed Philoſophers of the preſent Age, I have generally acknowledged whence I had it. But this has been principally with regard to the Theory relating to Meteors, *&c.* on which Heads, it would have been a Preſumption to offer any thing of my own. For in the Directions laid down for the Management of all the various Plants herein-mentioned, there is little ſaid but from my own Experience, or from that of ſome other particular Friends. And here I can ſay, what few, who have written before me on this Subject, could do, *viz.* That there are very few Plants (out of the great Number herein mentioned) which I have not cultivated; and the Inſtructions given for their Propagation, *&c.* are ſuch as have ſucceeded beſt with me.

As to the Method purſued in the following Work, it is proper to repeat, that I choſe rather to range the Plants under their proper *Latin* Names, which are better aſcertained than the *Engliſh*, and more generally known: But in order to render it eaſy to thoſe who were not acquainted with the *Latin* Names, I have generally inſerted the ſeveral *Engliſh* Names, in their Order of the Alphabet, referring to the *Latin*, under which they are treated; and have alſo added an *Index* of the ſeveral Names by which each Plant is known, in which the Name is referr'd to, where it may be found.

After mentioning the *Genus*, I have added the *Etymology* thereof; and next have ſet down the diſtinguiſhing *Characters* by which each Plant is known, whereby a Perſon, who will attend to the ſeveral Characteriſticks, need not be at a Loſs where to refer a Plant he may not be well acquainted with; in this I have choſen to follow the Methods of *Tournefort* and *Boerhaave*, who have written ſo well on the Subject of Botany, that their Works are now generally read by every one who purſues that Study: Then I have inſerted moſt of the particular *Species* which are cultivated in *England*, either for Uſe or Beauty, with the beſt Methods for propagating and improving them; and the different Soils, Situations, and Degrees of Heat, in which each Plant is found to thrive. To this I have added their ſeveral Growths, with the proper Diſtance which each ſhould be allowed, whereby a Perſon may eaſily judge how to place them to the beſt Advantage in a Garden; and the various Uſes of them, whether for Meat or Medicine, or for the Beauty of their Flowers, *&c.* in adorning the Parts near a Habitation: In all which I have not aſſerted any thing upon Truſt, nor copied from many random Authors, who have written on this ſubject; but ſuch as I have experienced myſelf, or have received from Perſons of undoubted Authority.

I observed in my *Preface* to the former Editions of this Work, that the annual Increaſe of new Plants, Fruits and Flowers would occaſion ſome Alterations in the Book, in the Compaſs of a few Years, which has happen'd accordingly; for as new Things are obtain'd from abroad, ſo the old ones of leſs Value are turn'd out of the Gardens, to make room for them; which, however, has been, ſometimes practiſed with greater Freedom than Diſcretion, many Perſons having, for Novelty ſake, often turn'd out good Fruits to make room for bad ones; therefore I take the Liberty to repeat my humble Advice, that every one would make Trial of ſuch new Fruits before they propagate them in Plenty, and not take their Characters upon Truſt; and eſpecially to be careful how they are impos'd on by the new Names often given to Fruits, by Perſons of ſmall Skill, who, if they happen to meet with a Fruit with which they are not acquainted, preſently impoſe a Name of their own upon it, which has occaſion'd the preſent great Confuſion of that kind in different Places, to the no ſmall Diſcouragement of many curious Perſons in the Study of this Art: In order to remedy which in ſome meaſure, I have taken no ſmall Pains to examine and compare the ſeveral Sorts of Fruit, with the Deſcriptions given in all the beſt Authors, and have added as many of the Names to each Kind, as I could find they were differently known by; to which I have ſubjoin'd a ſhort Deſcription, with their Times of Ripening, and the particular Stocks upon which each Sort

Sort ſucceeds beſt, which I hope, will be of no ſmall Service to the Curious in that way.

Nor is the Confuſion of Names to the ſame ſort of Fruit peculiar to *England*; for in *France* (which has been eſteem'd the greateſt Fruit Country in *Europe*) there is as great a Diſorder, ſcarce any two Provinces calling a Fruit by the ſame Name; ſo that thoſe Trees which are brought from thence, are not more to be depended upon, than ſuch as are procured from the meaneſt Nurſeries in *England*. And this great Perplexity in the Names of Fruit has put ſome curious Gentlemen at *Paris*, upon compoſing a General Treatiſe of Fruit-Trees, in which they deſign to exhibit, on Copper Plates, all the ſeveral Kinds of Fruit, drawn from the Fruits themſelves, and well engraven. And 'tis certain, that if a Work of this Kind were carefully done by ſome judicious Perſons, with the Fruits exhibited in their proper Colours, and conciſe Deſcriptions, with their Culture, added to them, it would be a valuable Performance.

In the Preface to my former Editions, I alſo gave a Caution to my Readers againſt being too forward in propagating Foreign Trees in large Quantities, for the ſake of their Timber, till their Worth be fully known: This I think neceſſary to repeat, becauſe this Practice may, inſtead of being ſerviceable, prove greatly detrimental to the Nation, by neglecting to cultivate our own approved Timber Trees, for the ſake of others of foreign Growth, whoſe Timber is of little Value: An Inſtance of this we have lately had in the *Scarlet Oak*, a great Number of whoſe Acorns have been imported from *America*, and ſold at a large Price, with great Aſſurances of their quick Growth, and of the Value of the Timber, which hath engag'd many curious Perſons to ſow them; but if they cultivate theſe Trees in any Place, except in Gardens, or Plantations near Habitations, for Shade, (for which Purpoſe they are very proper, being of quick Growth) they will find themſelves deceived, the Timber being by no means comparable to our *Engliſh Oak*: However, many other Sorts of Trees there are in *America*, (particularly of the *Fir* Kind) which would be very ornamental to our Plantations, and their Timber very uſeful for many Purpoſes, were they once introduced amongſt us; and this will be found to take up no inconſiderable Part of my Attention in the Second Part.

Permit me to repeat finally, that with regard to Deſigns for *Gardens*, it would be only adding to the Expence of the Book, were I to have Engraved a great Number of Plates, ſince it is impoſſible to lay down Plans which may be ſerviceable to any one particular Deſign, becauſe theſe muſt be varied according to the Situation and Conveniencies of the Place: I have therefore only juſt mentioned the Particulars which ſhould be obſerved in laying out *Gardens*, leaving the other Parts to be ſupplied by thoſe who have the Direction of this Buſineſs.

I take this freſh Opportunity of returning my Thanks to thoſe Gentlemen who had been ſo kind as to favour me with their Remarks on the former Editions, and ſhall always be very thankful for any farther Notices of that Kind.

BRITISH MUSEUM 15 OCT 67

THE AUTHOR'S PREFACE TO THE SECOND VOLUME.

THE Publiſhing of this Second Volume of the *Gardener's Dictionary*, in a few Years after the Firſt, may poſſibly ſeem to require an Apology to the Publick, who have ſo kindly received my former Volume, leſt my omitting ſeveral Things in that, ſhould be interpreted as a Deſign, in order to furniſh Matter for another: But this I muſt declare was very far from my Thoughts; for at the Time when that Volume was compiled, I had room, as I thought, to apprehend, that it might not be ſo well received, after ſo many Books which had appeared on the ſame Subject in the Compaſs of a few Years before. Therefore I purpoſely omitted many Plants, which were not commonly cultivated in Gardens, leſt the Book ſhould ſwell to ſuch a Bulk, as might be an Obſtacle to the Sale, by making it too dear for the Generality of Readers. Some Plants had alſo eſcaped my Notice at that Time, of which I was ſoon informed by ſome of my Friends, who adviſed me to draw up an Account of their Culture, and to publiſh them in a ſmall Piece ſeparately, rather than to add them in any future Edition, that the Purchaſers of the former Volume might not be injured. And this being agreeable to my Reſolution and Promiſe to the Publick, in my firſt Edition, I the more readily complied with it, and accordingly publiſhed them as an Appendix to it, ſome Years ago. But as there has not been a proportionable Demand for them (few Perſons caring to purchaſe ſuch a ſmall Piece, after their Books were bound, as being ſubject to be miſlaid or loſt) ſo it is to be ſuppoſed that they will ſtill be new to a great many Perſons who purchaſed the firſt Volume.

Soon after the Publication of the Appendix, I received ſeveral Letters from Perſons of great Conſideration; in which they took Notice, that as the *Gardener's Dictionary* was now more generally conſulted than any other Book on the Subject, ſo the omitting of any uſeful Plant (however inconſiderable it might appear to ſome Perſons) was thought a Deficiency in the Work. By other Perſons I was informed, that as I had treated of ſeveral Things relating to *Agriculture* in the former Volume, ſo it would be acceptable to the Publick, if I were to communicate ſuch other Obſervations or Experiments as I ſhould have made relating to that Subject. For theſe Reaſons I employed my leiſure Hours in minuting down from my Papers all thoſe Things which might anſwer both Intimations, and be particularly uſeful to ſuch Perſons as were curious in making Improvements in Agriculture.

Theſe Articles, together with the ſeveral new Plants which I found it neceſſary to add, would have too much ſwelled the firſt Volume, had I been diſpoſed to add them to it, as, but for that Reaſon, and the Juſtice due to the Purchaſers of the firſt Edition thereof, I ſhould gladly have done in the laſt Impreſſion of that Piece: And having moreover ſeveral Catalogues and other Matters to add, at the Requeſt of divers worthy and judicious Friends, I thought it beſt, on all theſe Conſiderations, to publiſh all together, as a ſecond Volume, which ſhould complete my general Deſign, and yet in no ſort depreciate the Firſt.

Theſe Catalogues contain, firſt, the Names of the ſeveral Sorts of Trees and Shrubs which will thrive in the open Air in *England*, ranged according to their ſeveral Growths: by the Knowledge of which, ſuch Perſons as are not well acquainted with the Heights to which they uſually riſe, may know how to diſpoſe of them in Gardens, and other Plantations, ſo as to render them moſt ornamental.

The ſeveral hardy Flowers, which will thrive in the open Borders, and do not require Covering in Winter, are alſo, in the next place, ranged in a Catalogue, ſo that any Perſons may eaſily ſelect ſuch of them as are for their Purpoſe.

The next Catalogue is that of ſuch flowering Plants as will thrive under Trees in Wilderneſſes; which I have been often ſolicited to draw up, as what would be of no ſmall Uſe and Pleaſure to many curious Improvers.

To theſe are added Catalogues of tender exotic Plants, which are ranged according to the ſeveral Degrees of Heat they require in Winter; whereby any Perſon may be eaſily inſtructed how to diſpoſe them: for want of knowing which, many have placed ſome of the moſt tender exotic Plants, in common Green-houſes, amongſt Orange-trees and Myrtles, where they have been ſoon deſtroyed.

I have alſo added a Catalogue of ſuch of the Plants as are directed to be uſed in Medicine, as will thrive in the open Air in *England*; ſo that thoſe who are deſirous to cultivate them, may know which will thrive with them to Advantage; and I have diſtinguiſhed thoſe of them which grow wild in *England*, in ſuch a manner that any Perſon may know in what Soils and Situations they may be found; which will alſo be a Direction for their Culture, and is what many Perſons, eſpecially ſuch as live at a Diſtance from *London*, and have frequent Occaſion to make uſe of theſe Plants, have been deſirous of knowing.

In this Volume, I have alſo corrected ſome Miſtakes which had paſſed in the former: But as to the *eſſential Parts* of Gardening, I do not find, upon the moſt diligent Obſervation, that I have any Alterations to make; eſpecially in the Management of Fruit-trees, in which ſome Perſons differ from me at preſent; but from upwards of twenty Years Practice, I am convinced, that more Succeſs is not to be expected, in any other Method of Pruning or Management, than that which is laid down in the former Volume of the *Gardener's Dictionary*: for although, by a particular Method of Pruning, it is poſſible to have more Fruit for two or three Years; yet this will ſo weaken the Trees, that many times they are never to be recovered; and thoſe which are not ſo far reduced, cannot, with the beſt Management, be brought into good Order under ſeveral Years. So that where the future Welfare of Trees is conſulted, a moderate Share of Fruit is much to be preferred; which being better nouriſhed, are alſo always of a larger Size, and generally better flavoured; Conſiderations of much greater Eſtimation to all curious Perſons, than ſuch a Plenty as depreciates the Fruit, and exhauſts the Vigor of the Tree.

In treating on the Culture of the ſeveral Sorts of Plants herein mentioned, I have put down faithfully what is found by Experience to be the beſt Method; and if in this Article it ſhould be thought by any Perſons, that I have been too prolix, or that many of the Plants which I have enumerated, are to be met with but in few Gardens, I hope they will excuſe me, when they conſider that this is intended as a *Syſtem* of *Gardening*, in which it would be thought, by the judicious Part of Mankind, a much greater Fault to have omitted any Plants which are now cultivated in *England*.

The ſeveral Improvements which have of late Years been made in the Culture of exotic Plants, I have here inſerted, particularly of the *Anana*'s, which is now become common in moſt Parts of *England*; ſo that, from the various Experiments which have been made in its Culture, the Fruit of this Plant has been greatly improved, both in the Size and Flavour; whereby it is brought to a Degree of Perfection, very little inferior to that in Countries of its natural Growth. And as there have been ſeveral Methods practiſed in the cultivating theſe Plants, ſo there have alſo been ſeveral Contrivances of Stoves, in order to leſſen the Expence, and to bring the Fruit to a larger Size: for which Reaſon I have inſerted Plans of two Sorts of Stoves, which are found to anſwer theſe Purpoſes beſt; and have given ſuch plain Directions for their Structure, as, it is hoped, cannot be miſtaken, by any Perſon the leaſt converſant with ſuch Sort of Buildings.

I have alſo been pretty full in my Directions for building and managing of Hot-walls, either for accelerating the ripening of Fruit early in Summer, or for bringing ſuch late-ripe Fruit to Perfection; which cannot be obtained in this Country without ſuch artificial Helps: and as this Part of Gardening is at preſent much in Requeſt, ſo I have been the more careful to render the Inſtructions for it as plain as poſſible, that there ſhould not be any Miſtake made by thoſe who are deſirous to put them in Practice.

In the whole of this Work, I have endeavoured to lay down the Inſtructions given, in ſo plain and intelligent a Manner, as may make them eaſily underſtood by Perſons of all Capacities, who will but diligently apply themſelves to the practic Part: for all which Reaſons, I preſume to hope, that this additional Work may be found not altogether unworthy of the Indulgence of thoſe kind Perſons who have ſo favourably received my former Performance.

BRITISH MUSEUM 15 OCT 67

An EXPLANATION of the AUTHORS NAMES and WORKS, referr'd to by the Abbreviations in this WORK.

ALDIN. *A Deſcription of ſome rare Plants which were cultivated in the* Farneſian *Gardens at* Rome, *by* Tobias Aldinus. *Printed at* Rome 1625. Fol.

Baniſter. *A Catalogue of Plants obſerved in* Virginia *by* John Baniſter. *Printed in* Ray's *Hiſtory of Plants.*

Bocc. Rar. *Figures and Deſcriptions of rare Plants obſerved by* Paul Boccone *in* Sicily, &c. *Printed at* Oxford 1674. *in* 4to.

Boerh. Ind. *An Index of the Plants growing in the Phyſick-Garden at* Leyden, *by Dr.* Herman Boerhaave. *Printed at* Leyden 1719. *in* 4to.

THE

THE GARDENER'S DICTIONARY.

ABELE Tree. *Vide* Populus.

ABIES; The Firr Tree.

The Name is derived of *Abeo*, becauſe it advances much in Height; and for the ſame Reaſon it is by the *Greeks* called 'Ελάτη of 'ελάω, *promoveo*, *i. e.* to extend in Height; or, as others ſay, of *Abeo*, to go away, becauſe the Bark goes away, or is broken off eaſily.

The *Characters* of this Tree are;

It is ever-green; the Leaves are ſingle, and for the moſt part produced on every Side the Branches; the Male Flowers (or Catkins) are placed at remote Diſtances from the Fruit on the ſame Tree; the Seeds are produced in Cones, which are ſquamoſe.

The *Species* of this Tree, which are at preſent to be found in the *Engliſh* Gardens, are;

1. ABIES, *Taxi folio, fructu ſurſum ſpectante. Tourn.* The Silver *or* Yew-leaved Firr Tree.

2. ABIES, *Tenuiori folio, fructu deorſum inflexo. Tourn.* The Common Firr *or* Pitch Tree; *ſometimes called*, The Norway *or* Spruce Firr.

3. ABIES *Minor, pectinatis foliis, Virginiana, conis parvis ſubrotundis. Pluk. Alm.* The Virginian Firr Tree, with ſmall roundiſh Cones.

4. ABIES, *Taxi folio, fructu longiſſimo, deorſum inflexo.* The Yew-leav'd Firr Tree, with long hanging Cones, *commonly called*, The Long-con'd Corniſh Firr.

5. ABIES, *Piceæ foliis, brevibus, conis minimis. Rand.* The Pitch-leav'd Firr Tree, with ſmall Cones.

6. ABIES, *Piceæ foliis brevioribus, conis parvis, biuncialibus laxis. Rand.* The ſhorteſt Pitch-leav'd Firr Tree, with looſe Cones.

7. ABIES, *Taxi foliis, odora Balſami Gileadenſis. Raii Hiſt. App.* The Balm of Gilead Firr. *Vulgo.*

8. ABIES, *Taxi folio, fructu rotundiore, obtuſo.* The Yew-leav'd Firr Tree, with round Cones, *by ſome called*, The Balm of Gilead Firr.

9. ABIES, *Foliis prælongis, pinum ſimulans. Raii Hiſt.* Firr Tree, with long Leaves, reſembling thoſe of the Pine Tree.

10. ABIES *orientalis, folio brevi et tetragono, fructu minimo, deorſum inflexo. Tourn. Cor.* Eaſtern Firr Tree, with ſhort ſquare Leaves, and ſmall Fruit hanging downward.

11. ABIES *major Sinenſis, pectinatis taxi foliis ſubtus ceſiis, conis grandioribus ſurſum rigentibus, foliorum et ſquamarum apiculis ſpinoſis. Pluk. Amalth.* Great Firr-tree of *China*, with Yew Leaves, large Cones growing upright, and the Points of the Leaves prickly.

12. ABIES *maxima Sinenſis, pectinatis taxi foliis, apiculis non ſpinoſis. Pluk. Amalth.* Greateſt *China* Firr Tree with Yew Leaves, not prickly at their Points.

The firſt and ſecond Sorts of Firrs are very common in moſt Gardens, and Plantations of ever-green Trees; and the ſecond Sort is very common in the Woods of *Norway*, and is the Tree that affords the white Deals.

Theſe Trees were (not many Years ſince) much eſteemed for Ornaments in ever-green Gardens; but the Leaves and lower Branches decaying, and ſoon falling off, ſo as to render the under Part of the Tree bald and unſightly, together with their deſtroying every thing that grows under them, they are not at preſent in ſo much Requeſt.

The third Sort Dr. *Plukenet* mentions to have been formerly growing in the Biſhop of *London*'s Garden at *Fulham*, but hath been ſince deſtroyed, and hath been retrieved again from Seeds ſent from *New-England* by Mr. *Moore*, which were ſown by Mr. *Fairchild* of *Hoxton*, who raiſed ſeveral Plants from them, and finds it hardy enough to reſiſt our ſevereſt Cold in the open Ground.

The fourth Sort was brought, many Years ſince, from *America*, and was planted in *Devonſhire*, where are now large Trees of this Kind, which annually produce ripe Seeds, from whence the Gardens near *London* have been ſupplied. This Tree grows to be very large, and makes a beautiful Figure, the under Part of the Leaves being of a whitiſh, and the upper Part of a glaucous or Sea-green Colour, and are cloſely ſet upon the Branches. This Tree is alſo very hardy.

The fifth and ſixth Sorts were alſo brought from *America*, and planted in *Devonſhire* and *Cornwall*, and are, by the Inhabitants of thoſe Countries, uſed to make Spruce Beer, and are by them called the *Spruce Firrs*; but ſince any of theſe Sorts may be uſed for the ſame Purpoſe, this Appellation doth no more belong to theſe than any other of the Kinds.

Theſe Trees grow much cloſer and thicker than the *Common Firr*; nor are their Branches and Leaves ſo apt to decay and fall off, which renders them more valuable.

The ſeventh and eighth Sorts are promiſcuouſly called, *The Balm of Gilead Firrs*, but they are very diſtinct, according to the Branches which I had ſent me from *Devonſhire* and *Cornwall*. The ſeventh Sort Mr. *Ray* mentions in the Supplement to his *Hiſtory of Plants*, as growing in the Duke of *Beauford*'s Gardens at *Badmington*. It was alſo in the Biſhop of *London*'s Garden at *Fulham*, ſome Years ſince. This Sort produces long Cones, which are ſharp pointed, and ſtand erect upon the Branches, emitting a large Quantity of a reſinous Matter: the Branches grow flat, and the Leaves are very ſhort.

The other Sort produces Cones ſomewhat like thoſe of the Cedar of *Libanus*; the Leaves are of a darker Green, and are produced thicker on every ſide of their Branches, ſo that it is one of the beautifulleſt Trees of all the Firr kind.

The Leaves of theſe two Trees being bruiſed between the Fingers, emit a very ſtrong Balſamick Smell, which hath given Occaſion to ſome to believe that the *Balm of Gilead* was an Exudation from one of theſe Trees, from whence they received their Names; but this is known to be a Miſtake, that curious Balſam being the Production of a Tree very different from this Claſs.

The laſt four Sorts are, at preſent, very rare in *England*; the ninth was formerly growing in the Garden of Mr. *Edward Morgan* in *Weſtminſter*, a Branch of which Tree was given to Mr. *Ray*, by Mr. *Doody*, who was a very curious Botaniſt. The Leaves of this Tree are much longer than thoſe of any other kind of Firr yet known, but it hath not as yet produced any Cones in this Country.

The tenth Sort was diſcovered in the *Levant*, by Dr. *Tournefort*, who ſent the Cones to the Royal Garden at *Paris*. This Kind of Firr is very common in the Mountains of the *Archipelago*, from whence the Cones may be eaſily procured.

The other two Sorts are very common in *China*, from whence I have received Seeds and Branches of both kinds, but the Seeds having been taken out of their Cones before they were brought over, had dried up, and loſt their Germ, ſo that none of them grew; therefore, whoever is deſirous to propagate any of the Coniferous Trees, ſhould have the Cones gathered when ripe (before they open, and let out the Seeds) in which the Seeds will continue freſh a long Time: For if the Seeds are taken out of the Cones, they will not retain their growing Quality, ſo as to be tranſported from one Country to another.

All the Sorts of Firrs are propagated from Seeds, which may be ſown after the manner hereafter directed. The only Difference to be obſerved in their Culture, is, to ſhelter ſuch Sorts as come from a warmer Country, for two or three Winters, while they are young; after which Time all the Sorts of Firrs yet known, will thrive in the open Air in *England*: for there are none of them Natives of very hot Countries, and thoſe which do grow in Countries ten or fifteen Degrees more to the South than *England*, are always obſerved on Hills and Mountains, where they are expoſed to ſharp Froſts in Winter.

Moſt of the Firrs yet known delight in a pretty ſtrong deep Soil; tho' they will grow tolerably well on a light dry Soil for a few Years; but it has been often obſerved, That when the Trees are arrived to the Height of twenty or thirty Feet, on ſuch a Soil, they loſe their Verdure, and their under-Branches begin to decay; after which Time they ſeldom make any farther Progreſs, and many times a whole Plantation will ſuddenly decay. Nor will any of the kinds of Firr thrive in the Smoak of *London*: I don't remember to have ſeen one of theſe Trees of any Magnitude near *London*, tho' there are many of them yet remaining in ſome old Gardens, which have been many Years ſtanding, but are not above twenty Feet high, and in a very declining State.

The common Firr, which is a Native of *Sweden* and *Norway*, always grows in the Plains and low Grounds, where they have a great Depth of ſtrong loamy Soil, in which Places they arrive to a very great Height, tho' they are almoſt buried in Snow for ſeveral Months in Winter, ſo that theſe Trees might be cultivated in the low ſtrong Lands in the North of *England*, and in *Scotland*, where they would greatly improve ſuch Eſtates.

The ſeveral Sorts of Firrs, which are Natives of *America*, do generally grow upon low ſpringy Soils, and upon a light Ground, and ſuch of them which have been propagated in *England*, do thrive exceedingly upon low, light, moiſt Soils; whereas thoſe which have been planted on a drier Soil, have made very little Progreſs, and in very dry Seaſons many of them have quite periſhed, where they were not duly ſupplied with Water. Theſe are all very hardy in reſpect to Cold, ſo that they may be planted into the full Ground, when they are about a Foot high, into the Places where they are deſigned to remain.

The Silver Firr will thrive on a rocky Soil extremely well, provided the Rock be not too dry, in which Caſe they are very ſubject to die in very dry Seaſons, as hath been the Fate of ſome Plantations of theſe Trees a few Years ſince, which were grown to a large Size. The largeſt Trees of this kind which I have ſeen growing, were at *Farley* in *Hampſhire*; theſe were above eighty Feet high, and from ten to eleven Feet in Circumference. They grew in a ſtrong red clayey Soil, and upon Enquiry I found they had been planted near fourſcore Years.

The various Uſes of theſe Trees, either in Medicine, or for mechanical Uſes, are too many to be here enumerated, but whoever hath a mind to ſee theſe Things at large, may turn to *John Bauhin's Hiſtory of Plants*, Vol. I. Page 231. or to *Ray's Hiſtory of Plants*, where they will meet with an ample Account thereof.

Before I proceed to ſay any thing of the Culture of theſe Trees, I ſhall beg leave to add the Sorts of *Pines* to the *Firrs*, which altho' ſeparated to a great Diſtance by the Alphabetical Order here followed, yet have a near Alliance, both in their claſſical Diſtribution, and alſo in their Culture; and are, by the Unſkilful in Botany, frequently confounded together.

PINUS; The Pine Tree.

The *Characters* of this Tree are;

The Leaves are ever-green, longer than thoſe of the Firr, and are produced by Pairs out of each Sheath or Covering.

The *Species* of this Tree, to be found in the *Engliſh* Gardens, are;

1. Pinus *ſativa. C. B. Pin.* 491. The manured Pine.
2. Pinus *ſylveſtris. C. B. Pin.* 491. The Pinaſter, *or* Wild Pine.
3. Pinus *Americana, quinis ex uno folliculo ſetis, longis, tenuibus triquetris ad unum angulum, per totam longitudinem minutiſſimis crenis aſperatis. Pluk. Amalth.* 171. *This is commonly called* Lord Weymouth's Firr, *or* Pine.
4. Pinus *Americana, foliis prælongis ſubinde ternis, conis plurimis confertim naſcentibus. Cat. Plant. Ang.* The Cluſter, *or* Large Bunch'd Pine.
5. Pinus *ſylveſtris, foliis brevibus glaucis, conis parvis albentibus. Raii Syn.* 2. 288. The Scotch Pine, *commonly called* Scotch Firr.
6. Pinus *Americana, paluſtris.* The Swamp Pine. *Vulgo.*

The firſt, ſecond, and fifth Sorts are very common in *England*, but the third and fourth are in very few Gardens. The third was raiſed ſeveral Years ago in the Duke of *Beaufort*'s Gardens at *Badmington*, and is now growing in the Earl of *Pembroke*'s Gardens, where it thrives very well, and is become a large Tree.

In the Year 1724, ſome freſh Seeds of this kind were ſent over from *Carolina*, from which I raiſed ſome Plants in the *Phyſick* Garden, which, altho' but ſmall, ſtand in the open Ground, and reſiſt the Winter's Cold very well. The fourth Sort is now growing in the Biſhop of *London*'s Garden at *Fulham*, and is a very large Tree, producing ripe Cones almoſt every Year; from whence ſeveral young Trees have been raiſed by ſeveral Nurſery Men near *London*. The Leaves of this Tree are commonly three, produced from each Sheath; and the Cones grow in great Cluſters. On a Branch which was taken from the old Tree, I counted 39 Cones in one Bunch.

The ſixth Sort is very proper to continue Plantations of theſe ever-green Trees, when it may ſo happen that a moiſt ſwampy Soil may intervene (as it many times doth) between riſing Grounds, and in which Part we could not carry either the Avenue or other Plantation on with Trees of the ſame Kind, all the other Sorts being, for the moſt part, mountainous Plants; ſo that here is an Advantage which could not be other ways obtained, that ſhould encourage Gentlemen to cultivate as many of the Foreign Trees, as can be by any means naturalized to our Climate, tho' the Uſes of them are not immediately known; for it is certain that Time will diſcover ſomething, either for Uſe or Beauty, in moſt of them.

Beſide theſe, Mr. *Ray*, in his valuable *Hiſtory of Plants*, hath mentioned ſeven or eight other Species; but as there are at preſently ſcarcely any of them in *England*, and if they were brought hither by curious Perſons, their Culture would nearly agree with thoſe above mentioned; the only Difference to be obſerved, is to ſhelter ſuch as come from warmer Climates for two or three Years while they are young, after which Time I am perſuaded moſt of the reſinous Trees will do well with us abroad; therefore I ſhall forbear mentioning any more Sorts, referring the curious Reader to the valuable Book before cited.

Theſe Trees are all raiſed from Seeds taken out of their polyſpermous Cones. The Way to get out the Seeds, is either by expoſing the Cones to a gentle Fire, or by ſoaking them all Night in Water, which will cauſe their ſquamoſe Cells to open, and readily emit their Seeds; but this ought not to be done until you are ready to ſow them, which is beſt perform'd in the Beginning of *March*.

BRITISH MUSEUM 15 OCT 67

The Manner of ſowing them (if for large Plantations) is as followeth: After your Ground hath been plow'd to looſen the Earth, and deſtroy the Weeds, (eſpecially if the Ground is ſubject to Heath or Furze) it muſt be plough'd two or three times, and the Roots carefully grubb'd up, the more effectually to deſtroy theſe ſpreading Plants, which would otherwiſe ſoon over-run and ſpoil your young Plantation. This being done, you may with a Spade, level the Earth in ſmall Spots at about every ſix Feet ſquare: In which Spots you may ſow ten or twelve Seeds, covering them about a quarter of an Inch thick with ſome of the ſame Mould broken fine, and the great Stones taken out, (but not ſifted, for Reaſons hereafter mentioned) when this is done, it will be a good Way to lay upon each of theſe Spots ſome Peas Haulm, Furz, or any other light Covering, to prevent the rapacious Birds from deſtroying your young Plants juſt as they peep out of the Ground (they being very fond of the Huſk or Coat of the Seed, which the young Plants bring up on their Heads;) which Covering will alſo prevent the drying Winds and Sun from piercing the Ground and deſtroying your Seed. This covering may remain ſome time after the Plants are come up, provided it is not laid over thick, nor too cloſe, which would thereby draw and weaken the Plants, by preventing the Ingreſs of the Air. When this Haulm or Covering is taken off, it will be neceſſary to draw a little looſe Earth round the Stems of your young Plants, to ſtrengthen them, as alſo to ſtick ſome Furze over them, to prevent the Sun from ſcorching them, which is very hurtful to theſe Plants while young. In each of theſe Spots (if your Seed was good) you may reaſonably expect 6 or 8 Plants to come up, which may remain together until the third Year; but in the mean time it will be a very good Way to preſerve your young Plants, to lay a little Litter, or ſome Mulch upon the Surface, and round the Stems of the Plants, to guard againſt ſevere Froſts in Winter, and extreme Drought in Summer. This being carefully performed, will ſave the Trouble of Watering, and be more ſerviceable to your Plants.

The third Year after ſowing, you may remove ſome of theſe Plants into another Plantation (which Ground ought to be prepared as before directed.) The beſt Seaſon for this Work is towards the latter End of *March*, and Beginning of *April*, the Weather mild, but not when the Eaſterly drying Winds blow, which preſently dry the ſmall Fibres of theſe Plants when out of the Ground. The Diſtance theſe Trees ought to be planted (if for a cloſe Plantation) may be about eight Feet ſquare, which Diſtance will be found ſufficient; for if they be planted at too great a Diſtance, they are ſubject to ſhoot out many lateral Branches, which will retard their upright Growth.

In removing theſe Plants, they ſhould be taken up with as much Earth as poſſible, but Care muſt be had not to hurt the Roots of thoſe Plants left in theſe ſmall Spots, which ſhould be two of the beſt Plants in each, and filling up the Holes made in taking out the Plants, with ſome of the neighbouring Mould, to prevent the Extremity of their Fibres from drying.

When your Plants are ſet in the new Plantation, a Quantity of ſmall Stakes ſhould be provided to faſten the young Trees, that the Wind may not blow them out of the Ground, and beſure cover the Roots with ſhort Litter, as before directed; then give them a gentle Watering to ſettle the Earth to the Roots; and if the Weather ſhould prove very dry, you may repeat this gentle Watering two or three times; but be ſure not to over water, which, I may venture to ſay, hath killed more new-ſet Trees of all Sorts, than the want of Water, or any other Accident whatever; therefore once for all, I would adviſe to have eſpecial Regard that all new-ſet Trees are well mulch'd with ſhort Litter, or Mulch, but to have a great care not to water too much, nor too often, which rots the young Fibres as faſt as they are puſh'd forth, as I have often experienced; and have a great care not to cut any of the Branches or Heads of theſe Trees, which is very hurtful, eſpecially to all thoſe of the reſinous Kind.

The Soil in which the *Scotch* Pine delights, is chalky Hills: And where there have been not above ſix or eight Inches of Mould upon the Surface, I have ſeen the moſt vigorous Trees; as at a Seat belonging to the Hon. Sir *John Guiſe*, near *Great Marlow* in *Buckinghamſhire*, where there are vaſt Numbers of theſe Trees which drop their Seeds, and ſpring up without any Care or Culture. Notwithſtanding theſe Trees chiefly delight in the before-mentioned Soil, yet will they thrive tolerably well in a poor Gravel, (provided it be not too light and ſandy) or in a ſtrong Soil, (if not too wet) but they love a moderate Elevation, and will grow on the North or Eaſt Side, or even upon the Summit of high Hills.

The Common, or Spruce Firr, requires a ſtrong Soil, and is commonly a Native of the low Grounds, and Plains, in *Norway* and *Sweden*, where the Soil is deep, and of a ſtrong loamy Nature; whereas the *Scotch* Pine grows on the Hills and Rocky Parts of thoſe Countries, where there is ſcarce any Earth upon the Surface, their Roots ſtriking into the Fiſſures of the Rocks.

Moſt of the *American Firrs* and *Pines* do delight in a moiſt looſe Earth, in which they will make great Progreſs; but in a very dry Situation they will ſcarcely live, as may be ſeen by many Plantations which have been made with theſe Trees of late.

The *Silver Firr*, and the manured *Pine*, will grow in a drier Situation, but they require a deeper Soil than the *Scotch Pine*, and ſhould not be too much expoſed to the North or Eaſt Winds, which often deſtroy theſe Plants while they are young.

Theſe Trees do not delight in dunged or rich Soils: but obſerve, it is much the better Way to train up any ſort of Plant in a Soil nearly akin to that you intend to plant them in, and not (as is too often the Practice) make a Nurſery upon a good rich Soil, when the Trees there raiſed are deſigned for a poor barren Soil; and this I believe to be the Reaſon why Plantations of Trees procured from rich Nurſeries are often ſeen to make but a poor Progreſs, if they live.

The two Trees left in each Spot, ſhould not continue longer than ſix or ſeven Years together, when you ſhould remove the leaſt thriving Tree, leaving only one of the ſtrongeſt in each Place; in the doing of which, great Care ſhould be taken not to diſturb the Roots of thoſe left. The Seaſon for this Work is before directed. Theſe Trees which you now remove, will be of great Service for planting Viſta's, or Amphitheatres of Ever-greens, or for Clumps in different Parts of Wilderneſſes; in the doing of which, obſerve to plant the *Scotch Pine* and *Pinaſter* on the backward Part of theſe Plantations, theſe being the quickeſt and largeſt growing Trees (in our Country) and are the beſt able to reſiſt ſtrong Winds.

But I ſhall return to give ſome Account of the Way practiſed in raiſing theſe Trees, in ſmaller Nurſeries, for the planting Avenues, or other Lines of Trees, which Method will do very well for the *Cedar*, *Larch*, or moſt other exotick Trees of theſe Kinds (provided they come not from too hot a Country.) You muſt provide yourſelf with ſome ſhallow Caſes, not above ſix or eight Inches deep, and in Length and Breadth in Proportion to the Quantity of Seeds deſigned to be ſown therein; but I would adviſe not to have them too big, which will render them immoveable, and it is upon this Account I chuſe to have them ſowed in Caſes, *viz.* That they may be moved to any Poſition, and, if need be, carried into Shelter, in the Winter. The Bottom of theſe Caſes ſhould be bored full of Holes to let out the ſuperfluous Moiſture. Upon each of theſe Holes, ſhould be laid a Piece of Tile, or an Oyſter Shell, to prevent the Earth from ſtopping the Holes; and if the Bottom of the Caſes were covered with ſmall Stones, or any dry Rubbiſh, it would the better drain off the Moiſture, and keep the Soil looſe about the Roots of the young Plants.

The Soil which I chiefly prefer to fill theſe Caſes with, ſhould be taken from Paſture Ground, not too ſtiff, nor over-light. This ſhould have a Mixture of Lime Rubbiſh, and (if inclining to a Clay) ſhould alſo have a good Quantity of Sea-Sand mix'd therewith, and by no means ſift or ſkreen this Mould, as is moſt commonly practiſed, but only take out the very large Stones, which might obſtruct the Growth of your Plants: for when all the Stones are ſifted out of Mould, the ſmaller Particles of Earth do ſo cloſely join together, as in wet Weather to become one ſolid Maſs, and thereby prevent the Moiſture from draining off, which will rot the Fibres of whatever is planted or ſown therein; and when the Heat of Summer comes on, the Surface of this ſifted Earth will be dried to a hard Cruſt, ſo as to prevent the Moiſture from equally penetrating it.

Your Caſes being filled as before directed, lay the Surface of the Mould even, and thereon ſow your ſeeds pretty thick, covering it with ſome of the ſame Earth broken fine, about a quarter of an Inch thick, laying thereon ſome Furze, as before directed. Theſe Caſes ſhould be placed to have the Morning Sun, but muſt be ſkreened from the Sun in the Heat of the Day, by Trees or Hedges; but by no means place them near a Wall or Pale, which would reflect too great a Heat upon them, and would very much prejudice the Plants while young. Theſe Caſes ſhould be gently watered whenever there may be Occaſion; but remember not to over-water, as was before hinted.

The Seaſon for this Sowing, is the ſame as was directed for larger Plantations. A little after *Michaelmas* it will be convenient to remove ſome of the Earth upon the Surface, which, by this time, will often grow moſſy; but this muſt be done with abundance of Care, leſt the young Plants ſhould thereby be diſturb'd; and then lay thereon a little dry freſh Earth, (well mix'd with Rubbiſh, or Sand, to keep it from retaining the Wet) obſerving not to let any of it remain upon the Tops of your young Plants: This will ſtrengthen them the better to endure the Winter's Cold: And at this Time it will be convenient to remove the Caſes into a warmer Situation, as under ſome South Hedge, and raiſe them from the Ground with Bricks, that they may be kept the drier; and if it proves froſty, it will be neceſſary to lay ſome Furze (or ſuch like light Covering) to guard them from the Injuries thereof; but I would not adviſe the Houſing, unleſs they are of ſuch Sorts as are brought from hotter Countries. They may remain in theſe Caſes till the ſecond Year, at which Time it will be convenient to remove them into Nurſeries, where they may ſtand for four or five Years. The beſt Seaſon for this Work, is towards the latter End of *March*, or the Beginning of *April*. The Manner of performing it being the ſame as was directed for larger Plantations, I ſhall refer to that; only I muſt beg leave to obſerve, that if the Soil you intend to plant them in, be a ſtrong Clay, it will be neceſſary to raiſe a little Hill of lighter Earth, whereon to plant each Tree; and if Trees of this kind are removed at a larger Growth, it will be abſolutely neceſſary to raiſe a Hill for each Tree, (as alſo if the Soil be a Gravel or Chalk) and not, as is too often the Practice, dig a Hole into the Gravel, Chalk, or Clay, and fill it with Mould, and therein plant the Tree. This is next akin to planting them in Ciſterns, which will hold the Water, and rot the Fibres: And if it ſo happens that the Trees live four or five Years, yet, after that, when the Roots are ſpread to the Extremity of theſe Holes, and can get no farther, the Trees grow knotty and ſtunt, and, perhaps, in a few Years, die. The not obſerving this, is the Reaſon we ſee ſo few Plantations in ſo thriving a State as might be wiſh'd for.

Theſe Trees are very often at a Stand, during three or four Years after Planting; but when once they have eſtabliſh'd themſelves in their new Quarters, will ſufficiently recompence for that, by ſhooting near a Yard annually; and ſome of theſe Trees will grow to a prodigious Magnitude; as ſometimes to above an hundred Feet: And it hath been a Matter of Concern, to ſeveral ingenious Perſons, that theſe Trees have not been more propagated, ſince they have ſo many Excellencies to recommend them, *viz.* 1. The Facility of their Propagation. 2. Their delighting to grow in ſuch Places where few other Trees will grow. 3. Their requiring no Culture or Dreſſing, after the firſt five or ſix Years. 4. Their Uniformity and Beauty. 5. Their perpetual Verdure and Sweetneſs: And laſtly, their great Uſefulneſs in many Parts of Life. The Whole of which may be ſeen at large in that Valuable *Hiſtory of Plants* written by Mr. *Ray*, Vol. II. Page 1400, *&c.*

The Seeds of theſe Trees, if preſerved in the Cones, will keep good for many Years. I have been inform'd of a Gentleman who ſow'd ſome Pine Seeds which were taken out of a Cone upwards of twenty Years old, and had ſome Plants from them; but from my own Knowledge, I can aſſure, that Seeds taken from Cones five Years old, grow very well, which is of ſingular Uſe to know; for ſince their Seeds will grow ſo old, we need not deſpair of bringing them from the moſt diſtant Parts of the World, (provided they are brought in the Cones) for otherwiſe they will keep but a ſhort time, which is the Reaſon why the Seeds of the *Silver Firr* are ſo rarely good; for the Cones of this Tree, when ripe, fall to pieces on the firſt Touch, and ſcatter out their Seeds, but the Seeds of all the Kinds of Pines are with ſome Difficulty taken out of the Cones; therefore it would be a very good Method to preſerve the Seeds of Firrs in dry Sand, until the Spring of the Year, which is the proper Seaſon for ſowing them.

ABROTANUM, or Southernwood; ['Αβρήτανον, which ſome derive of ʼΑβροτον, inhuman, becauſe of its being bitterer than Wormwood itſelf: With us it takes its Name from the *Anglo-Saxon* Soðeꞃn-ƿuðu, *Southern-wood.*]

This Plant is better known by its outwand Appearance, than by any diſtinct Characters which can be given of it, agreeing in moſt Parts with the *Wormwood*, from which it is not eaſy to ſeparate it.

Of this Plant there are ſeveral different Sorts, which are Natives of *Europe*; but the firſt two are the moſt common with us in the *Engliſh* Gardens.

1. Abrotanum, *Mas anguſtifolium majus. C. B. Pin.* Common Southernwood.

2. Abrotanum, *Mas anguſtifolium minus. C. B. Pin.* The Leſſer and Narrower-leaved Southernwood.

3. Abrotanum *mas anguſtifolium max. C. B. P.* Greateſt narrow-leav'd Southernwood.

4. Abrotanum *latifolium inodorum. C. B. P.* Broad leav'd Southernwood, without Scent.

5. Abrotanum *mas anguſtifolium incanum. C. B. P.* Hoary narrow-leav'd Southernwood.

6. Abrotanum *campeſtre, cauliculis albicantibus. C. B. P.* Fine leav'd wild Southernwood, with whitiſh Stalks.

7. Abrotanum *campeſtre, cauliculis rubentibus. C. B. P.* Fine leav'd wild Southernwood, with reddiſh Stalks.

8. Abrotanum, *campeſtri ſimile, Tingitanum. H. L.* Tangier Southernwood reſembling the wild Sort.

9. Abrotanum *campeſtre incanum, carlinæ odore. C. B. P.* Hoary Field Southernwood, with a Smell like the Carline Thiſtle.

10. Abrotanum *humile, corymbis majoribus aureis. H. R. Par.* Dwarf Southernwood, with larger Golden Flowers.

11. Abrotanum *Hiſpanicum, abſinthii Pontici folio. Tourn.* Spaniſh Southernwood, with a Pontick Wormwood Leaf.

12. Abrotanum *Hiſpanicum maritimum, folio craſſo ſplendente et rigido. Tourn.* Spaniſh Sea Southernwood, with a thick, ſhining, ſtiff Leaf.

13. Abrotanum *mas ex Surinam, molli hirſutiæ caneſcens. Pluk. Almag.* Hoary Male Southernwood from *Surinam*.

14. Abrotanum *elatius ſubincanum, foliis creberrimis, ſecundum caulem in metæ formam faſtigiatis. Pluk. Almag.* Taller hoary Southernwood, with frequent Leaves gathered into a kind of Pyramid.

15. Abrotanum *orientale annuum, abſinthii minoris folio. Tourn. Cor.* Annual Eaſtern Southernwood, with a Leaf of the leſſer Wormwood.

16. Abrotanum *orientale, chamæmeli folio. Tourn. Cor.* Eaſtern Southernwood, with a Camomile Leaf.

17. Abrotanum *Africanum, foliis argenteis anguſtis, floribus ſpicatis, capitulis copioſo tomento donatis. D. Sherard. Raii Supp. African* Southernwood, with narrow Silver Leaves, ſpiked Flowers, and very woolly Heads.

18. Abrotanum *Africanum, foliis argenteis anguſtis, floribus umbellatis, capitulis tomentoſis. Raii Supp. African* Southernwood, with narrow Silver Leaves, umbellated Flowers, and woolly Heads.

The firſt two Sorts are eaſily increaſed, by planting Cuttings, in a ſhady Place, in any of the Spring or Summer Months. The firſt of theſe Sorts is ſometimes uſed in Phyſick, being accounted good to deſtroy Worms in Children.

It is uſed in Gardens as an Under-ſhrub, and may be kept to a handſome round Head; but it is chiefly raiſed by the Gardeners near *London* to furniſh the Balconies of the Citizens, in the Spring and Summer Months, it enduring the Smoak of the City better than moſt other Shrubs or Plants, and affords (to ſome People) a grateful Smell.

The third, fourth, and fifth Sorts may be propagated by Slips or Cuttings, in the ſame Manner as the firſt and ſecond. Theſe are, at preſent, more rare in the *Engliſh* Gardens, tho' they are equally hardy with the other Sort; and may be planted for Under-ſhrubs, in quarters of low growing Trees, where, by the Diverſity of their Leaves, they will afford an agreeable Variety.

The ſixth and ſeventh Sorts grow commonly in *Germany*, *Italy* and *Narbonne*, by Way-ſides, and in barren Places, and are alſo found in *England* by the Way-ſide from *Newmarket* to *Lyn*, near a Village called *Elden*. Theſe ſeem to be but Varieties from each other, and only differ in the Colour of their Stalks. They are ſeldom preſerved in Gardens, unleſs it be for Variety, by ſome Botaniſts. Whoever is deſirous to have theſe Plants, may eaſily obtain them from the Places of their Growth, either the Plants, or the Seeds, but the Seeds ſhould be ſown ſoon after they are ripe, for they being very light, will loſe their growing Quality, if they are kept long out of the Ground. Theſe Plants ſeldom continue above three or four Years, when tranſplanted into Gardens, ſo that new ones ſhould be raiſed from Seed to ſucceed them.

The eighth Sort is not ſo hardy as any of the former, for being a Native of warm Countries, it requires to be ſheltered from the Froſt in Winter. This may be propagated as the former, but ſhould be kept in Pots, that they may be placed under a Frame in Winter, where they ſhould have as much free Air as poſſible in mild Weather, but in hard Froſts may be covered with Glaſſes and Mats to ſecure them.

The ninth Sort ſhould be treated in the ſame Manner as the ſixth or ſeventh Sorts, and is equally hardy. Theſe will continue much longer on a dry barren Soil, than when they are planted in a rich Garden Earth.

The tenth, eleventh, twelfth and ſixteenth Sorts, may be propagated by Seeds, or from Slips and Cuttings: If from Seeds, they ſhould be ſown on a warm Border of dry Earth early in the Spring, and when the Plants are come up, they muſt be conſtantly kept clear from Weeds, which if ſuffered to grow, would ſoon over-bear and deſtroy the young Plants. When the Plants are about four Inches high, ſome of them may be planted into Pots, that they may be removed under Shelter in the Winter; and the others may be tranſplanted into a warm Border, obſerving to ſhade and water them until they have taken new Root; after which time they will require no farther Care, but to keep them clear from Weeds. Theſe Plants are ſometimes deſtroyed by ſevere Froſt, while they are young, but afterwards they will endure the Cold of our ordinary Winters extremely well; eſpecially if they are planted on a dry lean Soil. If you propagate theſe by Slips or Cuttings, they muſt be treated in the ſame Manner as hath been directed for the common Sort.

The thirteenth and fourteenth Sorts are tenderer than any of the beforemention'd. Theſe may be propagated either by Seeds, or from Slips, as the former; but they muſt be kept in Pots, and require a good Greenhouſe in Winter, where they ſhould be placed to enjoy as much free Air as poſſible in mild Weather.

The fifteenth Sort is an annual Plant, which rarely produces good Seeds in this Country. The ſureſt Method to obtain good Seeds is to raiſe the Plants towards the latter part of Summer, and preſerve the Plants thro' the Winter, which will cauſe them to flower early the following Summer, ſo that they will have time to perfect their Seeds; whereas thoſe which are raiſed in the Spring, will flower late in the Autumn, and the cold Weather will come on before they have time to ripen Seeds.

The ſeventeenth and eighteenth Sorts do rarely produce good Seeds in *Europe*, but they may be eaſily propagated by Cuttings or Slips, which ſhould be planted in Pots filled with light freſh Earth, and plunged into a very moderate hot Bed, obſerving to water and ſhade them until they have taken Root, after which Time they ſhould be inured to bear the open Air by Degrees; then they ſhould be taken out, and placed where they may have the morning Sun, and ſheltered from the ſtrong Winds, in which Situation they ſhould remain till *October*, when they ſhould be removed into the Green-houſe, and placed where they may enjoy as much free Air as poſſible in mild Weather, and muſt be frequently refreſhed with Water; but they muſt be ſecured from Froſt, otherwiſe they will be deſtroyed.

ABROTANUM FŒMINA. Vide *Santolina.*

ABSINTHIUM, Wormwood; [Ἀψίνθιον, *q. d.* Unpleaſant, from ἀ ςερητικȣ͂, Privative, and ψίνθος, which *Heſychius* interprets τέρψις, Delectation.] It is called in *Engliſh* from the *Anglo-Saxon* Ƿẏꞃm-ƿẏꞃꝣ, *i. e.* Wormwort.

The *Character* of this Plant is,

To have an indeterminate Stalk, branching out into many ſmall Shoots, which are furniſh'd with Spikes of naked Flowers hanging downward; the Leaves are hoary, and of a bitter Taſte.

The *Species* are,

1. ABSINTHIUM *vulgare majus. J. B.* Common Wormwood.

2. ABSINTHIUM *Ponticum tenuifolium incanum. C. B. Pin.* True *Roman* Wormwood.

3. ABSINTHIUM *maritimum lavendulæ folio. C. B. Pin.* Sea Wormwood, with Leaves like Lavender.

4. ABSINTHIUM *inſipidum, abſinthio vulgari ſimile. C. B. Pin.* The inſipid Wormwood is ſo like the common, as not eaſily to be diſtinguiſh'd, but by ſmelling and taſting the Herb, unleſs by ſuch as are very ſkilful in Botany; but this Sort is not very commonly met with in *England.*

5. ABSINTHIUM *arboreſcens. Lob. Icon.* 753. Tree Wormwood.

6. ABSINTHIUM *Ponticum montanum. C. B. P.* Common Mountain Wormwood.

7. ABSINTHIUM *Ponticum Creticum, grati odoris. C. B. P.* Candy Pontick Wormwood, of a pleaſant Smell.

8. ABSINTHIUM *Ponticum tenuifolium, caulibus purpuraſcentibus, foliis ſupina parte viridioribus. C. B. P.* Narrow-leav'd Pontick Wormwood, with purpliſh Stalks, and Leaves greener on their under Side.

9. ABSINTHIUM *Ponticum tenuifolium Auſtriacum. C. B. P. Auſtrian* Wormwood.

10. ABSINTHIUM *Ponticum, repens vel ſupinum. C. B. P.* Creeping Pontick Wormwood.

11. ABSINTHIUM *maritimum, foliis ſuperioribus in aliquot lacinias diviſis. C. B. P.* Sea Wormwood, with the upper Leaves divided into ſome Jags.

12. ABSINTHIUM *Seriphium Germanicum. C. B. P.* German Sea Wormwood.

13. ABSINTHIUM *Seriphium Belgicum. C. B. P.* Belgick Sea Wormwood.

14. ABSINTHIUM *maritimum, Seriphio Belgico ſimile, latiore folio, odoris grati. Pluk.* Sea Wormwood, reſembling the Belgick Wormwood, with a broader Leaf, and a pleaſant Smell.

15. ABSINTHIUM *Seriphium Gallicum. C. B. P.* French Sea Wormwood.

16. ABSINTHIUM *Santonicum Gallicum. C. B. P.* French Wormwood.

17. ABSINTHIUM *Seriphium montanum candidum. C. B. P.* White Mountain Wormwood.

18. ABSINTHIUM *Alpinum incanum. C. B. P.* Hoary Wormwood of the *Alps.*

19. ABSINTHIUM *Alpinum, candidum humile. C. B. P.* Dwarf white Wormwood of the *Alps.*

20. ABSINTHIUM *Seriphium Hiſpanicum, flore oblongo. Tourn. Spaniſh* Wormwood, with an oblong Flower.

21. ABSINTHIUM *Halepenſe, grati odoris, coma delicatiore. Pluk.* Wormwood of *Aleppo*, of a pleaſant Smell, with a delicate Spike.

22. ABSINTHIUM *Africanum, arboreſcens, folio vermiculato incano. Oldenl. African* Tree Wormwood, with a hoary vermiculated Leaf.

23. ABSINTHIUM *Africanum ſpicatum, foliis tenuiſſimis & breviſſimis integris. D. Sherard. Raii Supp.* Spiked *African* Wormwood, with narrow ſhort intire Leaves.

24. ABSINTHIUM *maritimum noſtras. D. Preſton. Raii Supp. Scotch* Sea Wormwood.

25. ABSINTHIUM *orientale fruticoſum incanum, amplo folio tenuiſſime diviſo. Tourn. Cor.* Shrubby *Eaſtern* Wormwood, with large hoary Leaves finely divided.

26. ABSINTHIUM *orientale incanum, capillaceo folio, floribus in capitulum congeſtis. Tourn. Cor.* Hoary Eaſtern Wormwood, with a capillaceous Leaf, and Flowers collected into an Head.

27. ABSINTHIUM *orientale incanum tenuifolium, floribus luteis, in capitulum congeſtis & ſurſum ſpectantibus. Tourn. Cor.* Hoary narrow-leav'd Eaſtern Wormwood, with yellow Flowers collected into an Head, and looking upward.

28. ABSINTHIUM *orientale incanum, tanaceti folio, inodorum. Tourn. Cor.* Hoary Eaſtern Wormwood, with a Tanſy Leaf, without Smell.

29. ABSINTHIUM *orientale tenuifolium, argenteum & ſericeum flore magno. Tourn. Cor.* Eaſtern Wormwood, with narrow ſilver colour'd ſilken Leaves.

30. ABSINTHIUM *orientale vulgari ſimile, ſed longe minus amarum. Tourn. Cor.* Eaſtern Wormwood, like the common, but far leſs bitter.

31. ABSINTHIUM *orientale tenuifolium incanum, odore, lavendulæ & inſipidum. Tourn. Cor.* Hoary narrow-leav'd Eaſtern Wormwood, with a Lavender Smell, and inſipid.

32. ABSINTHIUM *orientale tenuifolium incanum, lavendulæ odore, & amarum, flore deorſum ſpectante. Tourn. Cor.* Hoary narrow-leav'd Eaſtern Wormwood, with a Lavender Smell, and bitter, with the Flower hanging down.

The firſt of theſe Sorts is very common in *England*, in the Roads and upon Dunghills; but it is alſo planted in Gardens, for common Uſe: The ſecond, third, and fourth Sorts are only found in curious Gardens of Plants. They are all eaſily raiſed, by planting of Cuttings and Slips, in any of the Summer Months. The Roman and Sea Wormwoods are great Creepers at the Root, and will ſoon ſpread over a large Piece of Ground. The Tree Wormwood riſes to be a Shrub five or ſix Foot high, and is kept in Gardens as a Rarity, and was formerly preſerved in Green-houſes, but hath been found hardy enough to endure our Winters abroad, if planted in Places ſheltered from the Northern Winds: This Shrub makes an agreeable Variety, in ſmall Quarters of Ever-greens or Flowering Shrubs; the hoary Leaves, which continue all the Year freſh, ſtrike the Eye at a great Diſtance, and have a good Effect in diverſifying the Proſpect: This Shrub is eaſily raiſed from Cuttings planted in any of the Summer Months, (under a Hedge or Wall) where they may have only the Morning Sun; and being frequently water'd, will take Root in a Month or ſix Weeks Time, when they may be removed to the Places where they are deſign'd to remain; obſerving in this (as in many other Shrubs and Plants which are Natives of a warmer Climate) to place them in a dry Situation: Wet, eſpecially in Winter, is the moſt deſtructive to all theſe Sorts of Plants.

The twenty-fifth Sort, being a Shrub, muſt be propagated by Cuttings, after the Manner directed for the firſt Sort. This muſt be kept in Pots, that they may be removed into the Green-houſe in Winter, becauſe in very ſevere Froſt it is often deſtroyed, tho' in mild Winters it will live in the open Air, provided it is planted on a dry Soil, and in a warm Situation.

The twenty-ſecond and twenty-third Sorts are Natives of the *Cape of Good Hope*; theſe Sorts may alſo be propagated by planting either Cuttings or Slips in any of the Summer Months, obſerving to water and ſhade them until they have taken Root; then they may be placed abroad amongſt other Exotick Plants, where they may remain till *October*, when they muſt be removed into the Green houſe, and placed with *Myrtles* and other hardy Plants, which require a large ſhare of free Air in mild Weather, and only want Protection from ſevere Froſts. They will require to be frequently watered in mild Weather, and ſhould have a light freſh Soil. The twenty-ſecond Sort will riſe to the Height of ſeven or eight Feet; but the twenty-third Sort is an humble Plant. Theſe ſeldom produce Seeds in *Europe*.

All the other Sorts are low Plants, which may be propagated by their Roots, many of which are apt to creep too much, ſo as to render it difficult to keep them within Compaſs. Theſe do many of them die to the Ground in Autumn, and riſe again the following Spring. The beſt Seaſon for tranſplanting theſe Plants is in *March*, juſt before they begin to ſhoot; they will grow in almoſt any Soil or Situation, but the Eaſtern Kinds ſhould be planted in a warmer Place than the other Sorts. They ſhould be planted in Beds about four Feet broad, with Paths two Feet broad between each Bed, for the more convenient cleaning them from Weeds, and for gathering the Herb for Uſe. The Diſtance which ſhould be allowed to the Plants, ought not to be leſs than eighteen Inches, or two Feet, becauſe as they are great Runners by their Roots, ſo they will ſoon meet and ſpread over the whole Beds. They may remain in theſe Beds three or four Years, and will require no other Culture, but to keep 'em clear from Weeds, and every Spring before they ſhoot, to cut off their dead Stalks, and ſpread a little freſh Earth over the Beds. At which time you ſhould dig up the Paths between the Beds, and cut off the Roots which may have ſpread into them, otherwiſe they will ſoon over-run the Paths.

There are a great Variety of the *Sea Wormwoods*, which grow plentifully on the ſalt Marſhes, in diverſe Parts of *England*, which are indifferently gathered and brought to the Markets, and ſold for the *Roman Wormwood*, from which they differ greatly, in the Colour of their Leaves, as alſo in their Taſte and Smell; but by many Perſons the *Sea Wormwoods* are preferred to the true *Roman Wormwood*, as having a ſtronger and more grateful Scent; tho' the *Roman Wormwood* is thought to be leſs nauſeous to the Stomach. However, as that is now generally diſuſed, it would be to little Purpoſe to recommend it, ſince it would be difficult to alter a Practice which has been ſo long continued.

ABUTILON, [the Name is *Arabick*] Yellow Mallow.

The *Characters* of this Plant are;

It hath the whole Appearance of the Mallow, in both Leaves and Flowers; the Flower hath a ſingle Cup; the Seeds, which are ſhaped like a Kidney, are each of them lodged in a ſeparate Cell.

There are ſeveral *Species* of this Plant known in *Europe*; as,

1. **Abutilon.** *Dod.* The common Yellow Mallow.

2. **Abutilon** *Indicum. J. B.* The *Indian* Yellow Mallow.

3. **Abutilon** *Carolinianum reptans alceæ foliis gilvo flore. Act. Phil.* The *Carolina* Abutilon, with Leaves like the Vervain Mallow.

4. **Abutilon** *Americanum ampliſſimo folio caule villoſo. Plum.* The large-leav'd *American* Abutilon, with woolly Stalks.

5. **Abutilon** *Americanum, fructu ſubrotundo, pendulo, è capſulis veſicariis cripſis conflato. Rand.* The *American* Abutilon, with roundiſh pendulous Fruit, whoſe Seed-Veſſel is like a ſwell'd Bladder.

6. **Abutilon** *Althæoides, flore carneo, fructu globoſo. Hort. Elth.* p. 1. Abutilon with the Appearance of *Althæa*, having a fleſh-colour'd Flower and a globular Fruit.

7. **Abutilon** *Periplocæ acutioris folio, fructu ſtellato. Hort. Elth.* p. 4. Abutilon with a ſharp pointed Periploca Leaf, and a ſtarry Fruit.

8. **Abutilon** *Americanum, folio haſtato, flore amplo purpuro-cæruleo, pediculis longis inſidentibus. Houſt. American* Abutilon, with a Spear-pointed Leaf, and large Purple Flowers with long Footſtalks.

9. **Abutilon** *Americanum, flore albido, fructu e capſulis veſicariis planis conflato, pediculo geniculato. Martyn. Cent.* 1. pl. 33. *American* Abutilon with a whitiſh Flower, a ſmooth ſwelling Seed Veſſel, and a jointed Stalk.

10. **Abutilon** *Americanum, ribeſii foliis, flore carneo, fructu pentagono aſpero. Houſt. American* Abutilon with Currant Leaves, a Fleſh-colour'd Flower, and a rough five-corner'd Fruit.

11. **Abutilon** *Americanum fruteſcens, folio amplo cordato, ſubtus lanuginoſo, floribus amplis luteis. Houſt.* Shrubby *American* Abutilon, with a large heart-ſhaped Leaf, woolly on the under Side, and large yellow Flowers.

12. **Abutilon** *fruticoſum aquaticum, folio cordato ſcabro, flore pallide luteo. Houſt.* Shrubby Aquatick Abutilon, with a rough Heart-ſhaped Leaf, and a pale yellow Flower.

13. **Abutilon** *Americanum, populi folio, leviter ſerrato. Houſt. American* Abutilon, with a Poplar Leaf, ſlightly ſawed on their Edges.

14. **Abutilon** *Americanum fruticoſum, foliis cordatis, floribus parvis purpuraſcentibus. Houſt.* Shrubby *American* Abutilon, with Heart-ſhap'd Leaves, and ſmall purpliſh Flowers.

15. **Abutilon** *Americanum viſcoſum, althææ folio mucronato, flore parvo luteo. Houſt. American* viſcous Abutilon, with pointed Marſh-mallow Leaves, and a ſmall yellow Flower.

16. **Abutilon** *fruticoſum, foliis ſubrotundis ſerratis, floribus albis pentapetalis, ad alas foliorum conglomeratis. Sloan. Cat.* Shrubby *American* Abutilon, with roundiſh ſerrated Leaves, and white Flowers growing in Cluſters from the Wings of the Leaves.

Theſe Plants are moſt of them annual, and require to be raiſed from Seeds every Spring; the firſt and third Sorts may be ſown in the full Ground in *March*, in a light Soil, and an open Expoſure, where they will come up and thrive very well, and perfect their Seeds in *September*. The firſt Sort grows to the Height of three or four Feet, but the third Sort ſpreads on the Ground, ſo ſhould be allow'd Room. Theſe Plants do not bear tranſplanting well, ſo ſhould be ſown where they are to remain; and where they are too cloſe, they ſhould be thinn'd to give them Room to grow. Theſe require no other Culture but to keep them clear from Weeds, which would over-run and deſtroy them.

The ſecond, fourth, fifth, ſeventh, eighth, ninth, and tenth Sorts are alſo annual; but coming from hot Countries, they require to be raiſed on a Hot-bed in the Spring, and muſt be afterwards tranſplanted into Pots, and plunged on a freſh Hot-bed, in order to bring them forward, otherwiſe they will not perfect their Seeds in this Country.

The ſixth Sort grows woody, and will riſe to the Height of eight or ten Feet, the Leaves are very hoary, and the whole Shrub has the Appearance of the *Althæa Frutex*. This Plant may be propagated by ſowing of the Seeds in the Spring, on a moderate Hot-bed, and when the Plants are come up two or three Inches high, they ſhould be tranſplanted each into a ſmall Pot filled with light Earth, and plunged into the Hot-bed, obſerving to water and ſhade them until they have taken new Root, and as the Weather becomes warm, they ſhould be enured to bear the open Air. In Summer theſe Plants may be expoſed to the open Air, in a warm Situation; but in Winter, they muſt be placed in a warm Green-houſe, and will require to be frequently water'd: With this Management the Plants will flower and produce ripe Seeds every Year.

The eleventh, twelfth, thirteenth, and fourteenth Sorts were diſcovered by my late learned Friend Dr. *William Houſtoun*, in the *Spaniſh Weſt-Indies*, from whence he ſent the Seeds, and fair Samples of all the Kinds to *England*. Theſe may all be propagated by Seeds, which muſt be ſown on a Hot-bed early in the *Spring*, and when the Plants are come up about two Inches high, they ſhould be tranſplanted into a freſh Hot-bed, in order to bring them forward, obſerving to water and ſhade them until they have taken Root, after which time they ſhould be conſtantly ſupplied with Water three or four times a Week; and in hot Weather the Glaſſes ſhould be raiſed to admit freſh Air to the Plants, which will greatly ſtrengthen them. When the Plants are grown pretty large, they ſhould be taken up carefully, to preſerve the Earth to their Roots, and each planted into a ſeparate Pot, filled with light rich Earth, and then the Pots ſhould be plunged into a moderate Hot-bed of Tanner's Bark, obſerving to water and ſhade them until they have taken new Root; after which time they ſhould be managed as before. When the Plants are grown too tall to remain under the Glaſſes of the Hot-bed, they ſhould be removed into the Bark-Stove, where they muſt remain all the following *Winter*; but they need not be kept in a very great Heat, a moderate Warmth being much more agreeable to them. The ſecond Year moſt of theſe Plants will flower, provided they are continued in the Stove; for if they are expoſed to the open Air in the *Summer* Seaſon, they will not make any Progreſs, and in a cold *Summer* will be deſtroyed: Therefore it is by far the better Method to keep them conſtantly in the Bark-Stove, and to let them have a large Share of free Air in warm Weather. With this Management moſt of the Sorts will produce Flowers and Seeds in *England*, and may be continued for ſeveral Years.

ACACIA, *Egyptian* Thorn, or Binding Bean Tree. [Ἀκακία of ἀκάζω, Gr. to ſharpen.]

The *Characters* of this Tree are;

It hath ramoſe or branching Leaves; the Flowers adhere cloſely, and form a kind of Sphere or Globe, the Siliqua or Pods are hard and thick, incloſing ſeveral Seeds, which are ſeparated by tranſverſe Diaphragms from each other, and are cloſely ſurrounded with a ſweetiſh pulpy Subſtance.

There is a great Variety of theſe Trees cultivated in the Gardens of *England* and *Holland*, which have been brought from *Africa* and *America*; and are ſome of them hardy enough to endure our Winters abroad (eſpecially ſuch as are Natives of North *America*); others are very tender, and are only to be kept in the warmeſt Stoves.

The *Species* of this Tree are;

1. ACACIA *Americana abruæ foliis triacanthos, ſive ad axillas foliorum ſpina triplici donata, Pluk. Mantiſ.* 1. The American *Acacia* with triple Thorns; or the large-thorn'd *Acacia, commonly called*, The Locuſt Tree in the *Weſt-Indies*.

2. ACACIA *Americana paluſtris abruæ foliis, ſpinis rarioribus.* Water *Acacia* from *Carolina*, with very few Spines.

3. ACACIA *vera. J. B.* The true Egyptian *Acacia*.

4. ACACIA *Indica, foliis ſcorpioides leguminoſæ, ſiliquis fuſcis teretibus reſinoſis. H. L.* The Indian *Acacia*, with taper reſinous Pods.

5. ACACIA *ſimilis Mexiocanæ, ſpinis cornu ſimilibus. Breyn.* The great horn'd *Acacia. Vulgo.*

6. ACACIA *quodammodo accedens, ſive Ceratia & Acacia media Jamaicenſis ſpinoſa, bigeminatis foliis, floſculis flamineis, atronitente, fructu ſiliquis intortis. Pluk. Phyt. Acacia* with branching Leaves and twiſted Pods.

7. ACACIA *arborea, major, ſpinoſa, pinnis quatuor majoribus, ſubrotundis, ſiliquis varie intortis. Sloan. Cat. Plant. Jam.* Large four-leav'd *Acacia*, with twiſted Pods.

8. ACACIA *folio lentiſci, ſempervirens, ſpinis vidua. Hort. Amſt.* Ever-green *Acacia*, without Thorns.

9. ACACIA *non ſpinoſa, flore albo, ſtaminibus longis; foliorum pinnis latiuſculis, glabris & auritis. Houſt. Acacia* without Thorns, having white Flowers, with long Filaments and and broad ſmooth Leaves.

10. ACACIA *humilis, non ſpinoſa, foliis ſubtus incanis, florum ſtaminibus longis rubentibus. Houſt.* Dwarf *Acacia* without Thorns, having red Flowers with long Filaments.

11. ACACIA *Americana, non ſpinoſa, flore purpureo, ſtaminibus longiſſimis, ſiliquis planis villoſis, pinnis foliorum tenuiſſimis. Houſt.* American *Acacia* without Thorns, having Purple Flowers, with very long Filaments, flat hairy Pods, and very narrow Leaves.

12. ACACIA *ſpinoſa, foliorum pinnis tenuiſſimis glabris, floribus globoſis luteis, ſpinis longiſſimis. Houſt.* Prickly *Acacia* with very narrow ſmooth Leaves, round yellow Flowers, and very long Thorns.

13. ACACIA *non ſpinoſa, flore albo, foliorum pinnis latiuſculis glabris, ſiliquis longis planis. Houſt.* White flowering *Acacia* without Thorns, having broad ſmooth Leaves, and long flat Pods.

14. ACACIA *non ſpinoſa, tenuifolia, villoſa, floribus globoſis albis, ſiliquis brevibus hirſutis. Houſt.* Narrow-leav'd hairy *Acacia* without Thorns, having round white Flowers, and ſhort hairy Pods.

15. ACACIA *non ſpinoſa, latiore folio villoſo, floribus globoſis albis, ſiliquis brevibus hirſutis. Houſt.* Broad-leav'd hairy *Acacia*, having round white Flowers, and ſhort hairy Pods.

16. ACACIA *non ſpinoſa, floribus globoſis albis, foliorum pinnis tenuiſſimis glabris; ſiliquis ad ſingula grana tumidis. Houſt. Acacia* without Thorns, having round white Flowers, with very narrow ſmooth Leaves, and jointed Pods.

17. ACACIA *Americana fruteſcens, non aculeata, flore purpureo. Plum.* Shrubby American *Acacia*, without Thorns, and a purple Flower.

18. ACACIA *Americana, flore luteo globoſo, ſpinis exiguis, foliorumque pinnis tenuiſſimis pubeſcentibus. Houſt.* American *Acacia*, with a round yellow Flower, ſmall Thorns with very narrow Leaves, which are hairy.

19. ACACIA *ſpinoſa tenuifolia, floribus ſpicatis luteis, ſiliquis longiſſimis compreſſis flavis. Houſt.* Narrow-leav'd prickly *Acacia*, with ſpiked yellow Flowers, and long compreſſed yellow Pods.

20. ACACIA *ſpinoſa tenuifolia, ſpinis ſingulis cornu bovinum per longitudinem fiſſum referentibus. Houſt.* Prickly narrow-leav'd *Acacia*, with ſingle Thorns reſembling an Ox's Horn, ſplit longitudinally.

21. ACACIA *Americana, faginis foliis, tetraphylla, floſculis ſtaminoſis in ſpicam diſpoſitis. Pluk. Amalth.* Broad four-leav'd *Acacia*, with ſtamineous Flowers, diſpoſed in a Spike.

22. ACACIA *humilis latifolia non ſpinoſa, ſtaminibus florum longiſſimis rubentibus. Houſt.* Dwarf broad-leav'd *Acacia* without Thorns, having long red ſtamineous Flowers.

23. ACACIA *Americana non ſpinoſa latifolia, ſiliquis marginatis, & ad ſingula grana tumidis. Houſt.* Broad-leav'd American *Acacia*, with bordered Pods, which ſwell where each Seed is lodged.

24. ACACIA *ſpinoſa tenuifolia, ſiliquis latis, ſpinis minimis recurvis ſolitariis. Houſt.* Narrow-leav'd thorny *Acacia* with broad Pods, and ſmall crooked Spines, which grow ſingly.

25. ACACIA *non ſpinoſa, ſiliquis latis compreſſis, pinnis foliorum latiuſculis glabris. Acacia* without Thorns, with broad compreſſed Pods, and broad ſmooth Leaves.

26. ACACIA *non ſpinoſa tetraphylla latifolia, ſtaminibus florum longiſſimis rubentibus.* Four-leav'd *Acacia* without Thorns, with broad Leaves, and long ſtamineous red Flowers.

27. ACACIA *non ſpinoſa tenuifolia, ſiliquis varie intortis. Houſt.* Narrow-leav'd *Acacia* without Thorns, and variouſly contorted Pods.

28. ACACIA *Americana tetraphylla & ſpinoſa, floribus globoſis, ſtaminibus florum longis rubentibus.* Four-leav'd prickly *Acacia* with round Flowers having long red Stamina.

The firſt of theſe *Acacia's* Dr. *Plukenet* mentions to have been raiſed in the Garden of the Biſhop of *London* at *Fulham*, about the Year 1698. ſince which Time it hath been raiſed in great Plenty in ſeveral Gardens near *London*, where there are ſeveral very large Trees. This Sort hath produced Flowers in the Phyſick Garden at *Chelſea*, which are very minute, and of an Herbaceous Colour; and in the Year 1729. it produced ripe Fruit in the Gardens of the Biſhop of *London* at *Fulham*. The Seeds of this Tree are frequently brought over from *Virginia* and *Carolina*, by the Name of *Locuſt*, which, I ſuppoſe, is a general Name for moſt Trees which produce Pods, in which are contained a ſweetiſh Pulp ſurrounding the Seeds.

The ſecond Sort is nearly allied to the firſt, but hath very few Thorns; the Shoots are greener, and the Tree is of quicker Growth. The Seeds of this Tree were ſent from *Carolina*, *Anno* 1724. by Mr. *Cateſby*, by the Name of *Water Acacia*, as being an Inhabitant of wet Soils. The Flowers of this Tree have not yet appear'd in *England*, ſo that I can give no Account how this differs in that Particular from the firſt.

The third Sort is the Tree from whence the true *Succus Acaciæ* is taken; which, altho' mention'd as a Native of *Egypt*, yet is alſo found in divers Parts of *America*, from whence the Seeds of this Tree have been ſent into *England*, which have been raiſed in ſeveral Gardens near *London*.

The fourth Sort is the moſt common Kind in *Jamaica*, *Barbadoes*, and the other warm Parts of *America*; and hath, for the Sweetneſs of its Flowers, been diſperſed thro' moſt Parts of *Europe*; which, altho' a Native of the warmer Parts of the *Indies*, yet hath been made familiar to the *Italian Gardens*, and is cultivated in great Plenty in *Portugal* and *Spain*.

The fifth Sort is, at preſent, very rare in *England*, and only to be found in ſome curious Gardens. This Tree produces its Spines by Pairs, which are extreme large and crooked, and of a whitiſh Colour; but I don't remember ever to have ſeen this Flower.

The ſixth Sort was brought from the *Bahama Iſlands* by Mr. *Cateſby*, *Anno* 1726. The Seeds of this Plant (which are flat, and one half, of a beautiful red Colour, the other half a deep black) grow in long twiſted Pods; which, when the Seeds are ripe, open on one Side, and let the Seeds out; which hanging by a ſmall Thread for ſome Time out of the Pods, make a very agreeable Proſpect. The Leaves of this Tree branch out and divide into many Ramifications; the Lobes are roundiſh, and placed in a very regular Order: The Flowers have not as yet appear'd in *England*, but from a Painting done from the Plant in the Country, they ſeem to be very beautiful.

The ſeventh Sort was brought from *Jamaica*, and is growing in the *Phyſick Garden* at *Chelſea*: This hath four large Lobes to each Leaf; the Spines are ſhort, ſtiff, and crooked, and the Seeds grow in twiſted Pods. This Plant is well deſcribed in Sir *Hans Sloane*'s *Natural Hiſtory of Jamaica*.

The eighth Sort was brought firſt into *England* from *Holland*, and is probably a Native of *Africa*. This Plant is an Ever-green, and without Spines, which is peculiar to this Sort alone. The Flowers of this Tree I have never yet ſeen.

The Sorts from the ninth to the ſixteenth are tender, and muſt be placed in Stoves in the Winter, and in Summer muſt be but a ſhort time expoſed to the open Air, and muſt have a warm Situation.

Theſe Trees are all propagated by ſowing their Seeds on a Hot-bed in the Spring of the Year, which will in a ſhort time appear above Ground, when you ſhould prepare another freſh Hot-bed, which if intended for ſuch Sorts as are very tender, ſhould be pretty warm; but if for ſuch as are brought from the Northern Parts of *America*, ſhould be of a very moderate Heat; then you ſhould be provided with a Quantity of ſmall Half-penny Pots, which ſhould be fill'd with freſh light ſandy Earth; theſe ſhould be plung'd into the Hot-bed, and as ſoon as the Earth in the Pots is warm, which will be in about twenty four Hours, you ſhould take up the young Plants carefully out of the firſt Hot-bed, planting a ſingle one in the Middle of each of theſe Pots, giving them a gentle Watering to ſettle the Earth to their Roots, and ſcreening them with Mats over the Glaſſes, from the Heat of the Sun, until they have taken Root; after which time you muſt give them Air, by raiſing the Glaſſes, in proportion to the Heat of the Weather, or to the Conſtitution of the Plants.

The firſt and ſecond Sort being very hardy, may have a greater Proportion of Air, and by *Midſummer* ſhould have the Glaſſes intirely taken off, that they may be hardened to endure the open Air by degrees: Theſe, the firſt and ſecond Winter, ſhould be ſhelter'd in a common Hot-bed Frame, until they are grown woody; after which Time (in the Spring of the Year) they may be turn'd out of the Pots into the open Ground, where they are intended to remain; which ſhould be in Wilderneſs Quarters; or Clumps of Trees, where they may be ſhelter'd from the Fury of violent Winds, otherwiſe they will be very ſubject to be ſplit thereby.

When theſe Trees have ariſen to the Height of 8 or 10 Feet, they will then make very ſtrong and vigorous Shoots; which ſhould be annually ſhorten'd, that the Heads of the Trees may be cloſer, and their Branches by this means will be much leſs liable to break with Winds, than when they are permitted to remain at full Length, and the Trees will be much the handſomer.

Theſe Plants delight in a looſe Soil, rather moiſt than dry, in which they will ſhoot very vigorouſly.

The fourth, fifth, and eighth Sorts are tenderer, and ſhould be kept in the Hot-beds till *July*, when they may be expoſed to the Air by degrees, tho' the Glaſſes ſhould not be quite removed from them the firſt Year: Theſe muſt be ſet in a Stove the firſt and ſecond Winters, while young, as being then pretty tender; but when they are grown woody, will endure in a good Green-houſe very well, and may be expoſed in Summer-time, with Oranges, Myrtles, *&c.* Theſe, if kept in a Green-houſe, will require but little Water in Winter, eſpecially thoſe which ſhed their Leaves, as being at that Seaſon incapable of diſcharging a Redundancy of Moiſture; their Leaves, which were the greateſt Inſtruments in throwing off ſuperfluous Moiſture by Perſpiration, being gone, the whole Tree ſeems to remain for a certain Time in a State of Reſt.

The third, ſixth, and ſeventh Sorts are very tender, (eſpecially while young) and therefore ſhould have a Hot-bed of *Tanners Bark*; and as they increaſe in Bulk, ſhould be ſhifted into bigger Pots; the Earth for theſe ſhould be a little lighter, and more inclined to a Sand than for the other Sorts, but never give them too big Pots, which is full as bad to theſe as to *Orange Trees*, neither give them too much Water, eſpecially in Winter: The third Sort being the hardieſt of the three, will, when grown to be woody, ſtand in a common Stove amongſt *Guava's*, *Viburnums*, &c. which ſhould be kept to the Point of temperate Heat in Winter; and in the Summer-time, in warm Weather, may enjoy the free open Air: But the ſixth and ſeventh Sorts muſt have a Bark Stove in Winter, nor ſhould they be expoſed to the open Air in Summer, at leaſt for four or five Years, until they are grown very woody, for they are very tender, and with great Difficulty preſerved in this Climate: The Stove in which theſe ſhould be placed in Winter, muſt be kept up to about ten Degrees of Heat above the temperate Point, as mark'd on Mr. *Fowler's Botanical Thermometers*: Theſe ſhould have very little Water in Winter, but in the Summer-time will require frequent Refreſhings, tho' at that Seaſon it ſhould not be given them in great Quantities at one time. The ſixth Sort is an Ever-green, but the ſeventh ſheds its Leaves juſt before the new ones come on; ſo that it is naked of Leaves about a Month or ſix Weeks in the Spring of the Year; which hath occaſion'd ſome People to throw them away as dead, when, if they had let them remain, they would have come out freſh again. This I thought proper to mention, in order to caution People not to be too haſty in throwing out Trees for dead, but preſerve them thro' the ſucceeding Summer, to ſee if there is any Life left in them; for I have known ſeveral Plants, which, after having been given over by unſkilful Perſons for dead, have, the *July* following, ſhot out vigorouſly again; and others which have been deſtroyed to the Surface of the Earth, have riſen again from the Root.

The firſt and ſixth Sorts are figured in Dr. *Plukenet's Phytographia*. The third Sort is figured in moſt of the old Botanick Writers, as *John Bauhin*, *Dodonæus*, *Parkinſon*, &c. The Pods of this Kind are jointed and compreſſed into a ſort of Iſthmus between every Seed. The fourth Sort is extremely well figured, and deſcribed in the *Hortus Farneſianus* by *Aldinus*. The fifth Sort is very well figured, and deſcribed in the *Hortus Amſtelodamenſis*. The ſeventh Sort is figured in *Piſo's* Hiſtory of *Braſil*; but the ſecond Sort is new, and not figured in any Botanick Books.

The laſt twenty Sorts of *Acacia* were collected by the late Dr. *Houſtoun*, in *Jamaica*, at *Carthagena*, and *Le Vera Cruz*, who ſent the Seeds and Specimens to *England*, where many of the Kinds are now growing. Theſe Plants are propagated by Seeds, which muſt be procured from the Countries where they naturally grow; for they do not produce Seeds in *Europe*. In the bringing over of the Seeds, great care ſhould be taken to preſerve them from Inſects, which do generally eat into the Pods, and alſo eat up the Subſtance of the Seeds, leaving only the outer Covering: Theſe Inſects are very ſmall, ſo as often to eſcape the Sight; but if you find any Pods to have Holes in them, you may then conclude there are Inſects amongſt them, ſo that the ſooner you take out the Seeds, the more ſurely you will preſerve them; but you ſhould put them into freſh Papers, and throw away thoſe in which the Pods had been, leſt ſome of the Inſects ſhould be left therein.

The Seeds of all theſe Sorts ſhould be ſown on a Hot-bed early in the *Spring*; and when the Plants are come up, they ſhould be tranſplanted into ſmall Pots filled with light freſh Earth, and plunged into a Hot-bed of Tanners Bark, obſerving to water and ſhade them until they have taken new Root, after which time, they muſt be treated in the Manner directed for the *Egyptian Acacia*. Theſe Plants muſt be conſtantly kept in the Bark-Stove, otherwiſe they will make very little Progreſs, eſpecially while they are young. In the *Summer* Seaſon theſe Plants ſhould have a large Share of freſh Air, and muſt be frequently refreſhed with Water, and in *Winter*, the Stove in which they are placed, ſhould be kept to a temperate Degree of Heat; with this Management theſe Plants will thrive extremely well, and moſt of them will produce Flowers in two or three Years from the Time of their being ſown.

ACACIA Germanorum: *Vide* Prunus Sylveſtris.
ACACIA Virginiana: *Vide* Pſeudoacacia.

ACAJOU, *or* Cajou. The Caſhew Nut.

The *Characters* are;

The Cup of the Flower (which is produced at the Extremity of a Foot-ſtalk) is oblong, and quinquifid; the Flower conſiſts of one Leaf, which is divided into five long narrow Segments; in the Bottom of the Calyx is the Ovary, which becomes a ſoft Pear-ſhap'd Fruit, upon the Apex of which grows a Veſſel, in which is contained one Kidney-ſhap'd Seed.

There is but one *Species* of this Plant yet known, which is,

ACAJOU; *Thev. Franc. Antarct.* The Caſhew Nut.

This Tree is very common in many Parts of *America*, particularly in *Jamaica* and *Barbadoes*, where it grows to be a very large Tree, but with us in *England* (notwithſtanding all the Care it can poſſibly have) will rarely ſtand thro' our Winters; or if it is by Art preſerved, in very warm Stoves, yet it is ſo very ſlow of Growth, eſpecially after the firſt Year, as ſcarcely to be diſcern'd in its Progreſs.

The Seeds of this Tree, if ſown in a good Hot-bed in the Spring of the Year, will in a ſhort time appear above Ground, in ſo ſtrong a manner that any one, who hath not been converſant with this Plant, would imagine it to be of very quick Growth; for I have known theſe Plants in two Months from the time of ſowing their Seeds, above ſix Inches in Height, and very ſtrong; which in about two Months time more have been at a Stand, from which time they have ſcarcely advanced two Inches in a Year, with all the Art and Skill which could be uſed to them; nor have I ever ſeen a Plant of this Kind above two Feet high, tho' I have had ſome of them that have been three or four Years old: They are alſo in their own Country of very ſlow Growth, rarely producing either Flowers or Fruits, until they are 15 or 16 Years old from Seeds, ſo that the Inhabitants of the *Weſt Indies* plant them from large Branches taken from the old Trees, which with them take Root very well, and in two Years time produce Fruits.

The Plants of this Kind which are raiſed in *England*, ſhould be planted in ſmall Pots fill'd with freſh, light, rich Earth, and muſt be plung'd into a Hot-bed of *Tanners Bark*, and often refreſh'd with Water: theſe ſhould be kept, in Winter, in a Bark Stove, amongſt the tendereſt Exotick Trees, and ſhould not be expoſed to the open Air even in the hotteſt Seaſon.

One Plant of this Kind flower'd in the Garden of Sir *Charles Wager*, at *Parſons-Green* near *Fulham*, tho' not above two

Years old, but it ſoon after periſh'd without producing any Fruit.

The Seeds of this Tree are the *Anacardium Occidentale*, or Weſtern Anacardium of the Shops: The outer Covering of this Seed is very full of a ſharp, acrid Oil, which will give great Pain to the Mouth, if bitten or chew'd; if burnt off by a Candle, it will emit a Flame of various Colours: The Kernel within is very ſweet, and eſteem'd wholſome.

ACANACEOUS Plants, [of Ἀκάζω, *Gr.* or *Acuo*, *Lat.* I ſharpen; on account of the Prickles they are beſet withal] are ſuch as are of the Thiſtle Kind, which have Heads, and are prickly.

ACANTHUS, [Ἄκανθος, ſo call'd, as ſome ſay, of ἄκανθα, a Thorn, or as others ſay, of the Youth *Acanthus*, whom the Poets fable to be metamorphos'd into the Flower of this Herb] This is call'd *Brancha Urſina*, or *Bear's-breech.*

The *Characters* of this Plant are;

The Leaves are ſomewhat like thoſe of the Thiſtle; the Flowers are labiated; the under Lip of the Flower is divided into three Segments, which in the Beginning is curl'd up in Form of a ſhort Tube; in the Place of the upper Lip are produced the Stamina (or Seeds) which ſupport the Pointals: the Cup of the Flower is compoſed of Leaves which are prickly; the upper Part of which is bent over like an Arch, and ſupplies the Defect of the upper Lip of the Flower: The Fruit is of an Oval Form, which is divided in the Middle into two Cells, each containing one ſingle ſmooth Seed.

There are five *Species* of this Plant to be found in the Gardens of the Curious; *viz.*

1. Acanthus, *ſativus, vel mollis Virgilii. C. B.* The ſmooth-leav'd Garden Bear's-breech.
2. Acanthus, *aculeatus. C. B.* The prickly Bear's-breech.
3. Acanthus, *rarioribus & brevioribus aculeis munitus. Tourn.* The middle Bear's-breech, with ſhort Spines.
4. Acanthus, *Luſitanicus, ampliſſimo folio lucido.* The *Portugal* Bear's-breech, with large ſhining Leaves.
5. Acanthus *orientalis humillimus, foliis pinnatis aculeatis. Tourn. Cor.* Dwarf Eaſtern Bear's-breech, with prickly winged Leaves.

The firſt Sort is what is uſed in Medicine, and is ſuppoſed to be the *Mollis Acanthus* of *Virgil.* The Leaves of this Plant are cut upon the Capitals of the *Corinthian* Pillars, and were formerly in great Eſteem with the *Romans.*

They are all very pretty Varieties, and fit for large Gardens, but ſhould have a warm Situation, and a dry Soil. They are eaſily propagated, by parting the Roots in *February* or *March*, or by Seeds ſown at the ſame time. The ſecond and third Sorts are apt to creep at the Root, therefore ſhould have Room, and muſt not be planted amongſt other Flowers, leſt they overgrow and deſtroy them.

The fifth Sort was diſcovered by Dr. *Tournefort* in the *Levant*, who ſent it to the *Royal Garden* at *Paris.* This may be propagated by Seeds, which ſhould be ſown on a Bed of light freſh Earth in the *Spring* of the Year, and when the Plants are come up, they ſhould be carefully weeded, and in very dry Weather they ſhould be watered, which will greatly promote the Growth of the Plants. In this Bed they may remain until the following *Spring*, when they ſhould be carefully taken up and tranſplanted, where they are deſigned to remain, which ſhould be in a warm Situation, and on a dry freſh Soil. Theſe Plants ſhould be allowed a great Share of Room, for they are very apt to ſpread far, and their Leaves do grow to a great Size, when the Plants are ſtrong, ſo that if any other Plants ſtand near them, they will be in danger of ſuffering by being over-ſpread.

It has been much diſputed by the Learned, whether the common Sort of *Acanthus* is the Plant which *Virgil* mentioned under that Name, but this is not eaſy to be reconciled; for, according to *Pliny*, the *Acanthus* ſhould be a tonſile Plant, and proper to cut into Figures, and *Virgil* makes it an *Ever-green*, a *Berry-bearing Plant*, and a *Climber*; neither of which Properties belong to our *Acanthus*, but the Deſcription which *Dioſcorides* has given of the *Acanthus* agrees very well with our common *Bear's-breech*; and from the remains of ſome antient Buildings at *Rome*, which have the Figure of the *Acanthus* cut on the *Capitals* of the Pillars, which are yet intire, there is a good Reſemblance to the Leaves of the common *Acanthus.*

ACAULIS, or ACAULOS; of *a* Neg. and *Caulis*, [a Stalk or Stem] *i. e*, without Stalk: A Plant is ſaid to be *Acaulis*, or without Stalk, whoſe Flower reſts on the Ground.

ACER, The Maple-Tree, [ſo call'd, according to *Voſſius*, of *Acris*, *L.* becauſe of the very great Hardneſs of the Wood.]

The *Characters* are;

It hath jagged, or angular Leaves; the Seeds grow two together in hard wing'd Veſſels.

There are in *England* eight or nine *Species* of this Tree; *viz.*

1. Acer *majus, multis falſo Platanus. J. B.* The greater Maple, *falſely call'd*, The Sycamore Tree.
2. Acer *majus, foliis eleganter variegatis. Hort. Edin.* The greater Maple, with ſtrip'd Leaves, *commonly call'd*, The ſtrip'd Sycamore.
3. Acer *campeſtre & minus. C. B.* The common, or leſſer Maple.
4. Acer *Virginianum, folio majore, ſubtus argenteo, ſupra viridi ſplendente. Pluk. Phyt.* The *Virginian* flowering Maple.
5. Acer *Americanum, folio majore ſubtus argenteo, ſupra viridi ſplendente, floribus multis coccineis.* The *American* flowering Maple, with larger Bunches of ſcarlet Flowers.
6. Acer *maximum, foliis trifidis vel quinquifidis Virginianum. Pluk. Phyt.* The *Virginian* Aſh-leav'd Maple.
7. Acer *Platanoides. Munt.* The *Norway* Maple, with Plane-tree Leaves.
8. Acer *Platanoides, foliis eleganter variegatis.* The ſtrip'd *Norway* Maple.
9. Acer *trifolium. C. B. P.* Maple Tree with a trifoliated Leaf.

Theſe Trees are eaſily propagated, by ſowing the Seeds, ſoon after they are ripe, in an open Bed of common Earth, covering them about half an Inch thick with light ſandy Earth; the Spring following they will appear above Ground, and if kept clear from Weeds, will grow above a Foot high the firſt Summer: The *Michaelmas* following (if they are thick in the Seed-bed) you may take out a Part of them and tranſplant into a Nurſery, in Rows at three Feet diſtance, and two Feet aſunder in the Rows; in which Place they may remain three or four Years, when they will be large enough to plant out for good.

The firſt Sort is very proper to make Plantations near the Sea, or to ſhelter ſuch Plantations of Trees as are too nearly ſituated thereto: This Tree thrives, and reſiſts the Spray which is uſually blown from the Sea, better than moſt other Trees do. The variegated Sort is alſo raiſed from Seeds of the ſame Kind: Moſt of the Plants ſo raiſed, will be as finely ſtrip'd as the old Plant from whence the Seeds were taken, which is not common to many other variegated Plants.

The common Maple is too well known to need any particular Account, it being a very common Tree in Hedge-rows in moſt Parts of *England*; it is raiſed in the ſame Manner with the former.

The *Virginian* flowering Maple was raiſed from Seeds, which were brought from *Virginia* many Years ſince by Mr. *John Tradeſcant*, in his Garden at *South Lambeth* near *Vaux-hall*, and ſince, in the Gardens of the Biſhop of *London* at *Fulham*, where it has flower'd for ſeveral Years, and produces ripe Seeds, from whence ſeveral Trees have been raiſed: It may be alſo propagated by laying down the young Branches early in the Spring, giving them a little Slit at a Joint, by which Means they will have taken ſufficient Root by that time Twelvemonths, to be tranſplanted out: They require a Situation a little defended from the North-Eaſt Winds, eſpecially while young. This Tree commonly flowers in the Beginning of *April*, and the Seeds are ripe in five or ſix Weeks after; at which Time they ſhould be ſow'd; for they are very apt to periſh, if kept long out of the Ground.

The other flowering Maple was ſent from *America* to Sir *Charles Wager*, and flouriſhes in his curious Garden at *Parſons-Green* near *Fulham*: The Flowers of this Kind come out in very large Cluſters, and ſurround the younger Branches, ſo as to appear at a ſmall Diſtance covered therewith. This Tree is at preſent very rare in *Europe*; but as it produces ripe Seeds in *England*, ſo it is to be hoped it will in Time be more common in the Gardens of the Curious.

The Aſh-leav'd Maple is a very ſtrong ſhooting Tree, and is in *Virginia* one of the largeſt Trees of this Kind: It muſt be planted in Places not too much expoſed to violent Winds, it being ſubject to ſplit therewith. This Tree ripens Seeds very well in *England*, by which means it is eaſily propagated, or by laying down the Branches (as directed for the flowering Maple.)

The *Norway* Maple grows with us to a very large Size, equalling the greater Maple for Bulk, and I believe will anſwer the ſame Purpoſes, for ſheltering Plantations near the Sea, and is by far the handſomer Tree near an Habitation; for the greater Maple is very ſubject to exude a ſweet clammy Juice from the Pores of the Leaves, which lodges upon the Surfaces thereof, and thereby intices vaſt Quantities of Inſects, which eat the Leaves full of Holes, and render them very unſightly.

The *Norway* Maple has a milky ſharp Juice, ſo that few Inſects care to prey thereon; by which means the Leaves are ſeldom eat or defaced: This Tree is alſo raiſed by Seeds, of which it affords great Quantities, which riſe and grow equally as well as the common Sort.

The variegated Kind is propagated by inoculating a Bud of the ſtrip'd Kind into one of the plain Sort, tho' I am not at preſent ſure, whether it will take upon any other Sort of Maple, not having made the Experiment; but I believe it can ſcarce fail: Moſt, if not all the other Sorts of Maples, take very well upon each other.

The ninth Sort of Maple grows plentifully about *Montpelier*, and other Places in the *South* of *France*, where it riſes to the Height of our common Maple; but in *England* it is very rare at preſent, and only to be found in ſome curious Botanick Gardens. This Tree may be propagated from Seeds, in the ſame manner as our common Maple; but the Seeds ſhould be ſown in Autumn, ſoon after they are ripe, otherwiſe they ſeldom grow, which is the Reaſon why this Tree is ſo ſcarce in *England*; for there are no Trees which have yet produced Seeds here, and the Seeds will not retain their growing Quality ſo as to bear tranſporting hither, unleſs they are put into Earth or Sand, by which Method they might be brought over very ſafe.

There is another Sort of Maple, which is very common in *Virginia*, and is known by the Name of the *Sugar Maple*; from which Tree the Inhabitants of that Country make a very good ſort of Sugar, and in large Quantities: but this Tree is at preſent very rare in *Europe*; tho' I am of Opinion, that the People make Sugar from more than one Sort of Maple; Mr. *Ray* and Dr. *Liſter* prepared a tolerable good Sort of Sugar from our greater Maple, by tapping ſome of the Trees in their bleeding Seaſon; and I have obſerved, upon cutting off a Branch of the Aſh-leav'd Maple in *February*, a great Quantity of a very ſweet Juice hath flow'd out for ſeveral Days together.

The Timber of the common Maple is far ſuperior to the *Beech* for all Uſes of the Turner, particularly *Diſhes*, *Cups*, *Trenchers*, and *Bowls*; and when it abounds with Knots (as it very often doth) it is highly eſteem'd by the *Joiners* for Inlayings, *&c.* and alſo, for the Lightneſs of the Wood, is often employ'd by thoſe that make *Muſical* Inſtruments; and for the Whiteneſs of its Wood, is in great Requeſt for *Tables*, &c.

ACETOSA, [of *Acetoſus*, eager, ſour, *L.*] Sorrel, ſo call'd of the *Anglo-Saxon* ꞅuꞃ, ſour.

The *Characters* are;

This Plant agrees with the Dock *in all its Characters, and only differs in having an acid Taſte.*

There are ſeveral Varieties of this Plant, which are cultivated by the Curious in Botany, but there are not above two or three Sorts which are worthy propagating for Uſe; the reſt are only fit for the Curious to amuſe with.

1. Acetosa *pratenſis. C. B.* The Common or Meadow Sorrel.

2. Acetosa *Muſcovitica, ſterilis. M. H.* The Northern barren Sorrel.

3. Acetosa *rotundifolia, hortenſis. C. B.* The Round-leav'd or *French* Sorrel.

4. Acetosa *foliis criſpis. C. B. P.* Sorrel with curled Leaves.

5. Acetosa *montana maxima. C. B. P.* Greateſt Mountain Sorrel.

6. Acetosa *Pyrenaica, anguſtiſſimo & longiſſimo folio. Schol. Bot.* *Pyrenean* Sorrel with very long narrow Leaves.

7. Acetosa *montana, lato ari rotundo folio. Bocc. Muſ.* Mountain Sorrel with a broad Arum Leaf.

8. Acetosa *montana pumila, fagopyri folio. Bocc. Muſ.* Dwarf Mountain Sorrel with a Buck-wheat Leaf.

9. Acetosa *tuberoſa radice, C. B. P.* Sorrel with a tuberoſe Root.

10. Acetosa *calthæ folio, peregrina. C. B. P.* Foreign Sorrel with a Marygold Leaf.

11. Acetosa *lucida, folio atriplicis. H. R. Par.* Shining Sorrel with Orach Leaves.

12. Acetosa *major Italica, ſemine rotundiore & glomerato. H. R. Par.* Greater *Italian* Sorrel, with a round glomerated Seed.

13. Acetosa *arvenſis lanceolata. C. B. P.* 124. Sheep's Sorrel.

14. Acetosa *lanceolata anguſtifolia elatior. Mor. Hiſt.* Taller narrow-leav'd Spear-pointed Sorrel.

15. Acetosa *ocymi folio, Neapolitana. C. B. P.* *Neapolitan* Sorrel with a Baſil Leaf.

16. Acetosa *Americana, foliis longiſſimis pediculis donatis. C. B. P.* *American* Sorrel with Leaves growing on long Pedicles.

17. Acetosa *rotundifolia repens Eboracenſis, folio in medio deliquium patiente. Mor. Hiſt.* Creeping round-leav'd Sorrel of the North.

18. Acetosa *arboreſcens, ſubrotundo folio, ex Inſulis Fortunatis. Pluk. Almag.* Shrubby Sorrel with a round Leaf, from the Fortunate Iſlands.

The firſt of theſe Sorts, tho' but ſmall in the Fields, yet when ſown in Gardens, will produce large fair Leaves, and is the ſame Sort which is commonly cultivated in Gardens. It muſt be ſown early in the Spring, in a ſhady moiſt Border; and if the Plants are afterward planted out in another ſhady Border, four or ſix Inches ſquare, it will produce larger Leaves, and continue longer. This is the common Sorrel uſed in Medicine; but the Northern barren Soil is preferr'd to it in the Kitchen-Garden, it rarely running to Seed, but is increaſed by parting the Roots either in Spring or Autumn, and is fit for Uſe all the Year round.

The Round-leav'd (or *French*) Sorrel, is the moſt grateful Acid, and is preferr'd to the firſt two Sorts for Kitchen Uſe; it is alſo a medicinal Plant, and ſhould not be wanting in any good Garden: It is a great Runner at the Root, by which means it is eaſily propagated, and muſt be planted at a large Diſtance a Foot ſquare at leaſt; it will agree better with an open Situation than the firſt two Sorts.

The fourth Sort of Sorrel is a Variety from the common Sort, which often ariſes from the ſame Seeds, as doth alſo that with white Flowers, ſo that they do not deſerve the Notice which the Writers on Botany have taken of them.

The fifth, ſixth, ſeventh, eighth, ninth, tenth, eleventh, and twelfth Sorts are all of them very hardy Plants, and may be propagated by Seeds, in the ſame manner as the common Sort, with this Difference only, of allowing the large Sorts more room; for the ſixth and ſeventh Sorts grow very large, and therefore require to be left a Foot aſunder, or more. The Roots abide ſeveral Years, and may be parted at *Michaelmas* to propagate their Kinds; tho' they all ſucceed much better by Seeds, which they uſually perfect in this Country.

The thirteenth and fourteenth Sorts grow wild on dry Banks, and on the Sides of Gravel Pits, in diverſe Parts of *England*, and are rarely admitted to have Place in a Garden. Theſe multiply exceedingly by their Roots, which creep very far under Ground, ſo that they ſhould not be ſuffered to grow near other Plants. The thirteenth Sort is placed in the Catalogue of Simples, in the College Diſpenſatory, but, I believe, is ſeldom ordered in Medicine.

The fifteenth and ſixteenth Sorts are annual, and are rarely cultivated, except in Botanick Gardens, for the ſake of Variety; theſe may be propagated by ſowing of their Seed on a Bed of light Earth in *March*, and when the Plants are come up, they ſhould be conſtantly kept clean from Weeds, and where they are too cloſe to each other, they ſhould be thinned, but they do not bear tranſplanting well, therefore they ſhould always be ſown where they are deſigned to remain. In *June* theſe Plants will flower, and their Seeds will ripen in *Auguſt*.

The ſeventeenth Sort grows wild in *Yorkſhire*, and ſeveral other Northern Counties of *England* and *Scotland*, from whence it is often procured for the ſake of Variety, but it doth not thrive in the Southern Parts well; it ſhould have a ſhady Situation, and a moiſt ſtrong Soil.

The eighteenth Sort will grow to the Height of twelve or fourteen Feet and become woody, ſo as to have the Appearance of a Tree. This is preſerved in Green-houſes in Winter, by Perſons who are curious in collecting Exotick Plants. It may be eaſily propagated by planting Cuttings in a Bed of light Earth, during any of the Summer Months, obſerving to water and ſhade them until they have taken Root, when they ſhould be taken up and planted in Pots filled with freſh Earth, and placed in a ſhady Situation, until they have taken new Root, after which Time they may be placed amongſt *Myrtles*, *Geraniums*, and other hardy Exotick Plants, till *October*, when they ſhould be removed into the Green-houſe, where they ſhould be placed to have as much free Air as poſſible in mild Weather, for otherwiſe they will become very weak and unſightly.

ACETOSELLA: *Vide* Oxys.

ACHILLÆA: *i. e.* Millefolium.

ACINOS: Stone *or* Wild Baſil.

The *Characters* are;

It hath Leaves like thoſe of the leſſer Baſil; *the Cup of the Flower is oblong and furrow'd; the Flowers are produced in Bunches, on the Top of little Footſtalks, which ariſe from between the Footſtalk of the Leaf, and the Stalk of the Plants, in which it differs from* Serpyllum.

The *Species* are;

1. Acinos *multis. J. B.* Wild Baſil.
2. Acini *pulchra ſpecies. J. B.* Broad-leav'd *Auſtrian* Wild Baſil.

The firſt of theſe Plants is very common on dry arable Land in many Parts of *England*, but eſpecially on gravelly or chalky Hills: It is an annual Plant, ſowing itſelf, and riſing again early in the Spring: This is not cultivated in Gardens, nor doth it care to grow on a good Soil; but it may be propagated in a dry poor Soil, by ſowing the Seeds ſo ſoon as they are ripe. This Plant hath been brought to the Markets by the Herb-women for the Mountain Poley.

The ſecond Sort is preſerved in curious Botanick Gardens, but is a Plant of no great Beauty or Uſe.

ACINUS, or ACINI, by good Authors is uſed not for the Grape-ſtone, but the Grape itſelf, as *Columella, cum expreſſeris Vinacea, quæ acinis celantur:* It is commonly uſed for thoſe ſmall Grains growing in Bunches, after the manner of Grapes, as the *Sambucus, Liguſtrum*, &c.

ACONITUM, Wolf's-bane; [Ἀκόνιτον, which ſome derive of ἀκόνη, a Well-ſtone or Rock, becauſe it grows on bare rocky or ſtony Places; others of ἀ and κόνις, Duſt, becauſe it grows without Earth; others of ἄκων ἀκὴ, a Dart, becauſe the *Barbarians* uſed to daub their Darts therewith; others of ἀκωνίζωμαι, to accelerate, becauſe it haſtens Death.] The *Engliſh* call it Wolf's-bane, of the *Anglo-Saxon* Ƿulfeſ-bana.

The *Characters* are;

It hath circumſcrib'd roundiſh divided Leaves; the Flowers conſiſt of four Leaves, which are ſhaped like a Monk's Hood: Each of theſe Flowers are ſucceeded by three or more Pods, which contain ſeveral rough Seeds: The moſt Part of theſe Species are deadly Poiſon.

The *Species* are;

1. Aconitum *lycoctonum, luteum. C. B.* The yellow poiſonous Wolf's-bane.
2. Aconitum *luteum majus, ampliore caule, amplioribuſque foliis. Dod.* The largeſt yellow Wolf's-bane.
3. Aconitum *cæruleum, ſive napellus.* II. *C. B.* The large blue Wolf's-bane, *or* Monk's-hood.
4. Aconitum *ſalutiferum, ſive anthora. C. B.* The wholſome Wolf's-bane.
5. Aconitum *pyramidale multiflorum. H. R. Par.* Large blue pyramidal Wolf's-bane, *or* Monk's-hood.
6. Aconitum *lycoctonum, humili caule, ac minoribus foliis. Dod.* Dwarf Wolf's-bane with leſſer Leaves.
7. Aconitum *Pyrenaicum, ampliore folio tenuius laciniato. Tourn.* Wolf's-bane of the *Pyrenean* Mountains, with larger Leaves, cut into narrow Segments.
8. Aconitum *cæruleum, napelli flore. C. B. P.* 283. Autumnal Wolf's-bane with a blue Flower.
9. Aconitum *coma inflexa, foliis anguſtioribus. C. B. P.* 283. Narrow-leav'd Wolf's-bane with inflex'd Heads.
10. Aconitum *coma inflexa, foliis latioribus. Tourn.* Broad-leav'd Wolf's-bane, with inflex'd Heads.
11. Aconitum *inflexa coma, maximum. C. B. P.* Wolf's-bane, with the largeſt inflex'd Heads.
12. Aconitum *ſeu napellus* 1. *flore roſeo. C. B. P.* Wolf's-bane, with a Roſe-colour'd Flower.
13. Aconitum *ſeu napellus* 1. *flore albo. C. B. P.* Wolfſ-bane, with a white Flower.
14. Aconitum *ſeu napellus* 1. *flore ex cæruleo & albo variegato. C. B. P.* Wolf's-bane with a Flower variegated from blue to white.
15. Aconitum *violaceum ſeu napellus* 2. *C. B. P.* Wolf's-bane, with a Violet-colour'd Flower.
16. Aconitum *purpureum ſeu napellus* 3. *C. B. P.* Wolf's-bane, with a Purple Flower.
17. Aconitum *cæruleum minus, ſive napellus minor. C. B. P.* Leſſer blue Aconite or Wolf's-bane.
18. Aconitum *cæruleo-purpureum, flore maximo, ſive napellus* 4. *C. B. P.* Wolf's-bane, with a very large Purple-blue Flower.
19. Aconitum *lycoctonum orientale, flore magno albo. T. Cor.* Eaſtern Wolf's-bane, with a large white Flower.

Moſt of theſe Kinds of *Wolfſbane* are Natives of the *Alps* or *Pyrenean* Mountains, where (it is reported) the Huntſmen who hunt the Wolves, dip their Arrows into the Juice of theſe Plants, which renders the Wounds given with theſe Arrows, mortal. They are moſt of them too noxious to have a Place in Gardens which are much frequented by Children, tho' the fifth Sort is too commonly found in old Gardens, and the Flowers are frequently brought into the *London* Markets, and mixed with other Flowers to adorn Halls, &c. but we have had many Inſtances of Perſons who have loſt their Lives, and of others who have with great Difficulty been recovered, after having eaten of this Herb in Sallets, which by Miſtake has been put into Sallets inſtead of Celery, by very ignorant People. A late Inſtance of this hath been publiſhed in the *Philoſophical Tranſactions*, where there is an Account of an unſkilful Perſon gathering ſome Roots of this Wolfſbane (early in the Spring, when the Plant was newly riſen above Ground) inſtead of *Celery:* and putting of them into a Sallet, two Perſons were poiſoned therewith; one of whom was with great Difficulty ſaved.

The fifth Sort of Wolf's-bane is very common in almoſt all old Gardens, and is uſually known by the Name of Monk's-hood, the Flower reſembling a Frier's Cowl, from whence it had that Name: the Flowers of this Kind are commonly brought to Market in *May*, to furniſh Flower-pots for Chimnies. The Roots of this Plant increaſe abundantly, ſoon over-running a large Piece of Ground, therefore ſhould be confined in ſome abject Part of the Garden, or planted under Trees, it being very hardy, and growing in almoſt every Soil or Situation.

All theſe Kinds of Wolfſbane are great Ornaments to a large Garden, and many of them will thrive in the greateſt Shade, and on the pooreſt Soil, where few other Plants will grow, eſpecially the fifth, eighth, twelfth, fifteenth, ſixteenth, and ſeventeenth Sorts, which are extremely hardy, and multiply greatly by the Root, ſo that a few Plants of each Sort will, in a few Years, produce a great Stock. The beſt Time to tranſplant theſe Roots, is at *Michaelmas*, where the Roots remain in an unactive State; for ſoon after that Time, they begin to put out new Roots, and early in the Spring the Plants will appear above Ground; when it will be too late to tranſplant them; for although they will often grow if removed at that Seaſon, yet they rarely flower the ſame Year, and will make very little Increaſe at the Root.

Some of the Sorts with blue Flowers will grow to the Height of three or four Feet, but thoſe with yellow Flowers uſually grow much higher, and the Eaſtern Kind with white Flowers, I have ſeen upward of ſix Feet high; but this Sort is very rare in *Europe*, and only to be found in ſome curious Gardens at preſent.

The fifth Sort commonly begins to flower in *April*, and continues thro' *May*, and this is ſucceeded by ſome of the other Sorts, ſo that there is a continual Succeſſion of them, until *Auguſt*, and in a cool Seaſon ſometimes later.

The yellow Sorts are leſs common, and are only preſerved in the Gardens of the Curious; they flower in *June* and *July*, and are increaſed by parting the Roots in *Autumn*, but muſt have a more open Expoſure than the Blue.

The wholſome Kind is rarely to be met with in the *Engliſh* Gardens, altho' it is equally as hardy as any of the other Sorts: This is increaſed as the other Sorts, but requires a looſer Soil than they do: This is ſometimes uſed in Phyſick, and is ſuppoſed to be an Antidote to the Poiſon of the Wolf's-bane.

ACONITUM HYEMALE, *or* Winter Wolf's-bane.

The *Characters* are;

The Leaves are like thoſe of the Wolf's-bane; the Flowers (which are produced in the Center of the Leaves) are like thoſe of the Ranunculus; with many Stamina or Threads in the Center, and in all other reſpects agree with the Hellebore; to which the learned Dr. Boerhaave *hath made it a Congener.*

This is one of the earlieſt Flowers in the Spring, often appearing by the Middle of *January*, for which Reaſon it deſerves a Place in every curious Garden; it is very apt to increaſe by the Root, but ſhould not be too often tranſplanted: The beſt Time to remove the Roots is in *May* or *June*, juſt as the green Leaves are decayed, before they are quite gone off, it being very difficult afterwards to find the Roots: This Plant will thrive in almoſt any Soil or Situation.

ACRIVIOLA, [of *Acer*, ſharp, and *Viola*, Violet, *i. e.* ſharp Violet] commonly called *Naſturtium Indicum*, or *Indian Creſs.*

The *Characters* are;

The Leaves are round, umbilicated, and placed alternately; the Stalks are trailing; the Cup of the Flower is quinquifid; the Flowers conſiſt of five Leaves, which are in Form of a Violet; the Seeds are roundiſh, and rough, three of them ſucceeding each Flower.

There are five Varieties of this Plant in the *Engliſh* Gardens; *viz.*

1. ACRIVIOLA. *Frid. Cæſ. T.* 935. The leſſer *Indian* Creſs.
2. ACRIVIOLA, *flore ſulphureo. Boerh.* The leſſer yellow *Indian* Creſs.
3. ACRIVIOLA *maxima odorata. Boerh.* The great *Indian* Creſs.
4. ACRIVIOLA *maxima odorata, flore ſulphureo. Boerh.* The great yellow *Indian* Creſs.
5. ACRIVIOLA *maxima odorata, flore pleno.* The great double Naſturtium, or *Indian* Creſs.

The four firſt Sorts are commonly ſow'd in *March* or *April*, in a good Soil and warm Situation: they are great Climbers, and ſhould have a Hedge or Palliſado to run upon, to prevent their lying upon the Ground, which is apt to rot them: they begin to flower in *June* or *July*, and continue till the Froſt comes, which ſoon deſtroys the whole Plant, unleſs ſhelter'd therefrom. The Flowers are very good in Sallets, and are much in Uſe to garniſh Diſhes: The unripe Seeds afford a warm agreeable Pickle.

The double Sort producing no Seeds, is only increaſed by planting Cuttings in any of the Summer Months, and muſt be carefully preſerved in Winter, it being very ſubject to rot, if kept too cloſe, or if it hath too much Water in Winter, but muſt be intirely kept from Froſts.

This Plant, if confined in Pots fill'd with poor Soil, will be leſs ſubject to ramble, and much more productive of Flowers; whereas if it is planted in the full Ground, or potted in a rich Mould, it will extend its Branches to a great Diſtance, and the Flowers will be very thinly placed upon the Plant, ſo that the greateſt Beauty of the Plant, which conſiſts in the Number of its Flowers, is loſt. The Flowers of this Kind are much better to garniſh Diſhes than thoſe of the ſingle; but for Uſe, the ſingle is preferable to this in Sallads, being of a warmer Taſte; as is obſerved of all ſingle Flowers, that they are preferable to the double of the ſame Kinds for medicinal or other Uſes, as being much ſtronger in Smell and Taſte; for the Multiplicity of Petals deprive the Flowers of the Organs for Generation, in which are contained the Eſſence of the Flower.

ADHATODA, The Malabar Nut.

The *Characters* are;

The Leaves grow oppoſite; the Cup of the Flower is oblong, and conſiſts of one Leaf; the Flower is monopetalous, of an anomalous Figure, and conſiſts of two Lips; the uppermoſt is crooked, and is raiſed in Form of an Arch; the under Lip is divided into three Segments, and hangs downward; the Ovarium becomes the Fruit, which is in Form of a Club, and is divided into two Cells, in which are contained flat Heart-ſhaped Seeds.

There are but two *Species* of this Plant known at preſent, which are,

1. ADHATODA *Zeylaneuſium. H. L.* The common Malabar Nut.
2. ADHATODA *Indica, folio ſaligno, flore albo. Boerh.* The Willow-leav'd Malabar Nut, *commonly called*, The Snaptree.

Theſe Plants are both raiſed by Cuttings, planted in any of the Summer Months, which muſt be ſhaded and frequently water'd; about *Auguſt* they will have taken Root, and muſt then be tranſplanted into Pots, fill'd with light ſandy Earth, mix'd with rotten Dung: they muſt have a good Green-houſe in Winter, and require often but gentle Waterings: In the Summer they may be expoſed to the open Air, but ſhould be ſhelter'd by Hedges or Trees from ſtrong Winds. Theſe Trees do frequently flower in *England*, but have never, that I have heard of, produced any Fruit with us.

ADIANTHUM; *i. e.* Maiden-hair.

The *Species* are;

1. ADIANTHUM *foliis coriandri. C. B. P.* 355. Common *or* true Maiden-hair.
2. ADIANTHUM *Americanum Cornut.* 7. *American* Maiden-hair of Cornutus.
3. ADIANTHUM *nigrum officinarum. J. B.* Black Maiden-hair of the Shops.
4. ADIANTHUM *Scoticum majus, Coriandri folio. Tourn.* Greater *Scotch* Maidenhair, with a Coriander Leaf.
5. ADIANTHUM *Scoticum minus, folio obtuſo, altius inciſo. Tourn.* Leſſer *Scotch* Maiden-hair, with an obtuſe Leaf, deeply cut in.

The firſt Sort is a Native in the South Parts of *France*, and in the *Mediterranean*, where it grows on Rocks, and old Ruins, from whence it is brought into *England*, for medicinal Uſe; tho' the ſmaller Leaves of Fern are ſometimes impoſed on ignorant Perſons, by thoſe who ſupply the Markets with Herbs; but as the true Sort is not to be obtained freſh in *England*, ſo the ſurer Way is to get it from ſome knowing Druggiſt, who imports it from abroad.

The ſecond Sort is a Native of *America*, from whence it was originally brought into *Europe*, and is preſerved by curious Perſons in their Gardens. This has been formerly preſerved in the Stoves in *England*, as a very tender Plant, but it is found to be very hardy; and in *France* it is now become ſo common, as to be uſed inſtead of the common Sort, in the Shops at *Paris.*

The third Sort is common in ſeveral Parts of *England*; it grows on Buildings, Walls, and on the ſide of ſhady Banks.

The fourth and fifth Sorts have been found growing on the Rocks, in the North of *Scotland*, but as they are not commonly found, ſo they have not been introduced into the *London* Shops.

There are many other Sorts of this Plant in the *Eaſt* and *Weſt-Indies*, from whence we have received dried Samples of near thirty Sorts; but as they are Plants which are not cultivated in the *European* Gardens, ſo I ſhall not enumerate them here.

ADIANTHUM ALBUM; *vide* Ruta Muraria.

ADIANTHUM NIGRUM; *vide* Filicula.

ADNATA, ADNASCENTIA, are thoſe Off-ſets, which by a new Germination under the Earth proceed from the Lily, Narciſſus, Hyacinth, *&c.* which afterwards grow to true Roots, which the *French* call *Cayeux.*

ADONIDIS HORTI; *i. e.* the Gardens of *Adonis*, are Plants, Flowers, *&c.* in Pots or Caſes, ſet on the Outſides of Windows, in Balconies, *&c.*

ADONIS, or FLOS ADONIS, Bird's eye, or Pheaſant's-eye.

The *Characters* are;

The Leaves are like Fennel, or Chamomil; the Flowers conſiſt of many Leaves, which are expanded in Form of a Roſe; the Seeds are collected into oblong Heads.

There are but three Varieties of this Plant to be met with in the *Engliſh* Gardens; *viz.*

1. ADONIS *hortenſis, flore minore atrorubente. C. B.* The common red Bird's-eye.
2. ADONIS *ſylveſtris, flore luteo, foliis longioribus. C. B.* The long-leav'd yellow Bird's-eye.
3. ADONIS *hellebori radice, buphthalmi flore. H. L.* The Hellebore-rooted Pheaſant's-eye, *commonly called*, The Fennel-leav'd black Hellebore.

The firſt of theſe Sorts is very common in *England*, and is ſown in open Borders as an annual flowering Plant to adorn Gardens: The beſt Time to ſow it is in *Auguſt*, ſoon after the Seeds are ripe, when it rarely fails to grow, and is very hardy, ſeldom being hurt by Cold.

Theſe Plants will flower in *June* and *July*, and the Seeds will ripen ſoon after; but thoſe which are ſown in the Spring, very often fail to grow, or at leaſt remain till *June* or *July* before they appear, ſo that they ſeldom produce good Seeds the ſame Year, and rarely live over the Winter after flowering.

This Plant grows wild in ſome Parts of *England*, particularly near the River *Medway*, about three Miles above *Rocheſter* Bridge.

The yellow Sort is uncommon in *England*, and only to be found in ſome curious Gardens: This makes a pretty Diverſity with the former, and muſt have the ſame Culture.

The third Sort is ſtill more rare than any of them; it is an abiding Root, and is increaſed by parting the Roots in *Auguſt*, or by ſowing the Seeds, ſoon after they are ripe, in light ſandy Earth: The Seedlings will be two Years before they blow, but the Off-ſets will flower the ſucceeding Spring: This produces its Flowers in *March*, or early in *April*, and is not a deſpicable Plant in the moſt curious Gardens.

This Plant is uſed in Medicine by the *Germans*, as the true Hellebore.

ÆTHER, ['Αἰθὴρ, of αἴθειν, *Gr.* to burn or flame; ſome of the Antients having ſuppoſed it to be of the Nature of Fire:] It is uſually underſtood to be a thin ſubtile Matter or *Medium*, much finer and rarer than Air itſelf, which commences from the Limits of the Atmoſphere, and poſſeſſes the whole heavenly Space. See *Atmoſphere* and *Air*.

AGERATUM, ['Αγήρατον, of α Priv. and γῆρας, Old Age, becauſe it does not wither, nor eaſily grow old.] Maudlin.

The *Characters* are;

The Flowers are digeſted into looſe Umbels; but in other reſpects, it is very like the Coaſtmary.

There are ſeveral *Species* of this Plant preſerved in the Botanick Gardens; but as there are not above three Sorts which (either for Uſe or Beauty) deſerve to be cultivated, I ſhall only mention thoſe, and paſs over the reſt.

1. AGERATUM *foliis ſerratis. C. B.* The common Maudlin.

2. AGERATUM, *quæ ptarmica incana, pinnulis criſtatis. T. Voy.* The hoary Oriental Maudlin.

3. AGERATUM *Peruvianum, arboreum, folio lato, ſerrato. Boerh.* The Peruvian Tree Maudlin, *falſely called*, The Jeſuit's Bark Tree.

The firſt of theſe Plants is propagated in Gardens, for medicinal Uſe; it is increaſed by parting the Roots either in Spring or Autumn, and requires a light Soil and open Situation, where it will thrive abundantly.

The ſecond Sort is ſomewhat tender, and muſt have a dry Soil and warm Situation: This is increaſed by planting the Cuttings in any of the Summer Months. This Plant was ſuppoſed by the Antients to be what produced the Worm-ſeed; but this is confuted by all the Moderns: however, it deſerves a Place in a Garden, for its fine hoary Leaves, together with its Umbels of yellow Flowers, which continue moſt Part of the Summer.

The third Sort grows to a Shrub of eight and ten Feet in Height; it is increaſed by planting the Cuttings in any of the Summer Months, or by laying down the Branches: It requires frequent Waterings, and muſt be houſed in hard Winters, but will endure our common Winters in the open Air. This Tree, when it firſt came into *England*, was ſuppoſed to be the Tree from which the *Peruvian Bark* was taken; but this has been confuted long ſince: There is no great Beauty in it, but it may have a Place in a Collection for its Oddneſs.

The Plants before mentioned are by Dr. *Tournefort* referr'd to *Ptarmica*, of which they are Species according to his Method: but as the firſt Species ſtands in the *Diſpenſatory* under the Title of *Ageratum*, ſo I thought proper to continue it under that Name, and have here ſubjoined ſome Plants which agree with *Tournefort*'s Characters of *Ageratum*.

The *Characters* are;

It hath a perſonated Flower conſiſting of one Leaf, the under Part of which is tubulous, but the upper Part is divided into two Lips, the upper one being divided into two, and the under one into three Parts: The Piſtil which ariſes from the Flower-cup, afterwards becomes an oblong membranaceous Fruit, divided into two Cells, in which are contained many ſmall Seeds.

The *Species* are;

1. AGERATUM *ſerratum, Alpinum, glabrum, flore purpuraſcente. Tourn.* Smooth Ageratum of the *Alps*, with a Purpliſh Flower.

2. AGERATUM *Americanum, erectum, ſpicatum, flore purpureo. Houſt. American* Ageratum, with purple Flowers growing in a Spike.

3. AGERATUM *Americanum, procumbens, gnaphalii facie, floribus ad foliorum nodos. Houſt.* Creeping *American* Ageratum, having the Face of Cud-weed, and the Flowers coming out at the ſetting on of the Foot-ſtalks.

4. AGERATUM *Americanum, fruteſcens, chamædryos folio, floribus ex foliorum alis. Houſt.* Shrubby *American* Ageratum, with a Germander Leaf, and the Flowers growing from the ſetting on of the Leaves.

The firſt Sort being a Native of the *Alps*, is very hardy in reſpect to Cold, but muſt have a ſtrong Soil, and not too much expoſed to the Sun: This is propagated by parting of the Roots; the beſt Time for doing of this is in *September*. This Plant grows very cloſe to the Ground, and has been uſed in ſome Parts of *England* to make Edgings for Borders; but near *London*, where the Soil is hot, and has been dunged, it is very difficult to maintain this Plant. It flowers in *June*, but rarely produces ripe Seeds in *England*.

The other three Sorts were diſcovered in *America* by the late ingenious Dr. *William Houſtoun*, who ſent the Seeds of theſe Plants into *Europe*. The Seeds of theſe three Sorts muſt be ſown on a Hot-bed in the Spring; and when the Plants are fit to tranſplant, they ſhould be placed each into a ſmall Pot filled with light Earth, and placed into a moderate Hot-bed, obſerving to water and ſhade them until they have taken Root, after which they muſt have Air and Water in proportion to the Seaſon and the Warmth of the Bed in which they are placed. In Autumn theſe Plants will flower, and if they are placed in a Stove, will perfect their Seeds in Winter. They may alſo be continued thro' the Winter in a Stove, and will flower early the following Summer, ſo that good Seeds may be obtain'd by this Method; but they rarely continue longer than two Summers, ſo that they muſt be conſtantly raiſed from Seeds every Year.

AGNUS CASTUS: *vide* Vitex.

AGRIFOLIUM: *vide* Aquifolium.

AGRIMONIA, [of 'Αργεμώνη, becauſe it is good againſt the αργέματα, *i. e.* the Fault of the Eyes] Agrimony, Aȝꞃimonia, *Anglo-Saxon*.

The *Characters* are;

The Leaves are rough, hairy, pennated, and grow alternately on the Branches; the Calyx (or Flower-cup) conſiſts of one Leaf, which is divided into five Segments: the Flowers have five or ſix Leaves, and are form'd into a long Spike, which expand in Form of a Roſe: the Fruit is oblong, dry, and prickly, like the Burdock; *in each of which are contain'd two Kernels.*

The *Species* are;

1. AGRIMONIA *officinarum. Tourn.* The common *or* medicinal Agrimony.

2. AGRIMONIA *odorata. Camer.* The ſweet ſmelling Agrimony.

3. AGRIMONIA *minor, flore albo. Hort. Cath.* Leſſer Agrimony, with a white Flower.

4. AGRIMONIA *orientalis, humilis, radice craſſiſſima, repente, fructu in ſpicam brevem & denſam congeſtis. T. Cor.* Dwarf Eaſtern Agrimony, with thick creeping Roots, and the Fruit growing in ſhort thick Spikes.

The firſt of theſe Sorts is common in the Hedges in many Parts of *England*, and is the Sort commonly uſed in Medicine, but ſhould not be wanting in a Garden: It will grow in almoſt any Soil or Situation, and is increaſed by parting the Roots in Autumn, or by ſowing the Seeds ſoon after they are ripe.

The ſweet-ſmelling Agrimony is by ſome preferr'd to the common Sort for medicinal Uſes; but however it is certainly the moſt grateful to infuſe for pectoral Decoctions, and makes a pleaſant kind of Tea: It is propagated as the common Sort, but requires an opener Expoſure.

The third and fourth Sorts are preſerved in the Gardens of ſuch Perſons who are curious in botanical Inquiries; but as they are not uſed in Medicine, ſo they are ſeldom cultivated in other Gardens. They are both very hardy Plants, and may be propagated by ſowing of their Seeds on a Bed of light Earth, in the Spring, or by parting their Roots in Autumn, and when the Plants are come up, they will require no farther Care than only to keep 'em clear from Weeds, until they are large enough to tranſplant, when they may be planted in an open Bed of light Earth, where they will thrive, and endure the ſevereſt Cold of our Climate, as well as the common Sort.

AGRIMONOIDES; Baſtard Agrimony.

The *Characters* are;

It hath a roſaceous Flower, conſiſting of ſeveral Petals, which are placed in a circular Order, iſſuing out of the Diviſions of the Flower-cup; but the Flower and the Flower-cup are received into another Funnel-ſhaped Empalement, which is fringed. The

Flower-cup afterwards becomes a ſharp oval Fruit, which is infolded in the outer Empalement, and contains, for the moſt part, a ſingle Seed.

There is but one *Species* of this Plant at preſent known, which is;

AGRIMONOIDES; *Col. part* 1. 145.

This is a perennial Plant, which in its outward Appearance greatly reſembles Agrimony, but differs therefrom in its Flower; for which Reaſon Dr. *Tournefort* has ſeparated it from the Agrimonies. It may be propagated by Seeds, which ſhould be ſown in the Autumn, ſoon after they are ripe; for if they are kept out of the Ground till Spring, they are ſubject to miſcarry, or otherwiſe will remain in the Ground till the following Spring; whereas thoſe which are ſown in Autumn, do ſeldom fail to come up the next Spring. When the Plants appear, they will require no other Culture, but to keep them clear from Weeds until the following Autumn, when they ſhould be taken up and tranſplanted where they are to remain. Theſe Plants will grow in almoſt any Soil or Situation, provided they are not placed under the Drip of Trees.

The ſecond Year theſe Plants will produce Flowers and the Roots will abide ſeveral Years, and may be parted in Autumn, if you are willing to propagate them that Way.

AHOUAI.

The *Characters* are;

It hath a Funnel-ſhaped Flower, conſiſting of one Leaf, and is divided into ſeveral Parts at the Top; from whoſe Cup ariſes the Pointal, which is fixed like a Nail to the inner Part of the Flower, which afterwards becomes a fleſhy Fruit, almoſt of a Pear-ſhape, in which is incloſed a three-corner'd Nut.

The *Species* are,

1. AHOUAI. *Thev. Franc. Antarct.* 66.
2. AHOUAI *nerii folio, flore luteo. Plum.* Ahouai, with an Oleander Leaf, and a yellow Flower.

Theſe two Plants grow in great Plenty on the Continent in the Southern Parts of *America*, but are leſs common in the Iſlands of *America*. The firſt of them grows to the Height of our common Cherry-trees; the Leaves are three or four Inches long, and almoſt two Inches broad. The whole Tree is full of a milky Juice, which flows out on breaking or wounding any Part of it; the Wood of this Tree ſtinks moſt abominably; and the Kernel of the Nut is a moſt deadly Poiſon, ſo that the *Indians* always caution their Children againſt eating of it, for they know of no Antidote to expel this Poiſon, nor will they uſe the Wood of this Tree for Fuel; but they take the Kernel out of the Shell, into which they put ſmall Stones, and then bore a Hole thro' each Shell, and ſtring them; theſe they tye about their Legs, to dance with, as is the Cuſtom of our Morris-dancers with Bells.

The ſecond Sort is of much lower Growth than the firſt, and ſeldom riſes above ten or twelve Feet high. The Fruit of this Tree is of a beautiful red Colour when ripe, but the whole Plant abounds with a milky Juice as the former, and I believe is equally poiſonous. I received the Seeds of this Plant from *Panama*, which were collected by Mr. *Robert Millar* Surgeon, in the Year 1735; they came up in a Hot-bed very well, and ſome of the Plants produced Flowers the ſame Year.

Theſe Plants may be propagated from their Nuts, which ſhould be put into ſmall Pots fill'd with light Earth, and plunged into a Hot-bed of Tanners Bark, obſerving to water them frequently to promote their Vegetation. When the Plants are come up about two Inches high, they ſhould be tranſplanted each into a ſeparate Pot, filled with freſh light Earth, and plunged again into a Hot-bed of Tanners-bark, obſerving to ſhade the Glaſſes in the Heat of the Day, until the Plants have taken new Root; and they muſt be frequently refreſhed with Water. As the Summer advances, ſo theſe Plants ſhould have Air admitted to them, in proportion to the Warmth of the Seaſon; and when they have filled theſe ſmall Pots with their Roots, they ſhould be turned out, and tranſplanted into other Pots of a larger Size, which muſt alſo be filled with freſh light Earth, and then ſhould be plunged into the Hot-bed again, obſerving to water them frequently, as alſo to admit Air under the Glaſſes every Day, in proportion to the Warmth of the Seaſon. When the Plants are grown about a Foot high, they ſhould have a larger Share of Air, in order to harden them before the Winter; but they ſhould not be wholly expoſed to the open Air the firſt Year, becauſe it will ſtunt their Growth. In the Winter theſe Plants ſhould be placed in a warm Stove, and during that Seaſon they ſhould be frequently refreſhed with Water, but it muſt not be given to them in great Quantities in cold Weather, leſt it ſhould rot their Roots. In the following Spring theſe Plants ſhould be ſhifted again into other Pots, at which Time you ſhould take away as much as you conveniently can of the old Earth from their Roots, and afterwards cut off the decayed Fibres, then put them into Pots filled with light rich Earth, and if you have Conveniency to plunge them into a moderate Hot-bed of Tanners-bark, it will greatly promote their taking new Root. In *June* following theſe Plants ſhould be inured to bear the open Air by Degrees, into which they ſhould be removed toward the latter End of the ſame Month; but they ſhould be placed in a warm Situation, where they may be ſheltered from ſtrong Winds: In ſuch a Situation they will bear the open Air of our Climate very well until *September*, when they ſhould be again removed into the Stove, and muſt be managed during the Winter Seaſon, as was before directed. Theſe Plants produce their Flowers plentifully in *Auguſt*, but they have not as yet produced any Fruit in this Country. They retain their Leaves all the Year, which being thick, ſtrong, and of a ſhining green Colour, make a pretty Variety amongſt other tender Exotick Plants in the Winter Seaſon, for which they are chiefly eſteemed.

AIR, [Aer, *Lat.* Ἀῆρ, of τοῦ ἀεὶ εἶν, becauſe it always flows; or as others, of ἄημι, to breathe; or as others, of τοῦ αἴρειν, becauſe it bears the Earth.] By *Air* is meant all that fluid expanded Maſs of Matter which ſurrounds our Earth, in which we live and walk, and which we are continually receiving and caſting out again by Reſpiration.

The Subſtance whereof *Air* conſiſts, may be reduced to two Kinds; *viz.*

1. The Matter of Light or Fire, which is continually flowing into it from the heavenly Bodies.
2. Thoſe numberleſs Particles, which in Form either of Vapours or dry Exhalations, are raiſed from the *Earth*, *Water*, *Minerals*, *Vegetables*, *Animals*, &c. either by the *ſolar*, *ſubterraneous*, or *culinary* Fire.

Elementary Air, or *Air* properly ſo call'd, is a certain ſubtile, homogeneous, elaſtick Matter, the Baſis or fundamental Ingredient of the Atmoſpherical *Air*, and that which gives it the Denomination.

Air therefore may be conſider'd in two Reſpects, either as it is an univerſal Aſſemblage or *Chaos* of all kinds of Bodies; or as it is a Body endued with its own proper Qualities.

1. That there is Fire contain'd in all *Air* is demonſtrable, in that it is evident, that there is Fire exiſting in all Bodies; and to this Fire it is that *Air* ſeems to owe all its Fluidity; and were the *Air* totally diveſted of that Fire, it is more than probable that it would coaleſce into a ſolid Body; for it is found by many Experiments, that the *Air* condenſes, and contracts itſelf ſo much the more, the leſs Degree of Warmth it has; and, on the contrary, expands itſelf the more, according as the Heat is greater.

2. In reſpect of *Exhalations*, *Air* may be ſaid to be a general Collection of all kinds of Bodies; for there are no Bodies but what Fire will render volatile and diſperſe into *Air*; even Salts, Sulphurs, and Stones, nay and Gold itſelf, tho' the heavieſt and moſt fixed of all Bodies, are convertible into Vapours by a large Burning glaſs, and are carried on high.

Thoſe floating Particles thus raiſed from terreſtrial Bodies, are moved and agitated by the fiery Particles divers Ways, and are diffuſed thro' the whole Atmoſphere.

Of the Matters thus raiſed in the Atmoſphere, thoſe which come from fluid Bodies, are properly called *Vapours*, and thoſe from ſolid or dry ones, *Exhalations*.

The Cauſe of this Volatility and Aſcent is the Fire, without which all Things would fall immediately down towards the Center of the Earth, and remain in eternal Reſt.

Thus if the *Air* be full of Vapours, and the Cold ſucceeds, thoſe Vapours before diſperſed are congregated and condenſed into Clouds, and thus fall back again into the Form of *Water*, *Rain*, *Snow*, or *Hail*.

From the Time of the Entrance of the Spring till Autumn, the Evaporation is conſtant; but then it begins to fail, and in the Winter ceaſes, to lay up freſh Matter for the coming Seaſon.

And thus it is that froſty Winters, by congealing the Waters, and by covering the Earth with a Cruſt, and thus impriſoning the Exhalations, make a fruitful Summer.

And this ſeems to be the Reaſon why in ſome Countries, where the Winter is ſeverer than ordinary, the Spring is more than ordinary fruitful: For in ſuch Places the Exhalations being pent up a long time, are diſcharged in the greater Quantity, when the Sun makes them a Paſſage; whereas under a feebler Cold, the Flux would have been continual, and conſequently no great Stock reſerved for the next Occaſion.

This vaporous Matter then being at length received into the Atmoſphere, is return'd again in the Form of Rain, a Forerunner of a cheerful Crop.

As the Sun retires, the Cold ſucceeds; and thus the Diverſity of the Seaſons of the Year depends on a Change in the Face of the Cruſt of the Earth, the Preſence of the Air, and the Courſe of the Sun.

And hence we conceive the Nature of Meteors, which are all either Collections of ſuch Vapours, and Exhalations, or Diſperſions thereof.

Collections of Vapours make Clouds, which being farther and farther condenſed, turn to Snow, Rain, or Hail.

The ſubtiler Oils are always riſing into the Air: Now two Clouds, partly form'd of ſuch Oils, happening to meet and mix, by the Attrition the Oil frequently takes Fire, and hence proceed Thunder, Lightenings, and other Phænomena; which may be farther promoted by the Diſpoſition of the Clouds to favour the Excitation.

And hence ariſe great and ſudden Alterations in the Air; inſomuch that it ſhall now be intenſely hot, and raiſe the Spirits perhaps to 88 Degrees in a Thermometer; and yet, after a Clap of Thunder with a Shower, it ſhall fall again in a few Minutes no leſs than 20 or 30 Degrees.

Ice may be, and is form'd even in the Heavens, from the intenſe Cold that frequently prevails there; and the Sun's Rays paſſing duly thro' the Ice, have their Force conſiderably increaſed; as we ſee in Burning-glaſſes made of Ice.

And hence our Degree of Heat may be greatly heightened; as accordingly we obſerve, that when our Atmoſphere is replete with Clouds, provided they are not groſs enough to intercept the Rays, our Heat is then moſt intenſe and ſultry.

It is known that none of theſe Clouds are above an *Engliſh* Mile high; and even the white ones, in fair Weather, are rarely found to be more than three quarters of a Mile, and ſeldom above half a Mile from the Surface of the Earth, and on very high Mountains the Warmth is inconſiderable.

In effect, our Heat depends more on the Circumſtances of the Clouds, and the Bodies that are beneath them, than on all that is above them, taking Sun, Moon, Stars and all.

It is therefore impoſſible to pronounce what the Degree of Heat will be in any given Place at any Time, even tho' we know ever ſo well the Places and Poſition of the Sun and Planets with reſpect to us, ſince it depends ſo much upon other variable Things, no ways capable of being aſcertained.

The Height or Depth of the *Air* makes a yet farther conſiderable Alteration therein; for the Exhalations are few of them able to aſcend above the Tops of Mountains; and on ſome Mountains in *Bavaria* it is Winter, and on the other Side Summer at the ſame Time; ſo that while this Side is parched with Heat, that lies buried in Snow: And the Inhabitants on one Side of a Mountain have all periſhed with the Plague, while thoſe of the other Side have remained in perfect Health.

The lower the Place, the cloſer, denſer, and heavier is the *Air*, till at length you arrive at a Depth where the Fire goes out: ſo that Miners, who go deep, to remedy this Inconvenience, are forced to have Recourſe to an artificial Wind, raiſed by the Fall of Waters, to do the Office of the other *Air*.

The *Air* may likewiſe undergo ſome Alterations by Means of its Motion: Thus a briſk Wind leſſens the Preſſure of the incumbent Atmoſphere; by which means the ſubterraneous Air may be enabled to raiſe the Cruſt of the Earth, or occaſion a ſhuddering of it: And hence proceeds Mr. *Hawkſby*'s Obſervation, that the Barometer ſinks very notably when the Wind is raiſed, or the *Air* agitated about the ſame Time.

Now conſidering the *Air* as ſuch a *Chaos* or Aſſemblage of all Kinds of Bodies, and a *Chaos* ſo extremely liable to change, it muſt needs have a great Influence on vegetable Bodies.

In general, the *Air*, as it contains divers Kinds of Exhalations, has a wonderful Effect towards promoting, ſtopping or altering the Actions of all Bodies on each other: ſo if pure well-fermented Wine be carried into a Place where the Air is repleniſhed with the Fumes of new Wine next fermenting, it will begin to ferment afreſh: And from the *Air*, conſider'd as before, do ariſe many aſtoniſhing Effects.

The *Air* is every where in continual Motion; for in the ſtilleſt Seaſon, when no Wind is ſtirring, if a Perſon places himſelf in a darken'd Room, which only receives the Light in at a little Hole, capable of admitting a ſingle Ray; that Ray dividing itſelf, and illuminating the whole Length of the Room, he may perceive every Thing, all the external Objects, whoſe Species are brought in Motion, which is owing to the external Air, which inſinuating itſelf thro' the Chinks of the Edifice, moves that on the Outſide of the Chamber. And hence, The Mercury in a very large accurate *Barometer* is found to be continually vibrating or leaping up and down, without ever remaining a Moment quiet.

This perpetual Motion of the *Air* is owing to Fire, which acts there on the true, proper *Air*, by means of its native Elaſticity.

Others ſay, the Cauſe from whence the *Air*, which is compoſed of ſo many heterogeneous Particles, receives its ſudden and continual Motion, is properly the *Æther*, or the ſubtile and celeſtial Matter, and from it the *Corpuſcula* in the Air acquire their Force and Motion; and beſides, one Part moves another by the ſame Means; and by how much ſmaller the Bodies are, by ſo much is their Motion the more ſudden; and this is done inceſſantly, tho' we cannot perceive it.

Theſe Particles of *Air* are very light, yet nevertheleſs they have their Weight, according to their Proportion and Degree of Levity.

The Motion of the *Air*, and conſequently its Force and Effect, ariſe wholly from Fire, by moving all the various Kinds of Particles which are in the Air, and performs infinite Operations.

In the extremeſt Cold, the *Air* ſcarce acts at all, but is contracted within itſelf; but when warm, expands again, and agitates other Bodies; conſequently as the Degrees of Heat are infinite, ſo muſt the Actions and Effects of the *Air* be: Add, that as the Fire acts on all the Corpuſcles that are in the Air, and theſe are infinite, it is evident that all the Actions thereof are indefinite.

3. *Air* conſider'd in itſelf, or that properly call'd *Air*.

Beſides the Fire and Exhalations contain'd in the circumambient Atmoſphere, there is a third Matter, which is what we properly mean by *Air*.

To define the Nature of it would be extremely difficult, inaſmuch as its intimate Affections are unknown to us: All we know is,

1. That *Air* is naturally an homogeneous ſimilar Body.
2. That it is fluid.
3. That it is heavy.
4. That it is elaſtick.
5. That it rarefies by Fire, and contracts by Cold.
6. That it is compreſſible by a Weight laid thereon, and riſes, and reſtores itſelf upon a Removal of the ſame: All which Circumſtances ſhould incline it to coaleſce into a Solid, if Fire were wanting.

1. *Air* is divided into *real* and *permanent*, and *apparent* or *tranſient*.

Real Air is not reducible by any Compreſſion or Condenſation, or the like, into any Subſtance beſides *Air*.

Tranſient Air is the contrary of the former, and by Cold, &c. may be condenſed into original Water: The Difference between *permanent* and *tranſient Air* amounts to the ſame as that between Vapour and Exhalation; the one, *e. g.* being dry, and the other moiſt.

Hence, as Sir *Iſaac Newton* ſays, it is, that as the Particles of *permanent Air* are groſſer, and ariſe from denſer Bodies than thoſe of tranſient Air or Vapour, *true Air* is more pondrous than Vapour, and a moiſt Atmoſphere lighter than a dry one.

But this *real Air* no where conſiſts in its Purity; but that *Air* which concerns us, and the Properties and Effects of which are chiefly to be conſider'd, is that which has been before treated on and deſcribed, which Mr. *Boyle* acknowledges to be the moſt heterogeneous Body in the Univerſe; and Dr. *Boerhaave* ſhews to be an univerſal *Chaos* and Colluvies of all the Kinds of created Bodies in the Univerſe, and in which may be found whatever Fire can volatilize.

2. That the *Air* is *fluid*, appears from the eaſy Paſſage it affords to Bodies thro' it; as in the Propagation of Sounds, Smells, and other Effluvia: For theſe Things ſhew it a Body that gives way to any Force impreſſed; and in yielding are eaſily moved among themſelves, which are the Properties of a Fluid: ſo that ſcarce any Body will call in queſtion, whether *Air* be a *Fluid*, and thence being always in Motion, and always moving other Bodies; for no Surface of any Liquor that is contiguous to the *Air*, can be at reſt.

3. As to the *Gravity* or *Heavineſs* of the *Air*, that is likewiſe eaſily proved; for that the *Air* is heavy, follows from its being a Body, Weight being an eſſential Property of Matter.

Senſe and Experiment ſufficiently prove this; for, if a Perſon lay his Hand upon an open Veſſel placed on an Air Pump, and the *Air* be exhauſted, he will ſenſibly feel the Load of the incumbent Atmoſphere to increaſe, and preſs upon the upper Part of his Hand, as the *Air* is exhauſting.

In like manner, a hollow Sphere of five or ſix Inches diameter, divided into two Segments exactly fitting each other, after the *Air* is exhauſted out of them, are preſſed together with a Force equal to an hundred Pounds Weight, and require the Strength of two ſtrong Perſons to pull them aſunder; which, as ſoon as ever the *Air* is let into them again, will fall aſunder by the mere Weight of the under Hemiſphere.

The Elements of all Bodies are as heavy as the Elements of Gold, and Variety of Bodies, in point of Weight, ariſes only from the particular Surface which thoſe Particles acquire in the Contexture: Thus, if Gold be beaten into very thin Leaves, it will ſwim in Water, or be carried about by the Air; ſo that it does not appear, that the leaſt Particles of *Air* are more porous than thoſe of Gold.

Again, that the *Air* has Gravity, is demonſtrable, in that it may actually be weighed; and a Bladder blown full of Air, weighs more than when it was empty.

Mr. *Boyle* found that a Lamb's Bladder containing about Two-thirds of a Pint, and blown up, and well dried, loſt about a Grain and One-eighth, when it was prick'd, and the Air let out.

Mr. *Graveſende* found, that the Air in a Glaſs Ball of about 283 Inches Capacity, weigh'd an hundred Grains; and according to *Burcher de Volder*, a Cubit Foot of *Air* is in Weight one Ounce and twenty-ſeven Grains.

Mr. *Boyle* has computed, that the Weight of any Quantity of *Air*, near the Surface of the Earth, is to Water as 1 to 1000; and Dr. *Halley*, as 1 to 800; and Mr. *Hawkſby*, as 1 to 885, and the Gravity of the ſame Quantity of *Air* to the ſame Quantity of *Mercury*, as 1 to 10800.

As to the Uſe and Effects of this Preſſure of the *Air*, the Weight of the whole incumbent *Air* is ſuch as enables it to ſuſtain the Mercury in the *Torricellian* Tube to the Height of 28 Inches, and Water to that of 32 Feet: But the Weight or Gravity of the *Air* is continually varying, according to the different Degree of Heat and Cold; and Experiments made in different Places neceſſarily vary in regard of the different Heights of the Places, and the Differences of *Air* ariſing therefrom: And ſo the Mercury in a Barometer is found to deſcend a fourth-part of an Inch for every 100 Foot of Aſcent.

Air therefore may be conſider'd as an univerſal *Operculum* or Cover, which by its Weight keeps all terreſtrial Bodies down, and hinders them from flying off.

4. The *Air* is *elaſtick*. Elaſticity is a Quality whereby a Body yields to any external Impreſſion, by contracting itſelf into leſs Compaſs; and upon removing or diminiſhing the impreſſive Power, returns to its former Space or Figure: And by this Quality, the *Air* is diſtinguiſh'd from all other Bodies in the Atmoſphere; neither Fire nor Exhalations appearing to be elaſtick, at leaſt in any notable Degree.

That there is ſuch a Quality in the *Air*, is evident from innumerable Experiments; and this Property is inſeparable from it: A Bladder full blown being ſqueez'd in the Hand, the included Air may be ſenſibly perceived to reſiſt the Touch; ſo that upon ceaſing to compreſs it, the Cavities or Impreſſions which were made in its Surface are immediately expanded again and filled up.

Alſo thin Glaſs Bubbles, or Bladders full of *Air*, and exactly cloſed and put into the Receiver of an *Air Pump*, the *Air* being exhauſted out of the Receiver, the Glaſs Bubbles fly in Pieces by the Force of the *Air* included in them.

Again, if a Bladder quite flaccid, having but a very little Quantity of Air included in it, be put into a Receiver, and the Air exhauſted out of the Receiver, the Bladder will ſwell as the Air is exhauſted, till it be quite full.

This *Niſus*, or Endeavour to expand itſelf, is always exerted by every Particle of *Air*; and thus ſtrives againſt an equal Endeavour of the ambient Particles of *Air*: But as the Reſiſtance happens by any means to be weaken'd, it immediately diffuſes itſelf into a vaſt Extent.

This Power or Property of the *Air* does not ſeem to have any Limits aſſigned it. Mr. *Boyle*, by ſeveral Experiments, dilated it firſt into 9 times its Space, then into 31, then into 60, then into 150; afterwards it was brought to dilate into 8000 times its Space, then into 10000, and at laſt into 13679 times its Space; and all by its own expanſive Force, without any Help of Fire.

From theſe Experiments, and many others, it appears, that the *Air* we breathe near the Surface of the Earth is compreſs'd by its own Weight into at leaſt 13679 Parts of the Space it would poſſeſs *in Vacuo*: And if the ſame *Air* be condenſed by Art, the Space it will occupy, when moſt dilated, will be as 505000 to 1, to that which it poſſeſſes when condenſed: And Dr. *Wallis* ſuggeſts, that we are far from knowing the utmoſt it is capable of.

Nor does this Power appear capable by any Means to be deſtroy'd or diminiſh'd: For Mr. *Boyle* made ſeveral Experiments to diſcover how long *Air*, brought to the greateſt Degree of Expanſion he could reduce it to in his *Air Pump*, would retain its Spring, and could never obſerve any ſenſible Diminution; altho' the *Air* was clogg'd ſome Months with a Weight that one would admire how it ſhould ſupport one Moment.

It is, indeed, a wonderful Property in *Air*, that it ſhould be capable of being contracted and extended infinitely; but, as hath been ſaid, it does not appear, by all the Experiments yet tried, that there are any Limits of its Compreſſion or Expanſion; but ſtill by the Addition of a new Weight it will contract farther, and by taking the Weight away, will expand farther.

This wonderful Property has given Occaſion to ſeveral learned Perſons to examine into the Structure of the *Air*, or Figure of its Particles, and to form ſome Conception or Idea as to the Structure of it.

Mr. *Boyle* conceives the *Air* to be a Congeries of minute *Floſculi*, all ſpringy, expanſible, and contractible, and ſuppoſes it to derive its elaſtick Force from its Structure, or the Form of theſe *Floſculi*, which he reſembles to Fleeces of Wool: Which if ſeveral Fleeces be laid one upon another, and they be compreſs'd by the Hand, or any Weight, have an elaſtick Force, and upon the Removal of the Preſſure, will riſe again.

Others reſemble the Particles of the *Air* to the Springs of Watches coil'd up, and endeavouring to reſtore themſelves.

Others to very ſlender Wires of different Subſtances, Conſiſtences, Lengths, and Thickneſſes; in greater Curls, or leſs; nearer to, or remoter from each other, &c. yet all continuing ſpringy, expanſible, and compreſſible.

Others compare them to thin Shavings of different Kinds of Wood, various in their Length, Breadth, and Thickneſs.

Sir *Iſaac Newton* conſiders *Air*, as to the Effects alone, without concerning himſelf as to the Figure of its Particles, and obſerves, that theſe aerial Particles exert certain new Powers in approaching nearer each other, whereby they mutually endeavour to recede or fly from each other: ſo that the farther they are apart, this Force does act the leſs; and the ſtronger, the nearer: And thus he brings the Inſtance of *Air* and *Vapours*, which ſeem to diſcover ſome ſuch repelling Power, as an Argument of the ſame Power's being found in other Bodies.

Tho' either of theſe Hypotheſes may be ſufficient, yet the former aſſumes or takes the more for granted, ſince it ſuppoſes the *Air* to be fleecy; whereas, according to the latter, the Particles of the *Air* may be of any Figure at Pleaſure, provided they are but allow'd the *Vis recedendi*; but ſome who have moſt accurately and ingeniouſly conſider'd it, have confeſſed, that they do not know what the *Air* is.

5. *Air* rarefies by Fire, and contracts by Cold.

The colder the *Air* is, the leſs Space it takes up; and, on the contrary, the warmer the *Air* is it poſſeſſes, the larger the Space; and ſo Cooling and Compreſſion have the ſame Effects upon *Air*; and ſo Cold and Compreſſion keep Pace with one another.

The ſame holds of warming and diminiſhing of Weight, or Heat and Expanſion, which go Hand in Hand.

And to the ſame elaſtick Power before-mention'd, and its being expanded by Heat, it is owing, that *Air* incloſed in Glaſs Veſſels, at a time when it is much condenſed, when it afterwards comes to expand by a farther Degree of Heat, frequently burſts the Bottles.

All thoſe Perſons who have travelled the higheſt Mountains, agree, that the *Air* is colder in high Places than near the Surface of the Earth; and, of Conſequence, the *Air* there muſt contract itſelf more in Proportion; yet notwithſtanding the *Air* of the ſame Places conſider'd, as it is preſs'd with a leſs Load of incumbent *Air*, muſt expand itſelf more. And hence it is, that Barometrical Experiments, made on the Tops of the higheſt Mountains, are frequently very wavering and precarious.

6. *Air* is compreſſible by a Weight laid thereon, and riſes and reſtores itſelf upon a Removal of the ſame. This Property has been ſufficiently ſhewn by what has been ſaid before, and eſpecially under the Head of Elaſticity: Wherefore, having conſidered the Properties of *Air*, I ſhall take notice of ſome of its Operations and Effects as to the Buſineſs of Vegetation.

Air, by being heavy and fluid, inveſts the whole Earth, and preſſes all the Bodies thereon with a great Force, equal to what they would ſuſtain from the Preſſure of a Column of 29 Inches depth of Mercury, or 32 Feet of Water, and conſtringes and binds them down with a Force amounting, according to the Computation of Mr. *Paſchal*, to 2232 Pounds Weight upon every ſquare Foot, or upwards of 15 Pounds upon every ſquare Inch. Hence it prevents, *e. g.* the arterial Veſſels of Plants and Animals from being too much diſtended by the *Impetus* of the circulating Juices, or by the elaſtick Force of the *Air* ſo plentifully lodged in the Blood of one, and the Sap of the other. For,

The *Air* preſſes equally every Way, as is confirmed in what we obſerve of ſoft Bodies ſuſtaining this Preſſure without any Change of Figure, and brittle Bodies without their breaking.

Air is a principal Cauſe of the Vegetation of *Plants*, an Inſtance of which we have from Mr. *Ray*, in the *Philoſophical Tranſactions*, of Lettice-ſeed, that was ſown in the Glaſs Receiver of the *Air Pump*, which was exhauſted and clear'd from all *Air*, which grew not at all in eight Days time; whereas ſome of the ſame Seed that was ſown at the ſame time in the open *Air*, was riſen to the Height of an Inch and an half in that time; but the *Air* being let into the empty Receiver, the Seed grew up to the Height of two or three Inches in the ſpace of one Week.

Another Inſtance of the Uſefulneſs of the *Air* in Vegetation, is the *Sedum*, which will puſh out Roots without Earth and Water, and live for ſeveral Months: And ſome Sorts of Aloes, if hung up in a Room intirely ſecured from Froſts, will remain freſh for ſome Years, tho' they will ſenſibly loſe in their Weight.

Air is capable of penetrating the porous and ſpongy Parts of Plants, and being there contracted, and dilating itſelf again.

The *Air* operates alſo within the Bowels of the Earth, and by its Subtilty perſpiring thro' the Pores, aſſiſts in the Rarefaction of the Crudities of the Earth, and in the diſpelling all ſuperfluous Moiſture, entering into the very Pores and Veins of the Trees, Plants, Herbs, &c. carrying along with it thoſe Salts contain'd either in itſelf, or lodged in the Earth; which Salts or Juices are alter'd according to the ſeveral Figures or Dimenſions of the different Strainers or Veſſels of thoſe ſeveral Plants which grow upon the ſame Spot of Earth, which is ſo impregnated with theſe Salts: And thence thoſe Varieties in Taſte and Smell proceed, notwithſtanding they all receive their Nouriſhment from the ſame Stock that is lodg'd in the Earth.

The *Air* alſo affects the Branches, Leaves, and Flowers of Trees, Plants, and Herbs, entering and perſpiring thro' them, and even thro' the Bark and Body of the Tree; and by the ſame kind of Subtility it does, by its refreſhing Breezes, moderate the Intenſeneſs of the Sun-beams, cooling, chearing, blowing, opening, and extending all the Offspring of Nature.

The *Air* fixes and inſinuates its aerial Subſtance into the liquid Sap of Vegetables, and as all the Agitations in Nature proceed from the Contrariety of Parts inhabiting together, ſo in this aerial and liquid Subſtances being mix'd, cauſe this Agitation and Motion in Vegetables, or, more properly, ſet it all into a Ferment, (whether it be in the Roots or in the Stem) and riſes by Co-operation of the Sun (which is the third Agent in Vegetation) up to the Top of a Tree, &c. as Liquids riſe by Fire to the Top of the containing Veſſel.

This *Air*, we find, produces a vibratory Motion in ſeveral Bodies, and particularly in Plants; the Air Veſſels thereof do the Office of Lungs: For the *Air* contain'd in them, ſometimes contracting and ſometimes expanding, according as the Heat is increaſed or diminiſhed, preſſes the Veſſels, and eaſes them again by Turns, and thus promotes a Circulation of their Juices, which could ſcarce be otherwiſe effected.

Air ſays the learned Dr. *Hales*, is a fine elaſtick Fluid, with Particles of very different Natures floating in it, whereby it is admirably fitted by the great Author of Nature to be the Breath or Life of Vegetables as well as Animals, without which they can no more live nor thrive than Animals can.

As a Proof of the great Quantities of *Air* in Vegetables, he refers to the third Chapter of his excellent Treatiſe of *Vegetable Staticks*, where, he ſays, in the Experiments on *Vines*, the great Quantity of *Air* was viſible, which was continually aſcending thro' the *Sap* in the Tubes; which manifeſtly ſhews what Plenty of it is taken in by Vegetables, and is perſpired off with the Sap thro' the Leaves.

He adds ſeveral Experiments, as to an *Apple-Branch*, *Apricot-Branch*, *Birch*, and other Plants, to prove the ſame Thing.

And Dr. *Grew* has obſerved, that the Pores are ſo large in the Trunks of ſome Plants, as in the better ſort of thick walking Canes, that they are viſible to a good Eye without a Glaſs; but with a Glaſs, the Cane ſeems as if ſtuck at Top full of Holes with great Pins, ſo large as very well to reſemble the Pores of the Skin in the Ends of the Fingers, and Ball of the Hand.

In the Leaves of Pines, they are likewiſe thro' a Glaſs a very elegant Shew, ſtanding almoſt exactly in Rank and File thro' the Length of the Leaves.

Whence it may be thought probable, that the *Air* freely enters Plants, not only with the principal Fund of Nouriſhment by the Roots, but alſo thro' the Surface of their Trunks and Leaves, eſpecially at Night, when they are changed from a perſpiring, to a ſtrongly imbibing State.

Mr. *Hales* likewiſe tells us, that in all thoſe Experiments that he tried to this Purpoſe, he found that the *Air* enter'd very ſlowly at the Bark of young Shoots and Branches, but much more freely thro' old Bark; and that in different Kinds of Trees it had different Degrees of more or leſs free Entrance.

And likewiſe, that there is ſome *Air* both in an elaſtick and unelaſtick State, mix'd with the Earth, (which may well enter the Roots with the Nouriſhment) he found by ſeveral Experiments, which he gives in the before-mentioned Treatiſe.

The excellent Mr. *Boyle*, in making many Experiments on the *Air*, among other Diſcoveries found, that a good Quantity of *Air* was producible from Vegetables, by putting Grapes, Plums, Gooſberies, Peas, and ſeveral other Sorts of Fruits and Grains into exhauſted and unexhauſted Receivers, where they continued for ſeveral Days emitting great Quantities of *Air*.

This put the curious Dr. *Hales* upon farther Reſearches to find out what Proportion of *Air* he could obtain out of the different Vegetables in which it was lodged and incorporated, which he performed by divers *chimio-ſtatical* Experiments, which he gives in many Inſtances in his Treatiſe of Analyſis of the *Air*, plainly ſhewing in what Manner he performed them, and the Events of them.

That from half a Cubick Inch, or 135 Grains of *Heart of Oak*, freſh cut from a growing Tree, there were 108 Cubick Inches of *Air* generated, which is a Quantity equal to 216 times the Bulk of the Piece of Oak; that the Weight of it was above 30 Grains, one quarter Part of the Weight of 135 Grains.

And he adds, that he took the like Quantity of thin Shavings from the ſame Piece of Oak, and dried them at ſome Diſtance from a gentle Fire for 24 Hours; in which Time they evaporated 44 Grains of Moiſture; which 44 Grains deducted from 135 Grains, there remain 91 Grains for the ſolid Part of the Oak: Then 30 Grains will be One-third of the Weight of the ſolid Part of the Oak.

He gives another Experiment of *Indian* Wheat, which grew in his own Garden, that he took 388 Grains of it, when it was not come to its full Maturity, and that there were generated from it 270 Cubick Inches of *Air*; the Weight of which *Air* was 77 Grains, *viz.* One-fourth of the Weight of the Wheat.

And again, that a Cubick Inch, or 318 Grains of Peas generated 396 Cubick Inches of *Air*, or 113 Grains, *i. e.* ſomething more than One-third of the Weight of the Peas.

And again, that from one Ounce, or 437 Grains of Muſtard-ſeed, 270 Cubick Inches of *Air* were generated, or 77 Grains, which is more than One-ſixth Part of the Ounce Weight.

He likewiſe adds, that there is a great Plenty of *Air* incorporated into the Subſtance of *Vegetables*, which, by the Action of Fermentation, is rouz'd into an elaſtick State, as is evident from theſe Experiments following.

On the ſecond Day of *March*, he poured 42 Cubick Inches of Ale from the Ton, which had been there ſet to ferment 34 Hours before into a Bolt-head; and from that Time, to the 9th of *June*, it generated 639 Cubick Inches of *Air*, with a very unequal Progreſſion, more or leſs as the Weather was warm, cool, or cold, and ſometimes upon a Change from warm to cool, it reſorbed *Air*, in all 32 Cubick Inches.

From the 2d of *March* to the 16th of *April*, 12 Cubick Inches of *Malaga* Raiſins, with 18 Cubick Inches of Water, generated 411 Cubick Inches of *Air*; and then again, it reſorb'd 35 Cubick Inches in two or three cold Days: From the 21ſt of *April* to the 16th of *May*, it generated 78 Cubick Inches; after which, the 9th of *June*, it continued in a reſorbing State, ſo as to reſorb 13 Cubick Inches: That there were at that Seaſon many hot Days, with much Thunder and Lightning, which deſtroys the Elaſticity of the *Air*: ſo there were generated in all 489 Cubick Inches, of which 48 were abſorb'd. The Liquor was at laſt vapid.

On the 10th of *Auguſt*, 26 Cubick Inches of Apples being marſhed, they generated 986 Cubick Inches of *Air* in 13 Days time, which is a Quantity equal to 48 times their Bulk; after which they did reſorb a Quantity equal to their Bulk, in three or four Days, notwithſtanding the Weather was then very hot; after which Time they were ſtationary for many Days, neither generating nor abſorbing.

From which before-mention'd Experiments on *Raiſins* and *Ale*, the ingenious Author concludes, that Wine and Ale do not turn vapid in warm Weather by imbibing the *Air*, but by fermenting and generating too much; by which Means they are deprived of their enlivening Principle the *Air*: For which Reaſon theſe Liquors are beſt preſerved in cool Cellars, whereby this active invigorating Principle is kept within due Bounds, which when they exceed, Wines are upon the Fret, and are in Danger of being ſpoil'd.

Upon theſe and many other Experiments, which the learned Author has given in his aforeſaid Treatiſe, he obſerves, that this *Air* which ariſes in ſo great Quantities from fermenting and diſſolving Vegetables, is *true permanent Air*, which is certain, by its continuing in the ſame expanded and elaſtick State for many Weeks and Months, which expanded watery Vapours will not do, but ſoon condenſe when cold.

Upon the whole, he concludes, that *Air* abounds in Vegetable Subſtances, and bears a conſiderable Part in them: And if all the Parts of Matter were only endowed with a ſtrongly attracting Power, whole Nature would then immediately become one unactive cohering Lump.

Wherefore it was abſolutely neceſſary, in order to the actuating this vaſt Maſs of attracting Matter, that there ſhould be every where mix'd with it a due Proportion of ſtrongly repelling elaſtick Particles, which might enliven the whole Maſs, by the inceſſant Action between them and the attracting Particles.

And ſince theſe elaſtick Particles are continually in great abundance reduced by the Power of the ſtrong Attracters, from an elaſtick to a fix'd State; it was therefore neceſſary that theſe Particles ſhould be endued with a Property of reſuming their elaſtick State, whenever they were diſengaged from that Maſs in which they were fix'd, that thereby this beautiful Frame of Things might be maintain'd in a continual Round of the Production and Diſſolution of Vegetables as well as animal Bodies.

The *Air* is very inſtrumental in the Production and Growth of Vegetables, both by invigorating their ſeveral Juices, while in an elaſtick active State, and alſo by greatly contributing in a fix'd State, to the Union and firm Connexion of the ſeveral conſtituent Parts of thoſe Bodies, *viz.* their *Water*, *Fire*, *Salt*, and *Earth*.

To conclude, by reaſon of thoſe Properties of the *Air* beforementioned, it is very ſerviceable to Vegetables, in that it blows up and breaks open the Clouds, thoſe Treaſures of Rain, which fertilizes the Vegetable Kind.

The *Air* alſo helps to waft away or diſperſe thoſe foggy humid Vapours which ariſe from the Earth, and would otherwiſe ſtagnate, and poiſon the whole Face of the Earth.

The *Air*, by the Aſſiſtance of the *Sun*, aſſumes and ſublimates thoſe Vapours into the upper Regions; and theſe foggy humid Vapours are, by this Sublimation, and the coercive Power of the *Air* and *Sun*, rarefied and made of ſecond Uſe in Vegetation.

And, on the contrary, to the benign Quality of the *Air*, which is ſo many Ways ſubſervient to Vegetables; ſo it is alſo ſometimes, and upon ſome Accounts, injurious and pernicious to them; not only to the ligneous, herbaceous and flowery Parts above, but alſo to the Roots and Fibres below: for in that the *Air* penetrates into the Earth, it is eaſy to be concluded, that a dry, huſky, ſcorching *Air* may be very prejudicial to the tender Fibres of new-planted Trees.

It may be likewiſe ſuppoſed, that all Bodies of Earth are more or leſs capable of imbibing the *fluid Air*, and of attracting ſuch Salts as either the *Air* can give, or the *Earth* is capable of receiving.

ALA, is the Hollow of a Stalk, which either the Leaf, or the Pedicle of the Leaf, makes with the Stalk or Branches; or it is that hollow Turning or Sinus placed between the Stalk or Branch and Leaf, from whence a new Off-ſpring is wont to put forth, which the *French* call, *Aiſſelles des Plantes.* Sometimes it is taken for a little Branch; as when they ſay, a Stock or Stem, arm'd with many *Alæ*, becauſe Branches grow to the Stock as ſo many Wings.

ALÆ is alſo uſed to ſignify thoſe *Petalæ* of papilionaceous Flowers placed between the *Vexillum* and the *Carina*, which the *French* call, *Les Ailes des Fleurs legumineuſes.*

ALÆ is alſo uſed for thoſe extreme ſlender membranaceous Parts of certain Seeds; as in the *Bignonia*, *Plumeria*, the Fruit of the Maple, *&c.* which the *French* call *Semences aîlées.* Again,

ALÆ is uſed for thoſe foliaceous Membranes which run the whole Length of the Stem; whence it is called, *Caulis alatus*, a winged Stem; in *French*, *Tige aîlée.*

ALABASTRA, are thoſe green herbaceous Leaves that encompaſs Flowers. *Jungius* explains *Alabaſtrum* to be the Globe, or roundiſh Bud, that is but juſt peeping out.

ALATERNOIDES, [*Alaternus* and εἶδος, *Gr.* Form or Shape] a Sort of Alaternus.

The *Characters* are;

This differs from the Alaternus, *in having three Seeds joined together, in the manner of the* Tithymalus, *(or Spurge) whereas the* Alaternus *has three Seeds incloſed with one common Covering, and appears to be a ſingle Berry, till it is opened.*

There are, at preſent, but three *Species* of this Plant known in the *Engliſh* Gardens; *viz.*

1. ALATERNOIDES *Africana, lauri ſerratæ folio. Com. Præl.* The African *Alaternoides*, with ſerrated Bay-leaves.
2. ALATERNOIDES *Africana, Ericæ foliis, floribus albicantibus & muſcoſis. H. Amſt.* The African *Alaternoides*, with Leaves like the Heath, and white Flowers.
3. ALATERNOIDES *Africana, Telephii, legitimi Imperati folio, flore viridi. H. Amſt.* The African *Alaternoides*, with Leaves like the true Orpine of *Imperatus*, and green Flowers.

The firſt of theſe Sorts has been an old Inhabitant of the *Engliſh* Gardens, and is ſtill continued by Perſons that are curious in Collections of Plants; but it hath no very great Beauty, being with great Difficulty reducible to any tolerable Shape, and the Flowers (which but ſeldom appear with us) afford no great Proſpect, being very ſmall, and of a greeniſh yellow Colour.

This is eaſily increaſed by planting Cuttings, in any of the Summer Months, in a ſhady Border, which do readily take Root, but muſt be potted and houſed in Winter with Myrtles, *&c.*

The ſecond Sort has been lately introduced amongſt us, and is, at preſent, rare in *England*; this is a very beautiful Plant, producing large Tufts of fine white Flowers, in *November*, *December*, and *January*, which is a Seaſon that few Plants are in Flower in the Green-houſe.

This is thought pretty difficult to increaſe; but I planted only ſix Cuttings of it in a Pot of light freſh Earth, and plunged the Pot into a cool Bed of Tanners Bark, in *September*; and five of the ſix Cuttings grew, and made fine Plants.

And I believe that to be the beſt Seaſon to plant the Cuttings, it being the Time when the Plant begins to ſhoot, and prepare for flowering.

This muſt be houſed, and kept in the ſame Green-houſe with Oranges, *&c.*

The third Sort is yet more rare than the ſecond, and is in very few Gardens at preſent: This is increaſed by planting Cuttings in *June* or *July*, keeping them ſhaded and water'd till they have taken Root: at *Michaelmas* they muſt be potted, and houſed with the ſecond Sort, but this is not near ſo fine a Plant as that is.

ALATERNUS, [call'd 'Ελαιόπρινος, as tho' of ἐλαία, an Olive, and πρίνω, an Ilex] or ever-green Privet.

This Tree, Mr. *Bradley* ſays, is diſtinguiſh'd from the *Phillyrea*, only by the Leaves of this being placed alternately upon the Branches; whereas thoſe of the *Phillyrea* are produced by Pairs oppoſite to each other: But this is not the real Difference, as he might have known, had he but examined the Fruit of the two Trees, or look'd into any of the modern Botanick Writers, who have diſtinguiſh'd the *Alaternus* from the *Phillyrea*, becauſe it hath three Seeds incloſed in each Berry, whereas the *Phillyrea* has but one.

We have ſix or ſeven Varieties of this Tree in the *Engliſh* Gardens; *viz.*

1. ALATERNUS, 1. *Cluſ. Hiſp. This is commonly called,* The Broad-leav'd, *or* Common Phillyrea.
2. ALATERNUS, 1. *Cluſi foliis ex luteo variegatis.* The blotch'd Phillyrea. *Vulgo.*
3. ALATERNUS, *ſeu Phylica, foliis anguſtioribus & profundius ſerratis. H. L.* The Narrow-leav'd *Alaternus*, with ſaw'd Edges.
4. ALATERNUS, *ſeu Phylica aurea, ſive foliis ex luteo variegatis.* The Dutch Gold-edg'd *Alaternus. Vulgo.*
5. ALATERNUS, *ſeu Phylica argentea, ſive foliis ex albo variegatis.* The Siver Phillyrea. *Vulgo.*
6. ALATERNUS, *minori folio. Tourn.* The Small leav'd *Alaternus.*

The two firſt Sorts are very common in moſt old Gardens, and were formerly in much Requeſt to make ever-green Hedges, but are of late almoſt wholly diſuſed for that Purpoſe: The Branches are very apt to ſhoot ſtrong, and require often clipping in Summer, to keep them handſome; and their being ſubject to be diſplaced by ſtrong Winds, or great Snows, together with their being liable to ſuffer in hard Winters, have juſtly excluded them from fine Gardens.

However, theſe, with the third and ſixth Sorts, are very proper for Wilderneſſes of Ever-greens, or to plant in Clumps, where, by the Diverſity of their Leaves, and different Shades of Green, they very much add to the Beauty of ſuch Plantations.

The three firſt Sorts will grow to the Height of ſixteen or eighteen Feet, and, if ſuffer'd to grow without clipping, are very hardy, (eſpecially if they grow cloſe together, or amongſt other Trees) which will prevent the Froſt from piercing the Bark of the Stems, which is often the Cauſe of their Deſtruction.

The fourth and fifth Sorts are tenderer than any of the other, and require ſome Shelter in hard Weather, or are planted againſt warm Walls in Court-yards, *&c.* to cover them; where, if they are well kept, and not ſuffer'd to grow from the Walls, they afford an agreeable Proſpect.

Theſe Sorts are all increaſed, by laying down the young Branches in the Spring; which in one Year's time will have taken Root, and may be then tranſplanted out either into a Nurſery, or into the Places where they are to remain. Theſe Trees delight moſt in a light, dry, ſandy, ſtony Soil, in which, tho' they do not ſhoot ſo ſtrong as in a moiſt rich Earth, yet they are leſs ſubject to be hurt in Winter.

ALCEA, ['Αλκία, of ἀλκή, *Gr. Remedium*] Vervain Mallow.

The *Characters* are;

It hath the whole Habit of the Mallow, *or* Althæa; *but differs from both, in having its Leaves deeply divided.*

The *Species* are;

1. ALCEA *vulgaris major, flore ex rubro roſeo. C. B. P.* 316. Greater Vervain Mallow, with a Roſe-colour'd Flower.
2. ALCEA *vulgaris major, flore candidiore. C. B. P.* 316. Greater Vervain Mallow, with a white Flower.
3. ALCEA *folio rotundo laciniato. C. B. P.* 316. Vervain Mallow, with a round cut Leaf.
4. ALCEA *tenuifolia criſpa. J. B.* II. 1067. Narrow-curled-leav'd Vervain Mallow.
5. ALCEA *cannabina. C.B.P.* 316. Hemp-leav'd Vervain Mallow.
6. ALCEA *Afra, fruteſcens, groſſulariæ folio, flore parvo rubro. Boerh. Ind. Alt. African* ſhrubby Vervain Mallow, with Gooſberry Leaves and ſmall Red Flowers.
7. ALCEA *Africana, arboreſcens, malvæ folio hirſuto, flore parvo purpureo. Till. African* Tree-like Vervain Mallow, with hairy Mallow Leaves and ſmall Purple Flowers.
8. ALCEA *Afra, fruteſcens, groſſulariæ folio ampliore, unguibus florum atro-rubentibus. Act. Phil. African* ſhrubby Vervain Mallow, with larger Gooſbery Leaves, and dark red Spots at the Bottom of the Flowers.

The firſt and ſecond Sorts are common in *Germany*, *France*, and ſeveral Parts of *Europe*; but the fourth Sort is the moſt common in *England*. The firſt Sort is ordered for Medicinal Uſe; but as that is not ſo common in *England*, the third is ſubſtituted in its ſtead; and I believe either of the four firſt Sorts may be uſed indifferently. Theſe four Sorts are biennial Plants, and ſeldom continue after they have perfected Seeds: Theſe Plants may be propagated by ſowing their Seeds in the Spring, and when the Plants are come up, they ſhould be thinn'd, leaving them about a Foot aſunder, where they may remain till they flower and ſeed; for they do not bear tranſplanting well, their Roots running for the moſt part downright, to a conſiderable depth. Theſe Plants ſhould have a poor Soil; for in a rich Earth they grow too rank, and are ſubject to rot in Winter.

The fifth Sort is an abiding Plant, and is apt to creep at the Root. This may be propagated by Seeds as the former, and ſhould have a lean Soil.

The ſixth and ſeventh Sorts do riſe to the Height of eight or ten Feet, and do make handſome Shrubs: Theſe may be propagated by ſowing their Seeds in the Spring, on a Bed of light Earth, and when the Plants are come up four or five Inches high, they ſhould be each tranſplanted into a ſeparate ſmall Pot filled with freſh light Earth, obſerving to water and ſhade them until they have taken Root, after which they may be expoſed during the Summer to the open Air; but in Winter they muſt be placed in the Green-houſe with *Myrtles*, &c. obſerving to give them a large Share of Air in mild Weather, and frequently refreſh them with Water. With this Management, they will continue flowering moſt Part of the Year.

The eighth Sort is a ſeminal Variety from the ſixth Sort, from the Seeds of which I have ſeveral times had the eighth ariſe.

ALCHIMILLA, [ſo call'd, becauſe celebrated by Alchymiſts] Ladies Mantle.

The *Characters* are;

The Leaves are ſerrated; the Cup of the Flower is divided into eight Segments, which are expanded in Form of a Star; the Flowers are collected into Bunches upon the Tops of the Stalks; the Seed-veſſels contain, for the moſt part, two Seeds in each.

The *Species* are;

1. ALCHIMILLA *vulgaris. C. B.* Common Ladies Mantle.
2. ALCHIMILLA *Alpina, pubeſcens, minor. H. R. Par.* The leſſer woolly Ladies Mantle.
3. ALCHIMILLA *Alpina, quinquefolia, folio ſubtus argenteo. Tourn.* The Alpine five-leav'd Ladies Mantle, with the under Part of the Leaves white.
4. ALCHIMILLA *minor. Mor. Hort. Reg. Bleſ.* The leſſer Ladies Mantle.
5. ALCHIMILLA *Alpina pentaphyllea minima, lobis fimbriatis. Bocc. Muſ. Par.* 2. 18. Leaſt five-leav'd Ladies Mantle of the *Alps*, with fringed Leaves.
6. ALCHIMILLA *montana minima. Col. Par.* I. 146. Leaſt Mountain Ladies Mantle, *commonly called*, Parſley Breakſtone.
7. ALCHIMILLA *ſupina, gramineo folio, minore flore. Tourn.* Low Graſs-leav'd Ladies Mantle, with a ſmaller Flower.
8. ALCHIMILLA *erecta, gramineo folio, minore flore. Tourn.* Upright Graſs-leav'd Ladies Mantle with a ſmaller Flower.
9. ALCHIMILLA *gramineo folio, majori flore. Tourn.* Graſs-leav'd Ladies Mantle with a larger Flower.
10. ALCHIMILLA *linariæ folio, calyce florum albo. Tourn.* Ladies Mantle, with a Toad-flax Leaf, and a white Flower-cup.
11. ALCHIMILLA *linariæ folio, calyce florum ſubluteo. Tourn.* Ladies Mantle, with a Toadflax Leaf, and a yellowiſh Flower-cup.
12. ALCHIMILLA *orientalis, linariæ folio breviſſimo, calyce florum albo. Tourn. Cor.* Eaſtern Ladies Mantle, with a very ſhort Toadflax Leaf, and a white Flower-cup.
13. ALCHIMILLA *Græca, kali folio, calyce florum albido. Tourn. Cor. Greek* Ladies Mantle, with a Glaſſwort Leaf, and a whitiſh Flower-cup.

The firſt Sort is a Plant ſometimes uſed in Phyſick, and is gathered frequently in moiſt Meadows, and at ſome Diſtance from *London*. This may be kept in a Garden, if planted in a moiſt Soil, and is increaſed by parting the Roots.

The ſecond Sort is a much leſs Plant than the firſt, and is woolly or ſoft to the Touch; but this Plant, when cultivated in a good Soil, will grow to be almoſt as big as the firſt.

The third Sort is found wild in *Weſtmorland*, and other Northern Parts of *England*: This, with the two former, are preſerved in curious Botanick Gardens; but as there is little Beauty in them, they are ſeldom planted in Gardens for Pleaſure: They are all propagated by parting their Roots, or ſowing their Seeds ſoon after they are ripe.

Theſe Plants are many of them preſerved in Botanick Gardens for Variety; they all grow wild in *England*, *Holland*, and *Flanders*, except the two laſt mentioned, which Monſ. *Tournefort* found in his Voyage to the *Levant*. They are moſt of them annual Plants, ſo if they are permitted to ſhed their Seeds in the Autumn, the Plants will come up, and require no other Culture, but to keep them clear from Weeds. The ſixth Sort is an annual Plant which grows in great Plenty on Heaths, and other uncultivated Places in diverſe Parts of *England*, and if it is tranſplanted into a Garden, and permitted to ſhed its Seeds, will maintain itſelf without any farther Care. This Plant is often brought to the Markets in *London*, and ſold for *Rupture-wort*, which is a very different Plant from this, but doth not grow wild near *London*.

ALDER-TREE: *Vide* Alnus.

ALESANDER, *or* ALEXANDER: *Vide* Smyrnium.

ALKEKENGI, Winter Cherry.

The *Characters* are;

It hath a Flower, which conſiſts of one Leaf, and is expanded at the Top, but of a pentagonal Figure: The Fruit (which is about the Bigneſs of a Cherry) is incloſed in the Cup of the Flower, which ſwells over it in Form of a Bladder.

The *Species* are;

1. ALKEKENGI *officinarum. Tourn.* Common Winter Cherry of the Shops.
2. ALKEKENGI *officinarum, foliis variegatis. Tourn.* Common Winter Cherry, with variegated Leaves.

3. Alkekengi *fructu parvo, verticillato. Tourn.* Winter Cherry, with ſmall Fruit growing in Whorles round the Stalks.

4. Alkekengi *Virginianum, fructu luteo. Tourn. Virginian* Winter Cherry, with yellow Fruit.

5. Alkekengi *Indicum, majus. Tourn.* Greater *Indian* Winter Cherry.

6. Alkekengi *Americanum, annuum, ramoſiſſimum, fructu ex luteo-vireſcenti. Houſt. American* annual branching Winter Cherry, with a yellowiſh green Fruit.

7. Alkekengi *Americanum, annuum, maximum, viſcoſum. Houſt.* The largeſt annual *American* Winter Cherry.

8. Alkekengi *Barbadenſe, patulum, parvo flore, fructu amplo, mucrone productiori. Act. Phil.* N° 399. Dwarf *Barbadoes* Winter Cherry, with a ſmall Flower, and an ample pointed Fruit.

9. Alkekengi *Curaſſavicum, foliis organi incanis, flore viete ſulphureo, fundo purpureo. Boerh. Ind. Alt.* 11. 66. Hoary Winter Cherry from *Curaſſo*, with Origany Leaves, and Sulphur-colour'd Flowers with Purple Bottoms.

10. Alkekengi *Americanum, fruteſcens, fructu globoſo rubro, veſica atro-purpurea. Houſt.* Shrubby *American* Winter Cherry, with a round red Fruit, having a dark Purple Bladder.

The firſt Sort is very common in the *Engliſh* Gardens, where it is preſerved for the Appearance of its firſt Fruit, which is ripe in *October*, and continues often till the Middle of *December*; it is about the Size of a common Cherry, and of a fine red Colour. This Fruit is incloſed in a Bladder, which when ripe burſts, and expoſes the Fruit to Sight. It may be propagated by ſowing of the Seeds in the Spring, or by the Roots, which creep very much, ſo that if they are not confined, they will ſoon overſpread a large Tract of Ground; therefore to have them more beautiful, they ſhould be confined in Pots, which ſhould be placed in the Shade in Summer, and if conſtantly watered in dry Weather, will produce great Numbers of Fruit. This Sort is ordered for Medicinal Uſe by the College of Phyſicians. The ſecond Sort is a Variety of the firſt, differing only in having variegated Leaves. This may be managed as the former.

The third, ninth, and tenth Sorts are abiding Plants, which require to be ſheltered from the Cold in Winter. The third Sort grows to a Shrub of about three Feet high, and produces great Numbers of Fruit annually: This may be propagated by ſowing of the Seeds on a moderate Hot-bed in the Spring, and when the Plants are come up two Inches high, they ſhould be tranſplanted on another Hot-bed, obſerving to water and ſhade them until they have taken new Root, after which Time they muſt have a large Share of Air, otherwiſe they will draw up very weak. In *June* theſe Plants ſhould be potted, and placed in a ſhady Situation, until they have taken Root, after which they may be expoſed to the open Air in Summer; but in Winter they muſt be placed in a warm Green-houſe.

The ninth Sort creeps very much at the Root, ſo is eaſily propagated by parting the Roots in the Spring. This muſt be houſed in Winter as the former, but may be expoſed in Summer: It produces Flowers annually, but has not produced any Fruit in *England*.

The tenth Sort grows to the Height of ten or twelve Feet: This is propagated by ſowing of the Seeds on a Hot-bed in the Spring, and muſt be afterwards potted, as hath been directed for the third Sort; but this muſt be placed in a Stove in Winter, it being the tendereſt of all the Sorts here mentioned.

The fourth, fifth, ſixth, ſeventh, and eighth Sorts are annual Plants, and require to be raiſed on a Hot-bed in the Spring; and when the Plants are come up two Inches high, they ſhould be tranſplanted to another moderate Hot-bed, obſerving to water and ſhade them until they have taken Root, after which Time they muſt have a large Share of freſh Air; and in *June* they may be taken up with a Ball of Earth to their Roots, and tranſplanted either into Pots or Borders of light Earth, where they may remain to perfect their Fruit.

ALLELUJAH: *Vide* Oxys.

ALLIARIA, Sauce alone, *or* Jack by the Hedge: *Vide* Heſperis.

ALLIUM, [of ’Αλέω, *Gr.* to avoid or ſhun, becauſe many ſhun the Smell of it.] Garlick.

The *Characters* are;

It hath a bulbous Root conſiſting of many ſmall Tubercles included in the Coverings (or Coats) thereof; the Leaves are plain; the Flowers conſiſt of ſix Leaves, which are formed into a Corymbus upon the Top of the Stalks: the Flowers are ſucceeded by ſubrotund Fruit, which are divided into three Cells, in which are contained roundiſh Seeds.

There are ſeveral Varieties of this Plant, which differ in their Leaves, Manner of Flowering, Shape and Size of their Bulbs, &c. but there are not above two or three Sorts which are cultivated for Uſe; *viz.*

1. Allium *ſativum. C. B.* The Common *or* Manured Garlick.

2. Allium *ſativum, alterum, ſive Alliopraſum, caulis ſummo circumvoluto. C. B.* The Rocambole.

3. Allium *ſylveſtre, latifolium. C. B.* Ramſons. *Vulgo.*

4. Allium *ſylveſtre, amphicarpon, foliis porraceis, floribus & nucleis purpureis. Raii Syn.* Broad-leav'd Mountain Garlick, with purple Flowers.

5. Allium *ſylveſtre, bicorne, flore ex herbaceo albicante, cum triplici in ſingulis petalis ſtria atro-purpurea. Raii Syn. Ed.* 3. 370. Wild Garlick, with an herbaceous ſtriped Flower.

6. Allium *Holmenſe, ſphærico capite. Raii Syn. Ed.* 3. 370. Great round-headed Garlick of the *Holms-Iſland*.

7. Allium *bulbiferum Virginianum. Boerh. Ind. Alt. Virginian* Garlick.

The two firſt Species are eaſily propagated by planting the Cloves, or ſmall Bulbs, in *Auguſt* or *September*, in Beds about four or five Inches diſtance from each other, keeping them clean from Weeds. About the Beginning of *June* the Leaves ſhould be tied in Knots, to prevent their ſpindling, or running to Seed, which will greatly enlarge the Bulb: In the Middle of *July* the Leaves will begin to wither and decay, at which Time they ſhould be taken out of the Ground, and hang'd up in a dry Room, to prevent their rotting; and may be thus preſerved for Winter Uſe.

The third Sort was formerly in greater Eſteem than at preſent, it being rarely cultivated in Gardens, but is found wild in moiſt ſhady Places in many Parts of *England*; and may be cultivated by planting the Roots in a moiſt ſhady Border at almoſt any Time of the Year; but the beſt Seaſon is in *July*, juſt as the green Leaves are decaying.

The fourth, fifth, and ſixth Sorts, grow wild in diverſe Parts of *England*, but are by the Curious in Botany, preſerved in their Gardens for Variety. They are extreme hardy, and will thrive in almoſt any Soil or Situation, requiring no other Culture, but to keep them clear from Weeds. The beſt Seaſon to tranſplant them is in *Auguſt*, ſoon after their Leaves decay; for if they are ſuffered to remain long after, they will ſhoot out new Roots, after which time they do not bear tranſplanting ſo well.

The ſeventh Sort was brought from *Virginia* into *England*. This is alſo very hardy, and will thrive in any Soil or Situation. It produces a Cluſter of Roots on the Top of the Stalks, which, if permitted to fall on the Ground, will take Root, and thereby multiply exceedingly.

ALMOND-TREE: *Vide* Amygdalus.

ALMOND DWARF: *Vide* Perſica.

ALNUS, [ſo call'd, *quod alatur amne, Iſid. i. e.* becauſe nouriſh'd by a River.] The Alder-Tree.

The *Characters* are;

It hath Leaves reſembling thoſe of the Hazel: The Male Flowers (or Katkins) are produced at remote Diſtances from the Fruit, on the ſame Tree; the Fruit is ſquamoſe, and of a conical Figure.

There are three *Species* of this Tree in *England*; viz.

1. Alnus *rotundifolia, glutinoſa, viridis. C. B.* The Common *or* Round-leav'd Alder.

2. Alnus *folio oblongo, viridi. C. B.* The long-leav'd Alder.

3. Alnus *vulgaris, ſub-conis ligulis membranaceis rubris donata. Raii Syn. Ed.* 3. The Scarlet Alder.

This Sort was found in a Meadow near *Long-leet*, by Mr. *Brewer*, ſome Years ſince: but it is a Matter of Doubt, whether it is a diſtinct Species, or ſome accidental Variety.

Theſe Trees delight in a very moiſt Soil, where few other Trees will thrive, and are a great Improvement to ſuch Lands; They are propagated either by Layers, or planting of Truncheons about three Feet in Length, in *February*, or the Beginning of *March*, which ſhould be ſharpen'd at One End, and the Ground looſen'd with an Inſtrument before they are thruſt into it, leſt, by the Hardneſs of the Soil, the Bark ſhould be torn off, which may occaſion their Miſcarriage. They ſhould be thruſt into the Earth, at leaſt two Feet, to prevent their being blown out of the Ground by ſtrong Winds.

If you raiſe them by laying down the Branches, it muſt be perform'd in *February* or *March*; and by the *February* following, they will have taken Roots ſufficient to be tranſplanted out; which muſt be done, by digging a Hole, and looſening the Earth in the Place where each Plant is to ſtand, planting the young Tree at leaſt a Foot and a half deep, cutting off the Top to about nine Inches above the Surface, which will occaſion them to ſhoot out many Branches.

The Diſtance theſe Trees ſhould be placed, (if deſign'd for a Coppice) is ſix Feet ſquare; and if the ſmall lateral Shoots are taken off in the Spring, it will very much ſtrengthen your upright Poles, provided you leave a few ſmall Shoots at Diſtances upon the Body thereof, to detain the Sap for the Increaſe of its Bulk.

Theſe Trees may be alſo planted on the Sides of Brooks (as is uſual for Willows) where they will thrive exceedingly, and may be cut for Poles every third or fourth Year. This Wood is in great Requeſt with the Turners, and will endure a long Time under Ground, or to be laid in Water.

ALNUS, NIGRA BACCIFERA: *Vide* Frangula.

ALOE, [*Gr.* Ἀλοή.]

The *Characters* are;

The Leaves are thick and ſucculent, and for the moſt part, beſet with Spines on the Edges: The Flower conſiſts of one Leaf, is tubulous, and cut into ſix Segments at the Top, like the Hyacinth: *The Fruit is oblong and cylindrical, which is divided into three Cells, in which are contained flat, and, for the moſt part, ſemicircular Seeds.*

There is a great Variety of this Plant in the curious Gardens of Botany in *England*, which are Natives both of the *Eaſt* and *Weſt-Indies*; but moſt of the curious Sorts were brought from the Cape of *Good Hope*. I ſhall firſt enumerate their Kinds, and then proceed to their Culture.

1. ALOE *Americana muricata. J. B.* The common large *American* Aloe.

2. ALOE *Americana minor. Munt.* The leſſer *American* Aloe.

3. ALOE *Americana ex Vera Cruce, foliis anguſtioribus, minus glaucis. H. Beaum.* The Narrow-leav'd Aloe from *Vera Cruce.*

4. ALOE *Americana ex Vera Cruce, foliis latioribus & glaucis. H. H.* The broad-leav'd Aloe from *Vera Cruce.*

5. ALOE *Americana, folio viridi rigidiſſimo, fœtido, Piet dicta indigenis. H. Beaum.* The broad Green-leav'd Aloe from *Curaſſo*, with black Spines.

6. ALOE *Americana, folio viridi ſerrata,* Silk-Graſs *dicta.* The *American* Aloe, with green ſerrated Leaves, *called in the Weſt-Indies*, Silk-Graſs.

7. ALOE *Americana ſobolifera. H. L.* The *American* Aloe, which produces young Plants out of the Flower-ſtems.

8. ALOE *vulgaris. C. B.* The common *Barbadoes* Aloe.

9. ALOE *Africana, foliis glaucis, margine & dorſi parte ſuperiore ſpinoſis, flore rubro. Com. Præl.* The *African* ſtalky Aloe, with glaucous ſerrated Leaves and red Flowers.

10. ALOE *Africana cauleſcens, foliis ſpinoſis, maculis ab utraque parte albicantibus notatis. H. A.* The common large ſpotted *African* Aloe, *falſely called*, The *Carolina* Aloe.

11. ALOE *Africana cauleſcens, foliis ſpinoſis, maculis ab utraque parte albicantibus obſcurioribus, magis glaucis quam præcedens. Boerh.* The large ſpotted *African* Aloe, with Leaves more glaucous, *i. e.* bluer or grayer than the former.

12. ALOE *Africana arboreſcens, montana, non ſpinoſa, folio longiſſimo, plicatili, flore rubro. H. A.* The *African* Aloe-Tree, with flat long ſmooth Leaves without Spines.

13. ALOE *Africana cauleſcens, foliis glaucis caulem amplectentibus, dorſo integro ſpinoſo. Com. Rar.* The *African* ſtalk'd Aloe, with glaucous Leaves ſurrounding the Stalks, and Spines growing on the Back of the Leaves.

14. ALOE *Africana cauleſcens foliis glaucis, brevioribus, caulem amplectentibus foliorum parte interna & externa nonnihil ſpinoſa. Com. Rar.* The *African* Aloe, with ſhorter glaucous Leaves, ſurrounding the Stalks and Spines within and outſide of the Leaves.

15. ALOE *Africana cauleſcens, foliis glaucis breviſſimis, foliorum ſummitate interna & externa nonnihil ſpinoſa. Com. Rar.* The *African* Aloe, with the ſhorteſt glaucous Leaves, and Spines on both Sides of the Leaves at the Extremity.

16. ALOE *Africana humilis, ſpinis inermibus & verrucis obſita. Com. Rar.* The Dwarf *African* Aloe, with Leaves arm'd with Spines and Warts, *commonly called*, the Hedge-hog Aloe.

17. ALOE *Africana humilis, foliis ex albo & viridi variegatis. Com. Rar.* The Dwarf *African* Aloe, with green and white variegated Leaves, *commonly called*, the Partridge-Breaſt Aloe.

18. ALOE *Africana erecta, triangularis & triangulari folio viſcoſo. Com. Rar.* The upright triangular-leav'd viſcous Aloe.

19. ALOE *Africana erecta rotunda folio parvo, & in acumen rigidiſſimum exeunte. Com. Rar.* The upright *African* Aloe, with ſmall ſharp pointed Leaves.

20. ALOE *Africana flore rubro, folio triangulari verrucis & ab utraque parte albicantibus notato. H. A.* The triangular-leav'd *African* Aloe, with white Tubercles on every Part of the Leaf, and red Flowers.

21. ALOE *Africana margaritefera minor. H. A.* The ſmall Pearl Aloe.

22. ALOE *Africana folio in ſummitate triangulari margaratifera, flore ſubviridi. H. A.* The greater Pearl Aloe. *Vulgo.*

23. ALOE *Africana foliis planis conjugatis carinatis verrucoſis, caule & flore corallii colore. Boerh. Ind.* The *African* Aloe, with plain fleſhy Leaves growing oppoſite, and are full of Tubercles, with red Flowers.

24. ALOE *Africana minima, atro-viridis, ſpinis herbaceis numeroſis ornata. Boerh. Ind.* The leaſt *African* Aloe, with dark green Leaves, which are ſet very thick, with greeniſh Spines.

25. ALOE *Africana flore rubro, folio maculis albicantibus ab utraque parte notato. H. A.* The Tongue Aloe. *Vulgo.*

26. ALOE *Africana foliis planis latioribus minime ſerratis, carinatis, caule & flore corallii colore. Ind.* The Broad-leav'd Tongue Aloe. *Vulgo.*

27. ALOE *Africana foliis longis conjugatis, ſupra cavis margaritiferis, flore rubro elegantiſſima. Boerh. Ind.* The Pearl Tongue Aloe. *Vulgo.*

28. ALOE *Africana cauleſcens, folio craſſo obſcure viridi, ſpinis ad latera & in dorſo armato. Boerh. Ind.* The ſtalky *African* Aloe, with thick dark green Leaves arm'd with Spines on the Back-ſide of the Leaves.

29. ALOE *Africana cauleſcens, foliis glaucis caulem amplectentibus. H. A.* The ſtalky *African* Aloe, with glaucous Leaves ſurrounding the Stalks.

30. ALOE *Africana cauleſcens, foliis minus glaucis caulem amplectentibus, floribus rubris.* The Sword Aloe. *Vulgo.*

31. ALOE *Africana foliis ex albo & viridi eleganter variegatis. Hort. Beaum.* The ſtrip'd *African* Aloe.

32. ALOE *Africana, breviſſimo, craſſiſſimoque folio, flore ſubviridi. H. A.* The Cuſhion Aloe. *Vulgo.*

33. ALOE *Africana, folio triangulo longiſſimo & anguſtiſſimo, floribus luteis fœtidis. H. L.* The *African* Aloe, with long narrow triangular Leaves, and ſtinking yellow Flowers, *commonly called*, Iris Uvaria.

34. ALOE *Guineenſis, radice geniculata, foliis e viridi & atro undulatim variegatis. Com. Præl.* The *Guiney* Aloe, with knotted Roots, and undulated variegated Leaves.

35. ALOE *Zeylanica, pumila, foliis variegatis. Par. Bat.* The Dwarf *Zeylon* Aloe, with variegated Leaves.

36. ALOE *Africana cauleſcens, foliis minus glaucis caulem amplectentibus, dorſi parte ſuprema ſpinoſa. Com. Rar.* The ſtalky *African* Aloe, with leſs glaucous Leaves ſurrounding the Stalks, with Spines on the Back-ſide of the Leaves at the Extremity.

37. ALOE *Indiæ Orientalis, ſerrata, ſuccotrina vera, flore Phœnicio. H. Beaum.* The Succotrine Aloe.

38. ALOE *Africana arachnoidea. Com. Rar. Pl.* 78. *African* Cobweb Aloe. *Vulgo.*

The Soil in which theſe Plants thrive beſt, is, one half freſh light Earth from a Common, (and if the Turf is taken with it, and rotted, it is much better); the reſt ſhould be white Sea-Sand, and ſifted Lime-rubbiſh, of each an equal Part; mix theſe together ſix or eight Months at leaſt before it is uſed, obſerving to turn it over often in this Time.

The firſt of theſe *Aloes* is very hardy, in reſpect to Cold, and has, in mild Winters, endur'd abroad, being planted in a very dry Soil, and under a South Wall; but may be kept in Pots or Tubs in a common Green-houſe with Oranges, Myrtles, &c. but muſt have very little Moiſture in Winter. Moſt of the other Sorts are better preſerv'd in an airy Glaſs-Caſe, in which there is a Stove to make a little Fire in very bad Weather: to dry and warm the Air in foggy, cold, or wet Weather, and to prevent the Froſt from entering the Houſe.

The fifth, ſixth, ſeventh, eighteenth, thirty-fourth and thirty-fifth Sorts require a greater Share of Heat to preſerve them in Winter, and ſhould be ſet in a good Stove, and kept nearly to the Degree of Heat (mark'd upon Mr. *Fowler*'s Botanical Thermometers) ten Degrees above temperate. Indeed moſt of the other Sorts may be kept in the ſame Temperature of Heat in Winter, but then you muſt obſerve, that the greater the Heat is in Winter in which you keep them, the more Water they will require: And if they are well manag'd in this Heat, they will grow very much in Winter; therefore great Care muſt be taken in the ſevere Cold, that it doth not enter the Houſe, nor that the Heat be at that Time leſſen'd; as alſo how you begin to give them Air in the Spring, for the extreme Parts of the Plants will be rendered very tender, by their growing freely in Winter, and the leaſt Check to their Growth at that Seaſon, is very often their Deſtruction.

About the Beginning of *June*, moſt People (in *England*) ſet their Pots of *Aloes* out of the Houſe; but, if this be done, they ſhould be ſet under the Shelter of Hedges, or Trees, to ſcreen them from the Violence of the open Sun and Wind, which, in a few Days, will otherwiſe change their Colour, and very much diminiſh their Beauty, and very often the great Rains which fall in *June* or *July*, either rot, or fill them with ſo much Moiſture, as, in Winter, to be liable to Deſtruction with the leaſt Cold; therefore, upon the whole, it is much more adviſeable to keep them moſt Part of the Year in the Houſe, (as is the conſtant Practice in *Holland*) giving them, in good Weather, as much free open Air as is poſſible, and ſcreening them with Mats, Shutters, or Tarpawlins over the Glaſſes, from the great Heat of the Sun in the Middle of the Day.

In the Middle of *July* is a very proper Seaſon to ſhift theſe Plants; at which Time you may take them out of the Pots, and with your Fingers open the Roots, and ſhake out as much of the Earth as poſſible, taking off all dead or mouldy Roots, but do not wound or break the young freſh ones: Then fill the Pot about three Parts full of the above-mention'd Earth, putting a few Stones in the Bottom of the Pot, to drain off the Moiſture; and after placing the Roots of the Plant in ſuch a Manner as to prevent their interfering too much with each other, put in as much of the ſame Earth, as to fill the Pot almoſt to the Rim, and obſerve to ſhake the Plant, ſo as to let the Earth in between the Roots, and then with your Hand ſettle it cloſe to the Roots of the Plant, to keep it ſteady in the Pot; then water them gently, and ſet them abroad in a ſhady Place, where they may remain for three Weeks, giving them gentle Waterings, if the Weather ſhould prove hot and dry.

Toward the latter End of *Auguſt*, in a dry Day, remove them into the Houſe again, obſerving to give them as much free open Air as poſſible, while the Weather holds warm; but, if the Nights are cool, you muſt ſhut up the Glaſſes, and give them Air only in the Day; and, as the Cold increaſes, you muſt decreaſe opening the Glaſſes, but obſerve to give them gentle Waterings often, till the Middle of *October*, when you muſt abate them, according to the Heat of the Houſe in which they are kept.

The firſt Sort may be ſet abroad in the Beginning of *May*, and remain ſo till *October*; and, in dry Weather, muſt have frequent, but gentle Waterings, and ſhould be ſhifted every Year, taking off all the Suckers and rotten Roots, which, if ſuffer'd to remain on, will greatly retard the Growth of the Plant.

The thirty-third Sort is very hardy, and ſhould be planted abroad under a good South-wall, where it will thrive and increaſe much faſter than if kept in Pots, and will produce much ſtronger Flowers.

How increas'd.] Theſe *Aloes* are all increas'd by Off-ſets, which ſhould be taken from the Mother Plant, at the Time when they are ſhifted, and muſt be planted in very ſmall Pots, filled with the ſame Earth as was directed for the old Plants; but if, in taking the Suckers off, you obſerve that Part, which joined to the Mother Root, to be moiſt, you muſt let them lie out of the Ground in a ſhady dry Place two or three Days to dry before they are planted, otherwiſe they are very ſubject to rot.

After planting, let them remain in a ſhady Place (as was before directed in ſhifting the old Plants) for a Fortnight, when you ſhould remove them to a very moderate Hot-bed, plunging the Pots therein, which will greatly facilitate their taking new Roots; but obſerve to ſhade the Glaſſes in the Middle of the Day, and to give them a great deal of Air.

Toward the End of *Auguſt*, begin to harden theſe young Plants, by taking off the Glaſſes in good Weather, and by raiſing them at other times with Bricks, that the Air may freely enter the Bed, which is abſolutely neceſſary for their Growth, and to prepare them to be remov'd into the Houſe, which muſt be done toward the End of *September*, and manag'd as before directed for the old Plants.

Moſt of the *African* Sorts of *Aloes* do produce Flowers with us annually, when grown to a ſufficient Size, which is often the ſecond, and ſeldom more than the third or fourth Year, after planting from Off-ſets; but the *American Aloes* (which do, for the moſt Part, produce their Flower-ſtems immediately from the Center of the Plant) ſeldom flower till they are of a conſiderable Age, and this but once during the Life of the Plant; for when the Flower-ſtem begins to ſhoot from the Middle of the Plant, (which, for the moſt Part is of a large Size, and grows to a great Height) it draws all the Moiſture and Nouriſhment from the Leaves, ſo that, as that advances, the Leaves decay; and when the Flowers are fully blown, ſcarce any of the Leaves remain alive; but whenever this happens, the old Root ſends forth a numerous Quantity of Off-ſets for Increaſe; and it is not till this Time that ſome of theſe Sorts can be increas'd, eſpecially the ſeventh Sort, which never produces any young Plants until it flowers, at which Time the Flower-ſtem, is beſet with ſmall Heads from Bottom to Top, which being taken off, and planted, will grow as well as Suckers from the Roots.

This *Aloe*, which, with us, ſeldom makes a very large Plant, hath yet produced Flower-ſtems of a conſiderable Size, and fifteen Foot in Height. The Flowers are little leſs than thoſe of the large Sort. I can't here forbear taking Notice of a vulgar Error or two relating to the large *American Aloe*, which is, that it never flowers till it is an hundred Years old, which is a Miſtake; ſince we have had ſeveral of them flower in *England*, ſome of which were known not to exceed fifty Years old; and others, which flower'd many Years ago, cannot be ſuppoſed to have been in *England* ſo long as to arrive at that Age, ſince they were thought too tender for our Climate at that Time, when Green-houſes were not known; as may be ſeen by looking into *Gerard*'s and *Parkinſon*'s Herbals.

Another common Error is, that when the Flower opens, it makes a Report like that of firing a Gun: This is ſufficiently confuted by all thoſe who have been where theſe Plants have flower'd; but I ſuppoſe the Riſe of this Story might proceed from ſome Perſons ſaying, when one of theſe Plants flower'd, it made a great Noiſe; meaning thereby, that whenever one of them flower'd in *England*, it was ſpread abroad as an uncommon Thing, and occaſion'd a great Noiſe among the neighbouring Inhabitants, moſt of whom uſually repair to ſee it, as a Thing that rarely happens, and as a great Curioſity.

The *African Aloes* do, for the moſt part, afford Plenty of Suckers, by which they are increaſed; but thoſe few that do not, may be moſt of them propagated, by taking off ſome of the under Leaves, laying them to dry for three or four Days, as was directed for the Off-ſets; then plant them in the ſame Soil as was directed for them, putting that Part of the Leaf which did adhere to the old Plant, about an Inch, or an Inch and half (according to the Size of the Leaf) into the Earth, giving them a little Water to ſettle the Earth about them; then plunge the Pots into a moderate Hot-bed, obſerving to ſcreen them from the Violence of the Sun, and give them gentle Refreſhings with Water: The beſt Seaſon for this is in *June*, that they may puſh out Heads before Winter.

ALOIDES, [of 'Αλοὴ and εἶδος, Form] *Boerh. Ind.* Stratiotes foliis Aloes ſemine longo. *Gund. Raii Syn.* The Water *Aloe*, or Freſh-water *Soldier*.

This Plant is found in large ſtanding Waters in the Iſle of *Ely*, and in *Lincolnſhire*, but will not grow in a Garden: But if young Plants be put into an open Canal in the Spring, they will thrive and propagate therein.

ALOPECUROS, [*Gr.* 'Αλοπέκουρος] Fox-tail; a kind of Graſs.

ÆSCHYNOMENE, ['Αισχύνομος]. *Vide* Minoſa.

ALSINE, [*Gr.* 'Αλσίνη] Chick-weed.

There are ſeveral Species of this Plant, which are common in cultivated Places, and on Dunghills: Theſe being ſo well known to moſt Perſons, it will be needleſs to mention them in this Place.

ALTHÆA, ['Αλθαία of 'Αλθος, a Medicament; or 'Αλθαίνειν, *Gr.* to heal] Marſh-mallow.

The *Characters* are;

It is in all reſpects like the Mallow; *but the Leaves of theſe are generally more ſoft and woolly.*

There are ſeveral Kinds of this Plant, ſome of which riſe to the Height of eight or ten Feet, and become woody: Theſe are proper Ornaments for Quarters of Wilderneſs-work, to intermix with flowering Shrubs and Trees: They begin to flower toward the latter End of *May*, and continue till *October* (if the Weather proves good): Their long Continuance in Flower, together with their great Variety of ſoft woolly Leaves, renders them worthy of a Place in the beſt Gardens of Flowering-trees.

The different *Species* of theſe known in *England* are;

1. **ALTHÆA** *fruteſcens, folio acuto, parvo flore. C. B.* The ſhrubby Marſh-mallow, with ſharp-pointed Leaves, and ſmall Flowers.

2. **ALTHÆA** *fruteſcens, Luſitanica, folio ampliore, minus incano. Tourn.* The *Portugal* ſhrubby Marſh-mallow, with large, and leſs hoary Leaves.

3. **ALTHÆA** *fruteſcens, Luſitanica, folio ampliore, minus incano. Tourn.* The *Portugal* ſhrubby Marſh-mallow, with rounder and undulated Leaves.

4. **ALTHÆA** *fruteſcens, folio bryoniæ. C. B.* The ſhrubby Marſh-mallow, with Bryony Leaves.

5. **ALTHÆA** *flore majore. C. B.* The large flower'd Marſh-mallow.

6. **ALTHÆA** *Dioſcoridis & Plinii. C. B.* The common Marſh-mallow.

7. **ALTHÆA** *folio rotundiori, aut minus acuminato. Suther.* The rounder-leav'd Marſh-mallow.

Theſe Plants are all eaſily raiſed from Seeds which muſt be ſown in *March*, in a light dry Soil, and in two Months Time they will be fit to tranſplant in the Places where they are to remain for good, or put into Pots; that when they are remov'd, the Earth may be turn'd out of the Pots, without diſturbing the Roots, for theſe Shrubs will not bear a Remove (when grown to any conſiderable Stature); the Roots being for the moſt Part compos'd of ſtrong woody Parts, and have very few ſmall Fibres, ſo that the Earth is ſubject to fall intirely off, upon removing them; and if it ſo happen to grown Plants, they rarely are made to grow afterwards.

The ſecond Year theſe Shrubs begin to flower, and one ſingle Plant (if ſuffer'd to feed) will produce enough to raiſe many hundred Plants: They are impatient of wet in Winter, therefore ſhould be planted in a dry rubbiſhy or ſandy Soil, where they will ſtand much better than in a ſtrong rich Earth; but they are ſeldom longer-liv'd than five or ſix Years (with us), eſpecially if ſuffer'd to flower and ſeed plentifully every Year; therefore the beſt Way to preſerve them is, to cut off the extreme Parts of the Branches in *July*, that they may make freſh Shoots before Winter; this will alſo make their Heads more regular, than if they were ſuffer'd to grow rude.

They may be alſo raiſed by planting Cuttings in *May*, in a light Soil, keeping them ſhaded, and often refreſhing them with Water until they have taken root.

The five firſt-mention'd Sorts are all Strangers to our Country, and are only to be found in the Gardens of the Curious: The two laſt Sorts grow wild in many Parts of *England*, and are by ſome propagated in Gardens for phyſical Uſe: Theſe two Sorts are alſo raiſed from Seeds, or by parting the Roots early in the Spring, and will grow in almoſt any Soil or Situation. Theſe two die down to the Ground annually, and riſe again the ſucceeding Spring.

ALYSSOIDES.

The *Characters* are;

It hath a Flower in Form of a Croſs, conſiſting of four Leaves, out of whoſe Flower-cup riſes the Pointal, which afterward becomes an elliptical thick Fruit, divided into two Cells by an intermediate Partition, which is parallel to the demi-elliptical turgid Valves, and filled with round flat Seeds, having Borders round them.

The *Species* are;

1. **ALYSSOIDES** *fruticoſum, leucoii folio viridi. Tourn.* 218. Shrubby Alyſſoides, with a geen Stock-gilliflower Leaf.

2. **ALYSSOIDES** *incanum, foliis ſinuatis. Tourn.* 218. Hoary Alyſſoides, with ſinuated Leaves.

3. **ALYSSOIDES** *fruticoſum, Creticum, leucoii folio incano. Tourn. Cor.* Shrubby Alyſſoides of *Candy*, with a hoary Stockgillyflower Leaf.

4. **ALYSSOIDES** *orientalis, annua, myagri ſativi folio. Tourn. Cor.* Oriental annual Alyſſoides, with a Myagrum Leaf.

The firſt and third Sorts are perennial Plants, which riſe to the Height of two or three Feet; theſe may be propagated by ſowing their Seeds on a Border of light Earth in the Spring, and when the Plants are come up four Inches high, they may be tranſplanted into Pots filled with light freſh Earth, and placed in a ſhady Situation until they have taken new Root, when they may be expoſed to the open Air until the latter End of *October*, when they ſhould be placed under a common Hotbed Frame, where they may be ſheltered from ſevere Froſt in Winter, but they muſt have as much free Air as poſſible in mild Weather, and ſhould be frequently refreſhed with Water: The following Summer they will flower, and produce ripe Seeds, but the Plants may be continued four or five Years, by ſheltering of them in the Winter, as I have directed. They will often live thro' the Winter in the open Air, provided they are planted in a Situation where they are protected from the North and Eaſt Winds.

The ſecond Sort is a biennial Plant: This muſt be ſown on a Border of light Earth in the Spring, and when the Plants are come up three Inches high, ſome of them ſhould be potted, in order to ſhelter them in Winter; but there ſhould be ſome Plants left where they were ſown, which in a warm Seaſon will flower, and produce ripe Seeds the ſame Seaſon; but if theſe ſhould miſcarry, thoſe in the Pots may be preſerved thro' the Winter, under a common Frame; and in the ſucceeding Spring they ſhould be turned out of the Pots into the full Ground, where they will flower ſtrongly, and produce a large Quantity of Seeds.

The fourth Sort is an annual Plant: This muſt be ſown on a warm Border in the Spring, in the Place where the Plants are to remain, for it doth not bear tranſplanting well: Theſe Plants ſhould be thinned, if they come up too thick: In *Auguſt* they will flower, and in *September* they will perfect their Seeds.

ALYSSON, [᾿Αλύσσον, of ἀλύσσω, *Gr.* to be mad; ſo called, becauſe it was believ'd to have the Virtue of curing Madneſs or Rage by barely being look'd upon.] Madwort.

The *Characters* are;

The Flowers conſiſt of four Leaves, which are expanded in Form of a Croſs: The Fruit is ſhort and ſmooth, in which are contained many roundiſh Seeds.

The *Species* are;

1. **ALYSSON** *Creticum ſaxatile, foliis undulatis incanis. T. Cor.* The Alyſſon of *Candia*, with hoary undulated Leaves.

2. **ALYSSON** *halimi folio, ſemper-virens. Tourn.* The Alyſſon, with Sea Purſlane Leaves.

3. **ALYSSON** *Alpinum hirſutum luteum. Tourn.* The yellow *Alpine* Alyſſon, with hairy Leaves.

4. **ALYSSON** *perenne, montanum, incanum. Tourn.* 217. Hoary perennial Mountain Madwort.

5. **ALYSSON** *halimi folio, argenteo, anguſto. Tourn.* 217. Madwort, with a narrow Silver-colour'd Sea Purſlane Leaf.

6. **ALYSSON** *fruticoſum, incanum. Tourn.* 217. Hoary Shrub Madwort.

7. **ALYSSON** *fruticoſum, aculeatum. Tourn.* 217. Prickly Shrub Madwort.

8. **ALYSSON** *Creticum, foliis angulatis, flore violaceo. T. Cor.* *Candy* Madwort, with angular Leaves, and Violet-colour'd Flowers.

9. **ALYSSON** *Veronicæ folio. Tourn.* 217. Madwort, with a Speedwel Leaf.

10. **ALYSSON** *ſegetum, foliis auriculatis acutis. Tourn.* 217. Corn Madwort, with auriculated ſharp-pointed Leaves.

11. **ALYSSON** *ſegetum, foliis auriculatis acutis, fructu majori. Tourn.* 217. Corn Madwort, with auriculated ſharp-pointed Leaves, and a larger Fruit.

12. **ALYSSON** *incanum luteum, ſerpilli folio, majus. Tourn.* 217. Larger yellow hoary Madwort, with a Mother of Thyme Leaf.

13. **ALYSSON** *incanum, ſerpilli folio, minus. Tourn.* 217. Leſſer hoary Madwort, with a Mother of Thyme Leaf.

The firſt of theſe Sorts will grow to be near two Foot high, with a woody Stem, and may be form'd into a regular Head; and being planted in the middle of Borders, in a Flower-garden, is a very great Ornament thereto: It produces large Quantities of bright yellow Flowers in the Beginning of *April*, which continue till ſome Time in *May*, eſpecially if the Weather proves cool: When it is in Flower, the whole Plant appears, at a little Diſtance, to be nothing but Flowers, the Leaves and Stem being quite hid until you come near the Plant.

This Plant is hardy, and altho' brought from a more Southerly Climate, yet, if planted in a dry, lean, or rubbiſhy Soil, will endure our ſevereſt Winters abroad: It is increaſed by ſowing the Seeds in *March*, in a light ſandy Soil, or by planting Cuttings in *April* or *May*; which are very apt to take Root, if kept ſhaded in the Heat of the Day, and gently refreſhed with Water.

The ſecond Sort ſeldom continues above two or three Years with us, and muſt therefore be often ſown to preſerve it; or if the Seeds are ſuffered to fall, and remain upon the Ground, it will riſe again without any Trouble: This Plant ſpreads itſelf upon the Ground, and never riſes to any Height: It produces, at the Extremity of its Branches, very pretty Tufts of ſmall white Flowers; of which the Plant is ſeldom deſtitute for ſix or ſeven Months ſucceſſively; for which Reaſon it deſerves a Place in the Gardens of the Curious: This will alſo grow from Cuttings, if planted and managed as the former.

The third Sort is a very humble Plant, rarely riſing with us above two or three Inches high: It produces abundance of ſmall yellow Flowers early in the Spring, when few other Flowers appear, for which it is valuable: It is increas'd by parting the Roots in Autumn, and requires a light ſandy Earth, and to be expos'd only to the Morning Sun.

The fourth, fifth, ſixth, and ſeventh Sorts may be managed, as hath been directed for the third. Theſe will continue two or three Years, and if their Seeds are permitted to ſcatter, the Plants will come up and thrive without any further Care, than to keep them clear from Weeds.

The eighth Sort is an abiding Plant, which rarely produces Seeds in *England*, but multiplies greatly by Off-ſets, which may be planted into Pots filled with freſh light Earth, either in Spring or Autumn. Theſe Pots muſt be ſhelter'd from extreme Cold in Winter, but muſt have a great Share of Air in mild Weather. Some of the Plants may be planted on a warm Border, where they will endure the Cold of our ordinary Winters very well. This Plant produces great Quantities of Flowers early in the Spring.

The other ſix Sorts are annual Plants, which ſhould be ſown early in the Spring, on a Bed of light freſh Earth, where they are to remain, for they do not bear tranſplanting well, ſo that the Plants ſhould be thinned, and kept clear from Weeds, which is the only Culture they require. If the Seeds of theſe Sorts are ſuffered to ſcatter, the Plants will come up in Autumn, and ſtand thro' the Winter, ſo will more certainly produce good Seeds the following Summer.

AMARANTHOIDES, [of Ἀμάρανθος and εἶδος, *Gr.* Form.] Globe *Amaranthus*, or Everlaſting Flower; and by the *French*, *l'Immortal.*

The *Characters* are;

The Flowers are ſmall, and cut into four Segments, which are collected into ſquamoſe Heads; from each of theſe Scales is produced a ſingle Flower: The Ovary in the Bottom of the Flower becomes a roundiſh crooked Seed, which is contain'd in a thin Pellicule, or Skin.

There are, at preſent, four or five Varieties of this Plant in *England*, but there are but two of them valuable for a Garden of Pleaſure; the other Sorts produce ſmaller Flowers, and are much later, and require a great Heat to bring them to flower tolerably with us: The two beſt Sorts were brought from the *Eaſt-Indies* into *Europe*; but the other Sorts we have receiv'd from *Barbadoes*: I ſhall only mention the valuable Sorts, and paſs over the other, as fit only for the Curious in Botany.

1. AMARANTHOIDES, *Lychnidis folio, capitulis purpureis. Tourn.* The purple Globe Amaranthus, or Eternal Flower.
2. AMARANTHOIDES, *Lychnidis folio, capitulis argenteis.* The white (or Silver-colour'd) Globe Amaranthus, or Eternal Flower.

The firſt of theſe Plants is now become very common in every curious Garden near *London*, but the latter is, at preſent, a great Rarity: I receiv'd the Seeds of this Plant from *James Theobald*, Eſq; with ſeveral other curious Seeds which he procur'd from *China*; ſeveral of which ſucceeded very well in the Phyſick Garden at *Chelſea*.

Theſe Plants are ſome of the greateſt Beauties amongſt the whole annual Tribe: They muſt be ſown very early in a good Hot-bed, and treated as will be hereafter directed for the *Amaranths*, with this Difference only, that theſe muſt have a greater Share of Heat, and forwarded more in the Spring.

Theſe Flowers, if gathered before they decay on the Plant, and kept in a dry Place, will remain in Beauty for ſome Years, eſpecially if they are not too much expos'd to the Air: They are therefore very proper Ornaments for Ladies to wear in their Hair, and are far preferable to any artificial Flowers whatever: The Purple and White of theſe Flowers, together with ſome Varieties of the *Elichryſums* and *Xeranthemums*, will make a curious Variety of dry Flowers for Baſons to adorn Rooms in the Winter Seaſon, when few other Kinds are to be had.

The *Portugueſe* and *Spaniards* are very fond of theſe Flowers, and cultivate great Quantities of them in their Gardens, for adorning their Places of Worſhip in the Winter Time. The Seeds of this Plant being cloſely ſurrounded with a thin Skin, do appear to ſome Perſons, who are unacquainted therewith, to be only a chaffy Subſtance without any good Seeds; for the Seeds which are ſmall, and of a roundiſh Form, ſeldom quit this Covering, unleſs rubbed out; but if the Seeds are ſown with theſe Coverings over them, they will come up full as well as if taken out.

If the Autumn ſhould prove cold or wet, it will be very neceſſary to remove the Pots, with theſe Plants, into Shelter, otherwiſe they will not perfect their Seeds, eſpecially if they were not ſown very early in the Spring. If theſe Pots are preſerved in a good Green-houſe, their Flowers will make a very pretty Variety amongſt other Plants, and will continue until the Middle or latter End of *November*, provided the Weather proves not too cold: But what Flowers you intend to preſerve, ſhould be gathered ſoon after they arrive at their proper Bigneſs; for if they are ſuffer'd to remain very long after, the under Part of their Heads will change brown, and decay.

AMARANTHUS, [Ἀμάρανθος, of α Priv. and μαραίνω, *Gr.* to wither; ſo called, becauſe the Flower of this Plant being cropp'd, does not ſoon wither; but being dried, keeps the Beauty of its Colour a great while.] Amaranth.

The *Characters* are;

The Flowers have ſeemingly no Petals: the Cup of the Flower is dry and multifid; the Seeds are included in membranaceous Veſſels, which, when come to Maturity, burſt open either tranſverſly or horizontally, after the manner of Purſlane *and* Pimpernel, *in each of which are contained one or more roundiſh Seeds.*

There is a vaſt Variety of theſe Plants, both in the *Eaſt* and *Weſt Indies*; many of which are extremely beautiful, and as much deſerve our Care as any of the flowery Tribe. I ſhall here take Notice of the ſeveral Varieties which are cultivated in the *Engliſh* Gardens for their Beauty, omitting the other more common or leſs worthy Sorts, as more fit for a Botanical Diſquiſition.

1. AMARANTHUS *maximus. C. B.* The Tree Amaranth. *Vulgo.*
2. AMARANTHUS *maximus, panicula longa pendula, ſemine rubello. Raii Hiſt.* The long pendulous *Amaranth*, with reddiſh-coloured Seeds, *commonly called*, Love lies a bleeding.
3. AMARANTHUS *ſpica albeſcente habitiore. Martyn. Hiſt.* Amaranth with a thick whitiſh Spike.
4. AMARANTHUS *criſtatus, flore rubicundiſſimo. H.R.Par.* Cock's-comb Amaranth, with red Flowers.
5. AMARANTHUS *criſtatus, colore kermeſino. Boerh.* Carmine-coloured Cock's comb Amaranth.
6. AMARANTHUS *criſtatus, colore aureo. Boerh.* Gold-coloured Cock's-comb Amaranth.
7. AMARANTHUS *criſtatus, colore purpureo. Boerh.* Purple Cock's-comb Amaranth.
8. AMARANTHUS *criſtatus, colore luteo. Boerh.* Yellow Cock's-comb Amaranth.
9. AMARANTHUS *Sinenſis, foliis variis, panicula eleganter plumoſa. Martyn. Hiſt. Chineſe* Amaranth, with variegated Leaves, and a fine feather'd Panicle.
10. AMARANTHUS *tricolor. H. Eyſt.* The three-coloured Amaranth.
11. AMARANTHUS *bicolor.* The two-coloured Amaranth.

All theſe Sorts of *Amaranths* muſt be ſown on a good Hot-bed in *February*, or the Beginning of *March* at fartheſt; and in about a Fortnight's time (if the Bed is in good Temper) the Plants will riſe, when you muſt prepare another Hot-bed, covered with good rich light Earth, about four Inches thick; then raiſe up the young Plants with your Finger, ſo as not to break off the tender Roots, and prick them into your new Hot-bed about four Inches diſtance every Way, giving them a gentle Watering to ſettle the Earth to their Roots: but in doing this, be very cautious not to bear the young Plants down to the Ground by haſty Watering, which do rarely riſe again, or at leaſt ſo as to recover their former Strength, in a long Time, but very often rot in the Stems, and die quite away.

In the Heat of the Day keep them ſcreen'd with Mats from the great Heat of the Sun, and give them Air by raiſing up the Glaſſes with a ſmall Stone; and if the Glaſſes are wet, it will be proper to turn them every Day, (in good Weather) that they may dry; for the Moiſture, which is occaſioned by the Fermentation of the Dung, and Perſpiration of the Plants, is of a noxious Quality, and very unkindly to Plants, ſo that if the Weather happens to prove bad, that you can't turn your Glaſſes, it will be of great Service to your Plants, to wipe off all the Moiſture two or three times a Day with a Woollen Cloth, to prevent its dropping upon the Plants: When your Plants are firmly rooted, and begin to grow, you muſt obſerve to give them Air every Day (more or leſs, as the Weather is cold or hot) to prevent their drawing up too faſt, which greatly weakens their Stems.

In about three Weeks or a Month's time, theſe Plants will have grown ſo as to meet, and will ſtand in need of another Hot-bed, which ſhould be of a moderate Temper, and covered with the ſame rich Earth about ſix Inches thick, in which they ſhould be planted (obſerving to take them up with as much Earth about their Roots as poſſible) ſeven or eight Inches diſtance every Way, giving them ſome Water to ſettle the Earth about their Roots; but be very careful not to water them heavily, ſo as to bear down the Plants, (as was before directed) and keep them ſhaded in the Heat of the Day, until they have taken freſh Roots, and be ſure to refreſh them often (but gently) with Water, and give them Air in proportion to the Heat of the Weather, covering the Glaſſes with Mats every Night, leſt the Cold chill your Beds, and ſtop the Growth of the Plants.

In the Beginning of *May* you muſt provide another Hot-bed, which ſhould be covered with a deep Frame, that your Plants may have Room to grow: Upon this Hot-bed you muſt ſet as many three-penny Pots as can ſtand within the Compaſs of the Frame; theſe Pots muſt be filled with good rich Earth, and the Cavities between each Pot filled up with any common Earth, to prevent the Heat of the Bed from evaporating, and filling the Frame with noxious Steams; then with a Trowel, or ſome ſuch Inſtrument, take up your Plants (from the former Hot-bed) with as much Earth as poſſible to the Roots, and place each ſingle Plant in the Middle of one of the Pots, filling the Pot up with the Earth before deſcribed, and ſettle it cloſe to the Root of the Plant with your Hands; water them gently, as before, and ſhade them in the Heat of the Day from the Violence of the Sun, by covering the Glaſſes with Mats: refreſh them often with Water, and give them a good Quantity of Air in the Day-time.

In about three Weeks more, theſe Plants will have grown to a conſiderable Size and Strength, ſo that you muſt now raiſe the Glaſſes very much in the Day-time; and when the Air is ſoft, and the Sun is clouded, draw off the Glaſſes, and expoſe them to the open Air, and repeat this as often as the Weather will permit, which will harden them by degrees to be removed abroad into the Places where they are to remain the whole Seaſon: But it is not adviſeable to ſet theſe Plants out until a Week in *July*, obſerving to do it when the Air is perfectly ſoft, and, if poſſible, in a gentle Shower of Rain.

Let them at firſt be ſet near the Shelter of a Hedge for two or three Days, where they may be ſcreen'd from the Violence of the Sun, and ſtrong Winds, to which they muſt be inured by degrees: Theſe Plants, when grown to a good Stature, perſpire very freely, and muſt be every Day refreſhed with Water, if the Weather proves hot and dry, otherwiſe they will ſtunt, and never produce their Plumes ſo fine as they would do if taken Care of.

This is the proper Management, in order to have fine *Amaranths*; which, if rightly followed, and the Kinds are good, in a favourable Seaſon, will produce wonderful large fine Flowers, and are the greateſt Ornament to a good Garden for upwards of two Months: By this Method I have had Plants five or ſix Foot high, with Creſts near a Foot in Breadth; and I am perſuaded, if the Kind is good, (and there is no Want of Dung, or Conveniencies) in a kindly Seaſon, they will grow much larger.

In the Beginning of *September*, the *Amaranths* will have perfected their Seeds, ſo that you muſt make Choice of the largeſt, moſt beautiful, and leaſt branching Plants of each Kind for Seed; which you ſhould remove under Shelter, (eſpecially if the Weather proves wet, or the Nights froſty) that the Seeds may be maturely ripen'd; and in the Choice thereof, be ſure never to take any Seeds from Side-branches, nor from the Neck of the Plume, but ſuch only as are produced in the Middle thereof, which in many Plants, perhaps, may be but a ſmall Quantity; but I do aſſure you, it is thoſe only you can depend upon to have your Kinds good the ſucceeding Year.

The *Amaranthus tricolor* and *bicolor* muſt be kept longer under the Frames than the *Cock's-combs*; and in order to have them very beautiful, it will be proper to make a freſh Hot-bed in a Glaſs Caſe, or where ſuch a Conveniency is wanting, to erect ſome of the Lights which were placed over Cucumbers, round a Hot-bed, and cover thoſe with the ſame Lights on the Top, ſo as to reſemble a Glaſs Stove. On this Hot-bed you ſhould place your *Amaranths*, at ſuch a Diſtance from each other, as to allow them Room to ſpread, obſerving to refreſh them often with Water, and in warm Weather let them have plenty of freſh Air. With this Management, the Plants may be raiſed five or ſix Feet high, and their Leaves will come to the moſt beautiful Colours, after which they may be expoſed to the open Air, and removed to adorn the ſeveral Parts of the Garden.

AMBROSIA, [ſo call'd of Βρῶμα, Food, and Θεὸς, God, *q. d.* the Food of the Gods, as the Poets have feign'd.

The *Characters* are;

It hath Male floſculous Flowers, which are produced on ſeparate Parts of the ſame Plant from the Fruit, and have no viſible Petals: The Fruit which ſucceeds the Female Flowers, is ſhaped like a Club, and is prickly, containing one oblong Seed in each.

The *Species* are;

1. AMBROSIA *maritima. C. B.* The Maritime or Sea Ambroſia.
2. AMBROSIA *maritima, artemiſiæ foliis inodoris, elatior. H. L.* Taller unſavoury Sea Ambroſia.
3. AMBROSIA *Canadenſis, altiſſima, hirſuta, platani folio. Tourn.* The talleſt *Canada* Ambroſia, with rough Plane-tree Leaves.

The firſt of theſe Sorts may be ſown early in the Spring, in a Border under a warm Wall or Pale, where it will come up very well; and when the Plants are ſtrong enough to remove, they may be planted into the like warm Borders, where they will flower, and perfect their Seeds in Autumn; but if they have not a good Poſition, they ſeldom produce good Seeds in this Country.

The ſecond and third Sorts are brought from *America*, where they are very common Weeds, but with us ſhould be ſown upon a gentle Hot-bed in the Spring of the Year; and when the Plants are come up, ſhould be tranſplanted upon another moderate Bed, and expoſed to the open Air by degrees; and in *May* they ſhould be planted out into a warm Border, but, if poſſible, in a very poor Soil, which will check their luxuriant Growth, and cauſe them to flower and ſeed much ſooner than they would do if planted in a rich Soil. Theſe Plants have no great Beauty to recommend them, but for Variety they may be admitted into large Gardens.

AMENTACEOUS Flowers, [ſo called of *Amentatus*, faſtened with a String, &c. of *Amentum*, *Lat.* a String, Thong, or Latchet] are ſuch as have an Aggregate of Summits, hanging down in Form of a Rope or Cat's-Tail, which is alſo call'd an *Iulus*.

AMMI, [Ἄμμι, *Gr.*] Biſhops-weed.

The *Characters* are;

This is an umbelliferous Plant, with ſmall ſtriated Seeds: The Petals of the Flower are unequal, and ſhaped like a Heart.

The *Species* are;

1. AMMI *majus. C. B.* The greater Biſhops-weed.
2. AMMI *majus, foliis plurimum inciſis, & nonnihil criſpis. C. B.* The greater Biſhops-weed, with fine cut Leaves.
3. AMMI *perenne. M. Um.* Perennial Biſhops-weed.

The Seeds of the firſt and ſecond Kinds ſhould be ſown in an open Situation early in the Spring; and when the Plants are young, they may be prick'd out into Beds of ſandy Soil, at about ſix Inches diſtance from each other, obſerving to water them until they have taken freſh Root; after which time, they will require no more Care, but to keep them clear from Weeds, and if the Seaſon proves good, they will ripen their Seeds in Autumn. Or they may be ſown thin on a large Bed, and when the Plants are come up, where they are too thick, they may be houghed out, as is practiſed for *Carrots*, *Onions*, &c.

The Seeds of the firſt Sort are uſed in Medicine: The ſecond is a Variety of the firſt, which is accidental from the ſame Seeds: The third is an abiding Plant, which multiplies very faſt by its Root, which is very apt to ſpread far under Ground, for which Reaſon it ſhould never be planted in a good Garden. Theſe are all Varieties fitter for a Botanick, or Phyſick Garden, than for Gardens of Pleaſure.

AMOMUM PLINII: *Vide* Solanum.

AMORIS POMUM: *Vide* Lycoperſicon.

AMPHITHEATRE, [Ἀμφιθέατρον of ἀμφὶ, on both Sides, and θεάομαι, to view, *Gr.*] or Temples of View erected on a double Riſing, are great Ornaments to a large and noble Garden. If this Hill or riſing Ground is of a ſemi-circular Figure, it will ſtill be the better.

Theſe *Amphitheatres* are formed of Ever-greens, as *Hollies*, *Phillyrea's*, *Lauruſtinus's*, *Bays*, &c. obſerving to plant the ſhorteſt growing Trees in the Front, and the talleſt Trees behind, as *Pines*, *Firrs*, *Cedars* of *Lebanon*, &c.

They are alſo formed of Slopes on the Side of Hills, and covered with Turf, which, when well contrived, and kept, are a great Ornament to large Gardens.

AMYGDALUS, [Ἀμύγδαλος, *Gr.*] The Almond-Tree.

The *Characters* are;

It hath Leaves and Flowers very like thoſe of the Peach-Tree, *but the Fruit is longer, and more compreſſed; the outer green Coat is thinner and drier when ripe, and the Shell is not ſo rugged.*

The following Sorts are propagated for Sale in the Gardens near *London*.

1. Amygdalus *ſativa, fructu majore. C. B. P.* The common large *Almond*.
2. Amygdalus *dulcis, putamine molliori. C. B. P.* The Sweet *Almond*, with tender Shells.
3. Amygdalus *amara. C. B. P.* The Bitter *Almond*.
4. Amygdalus *ſativa, flore albo.* The white flowering *Almond*.

There is alſo another Tree, which is preſerved in ſome curious Gardens, that bears the Name of an *Almond*; but I have been inform'd by Perſons, who have ſeen the Flowers and Fruit of this Tree, that it is not of this Kind; yet as it hath not received any other Title that I know of, and as I never had an Opportunity to examine it myſelf, I ſhall mention it by its former Name, *viz.*

5. Amygdalus *Æthiopica, fructu holoſerico. Breyn. Cent.* The Æthiopian *Almond*, with Scarlet Fruit.

The firſt, ſecond, and third Sorts are chiefly cultivated in *England* for the Beauty of their Flowers, which are produced early in the Spring, when few other things appear, which renders them worthy of a Place in the beſt Gardens, where being intermixed with other flowering Trees, either in Wilderneſs Quarters, or in Walks, they afford a very agreeable Proſpect.

They are propagated by inoculating a Bud of theſe Trees into a Plum, Almond, or Peach-ſtock, in the Month of *July*: (The Manner of this Operation ſee under the Article of *Inoculation.*) The next Spring, when the Buds ſhoot, you may train them up either for Standards, or ſuffer them to grow for half Standards (according to your own Fancy;) and the ſecond Year, after budding, they may be removed to the Places where they are to remain. The beſt Seaſon for tranſplanting theſe Trees (if for dry Ground) is in *October*, as ſoon as the Leaves begin to decay; but for a wet Soil, *February* is much preferable, and obſerve always to bud upon Plumſtocks, for wet Ground, and Almonds or Peaches, for dry.

The *Almond* with white Flowers, is a greater Curioſity than either of the former, and being intermix'd with the other Sorts, and a few of the Cherry Plum-trees, which flower all together, add very much to the Beauty of theſe Plantations: This Sort with white Flowers, is more difficult to increaſe than either of the former, and will not take upon a Plumſtock, but muſt be either budded on a Peach or Almond.

The Sort with large Fruit, produces almoſt every Year large Quantities with us in *England*, which, if eaten before they are too dry, are little inferior to thoſe we receive from abroad; but if kept too long, they are very apt to ſhrivel up, and loſe their Plumpneſs; but in other reſpects are very good.

The *Æthiopian* Sort is tender, and requires a good Green-houſe to preſerve it in Winter; it is increaſed by planting Cuttings (that are tender, with a Joint of the laſt Year's Wood) in any of the Summer Months, in Pots of good light Earth, plunging them into a moderate Hot-bed, and keeping them ſhaded in the Heat of the Day, giving them frequent Refreſhings with Water: After they have taken Root, you muſt begin to harden them by degrees, to endure the open Air, a little before they are houſed, which will render them fitter to endure the Winter; for if they are too much drawn in Summer, they are very often deſtroyed in Winter.

Theſe Trees may be expoſed to the open Air, with Oranges, *&c.* (in a well ſhelter'd Place) during the Months of *June*, *July*, and *Auguſt*, but muſt be houſed before the hoary Froſts fall, which will very much prejudice them, if left abroad: They muſt have a very good Green-houſe in Winter, and gentle Waterings, as you obſerve the Leaves to curl; but be ſure not to over-wet them in Winter; which if once done, is ſeldom to be got dry again till Spring, and will be very prejudicial to the neighbouring Plants, by the great Damp it will occaſion in the Houſe.

ANACAMPSEROS, [Ἀνακάμψερος, of ἀνακάμπτω, to reflect or turn back, and ἔρως, Love; the *Magi* attributing to this Plant a Vertue of recalling Love:] *Telephium*, or *Rhodia Radix*; in *Engliſh*, Orpine, Live-ever, or Roſe-root.

The *Characters* are;

It hath a perennial Root: The Leaves, Stalks, Flowers, and Fruit, are like thoſe of the Houſe-leek; *but the Leaves of this Plant do not grow in a circumſcribed Order, as do thoſe of the* Houſe-leek, *but the Plant ariſes with a Stalk, upon which the Leaves are placed on every Side: the Flowers grow in Umbels, upon the Tops of the Stalks.*

The *Species* are,

1. Anacampseros *vulgo Faba craſſa. J. B.* III. 681. Common Orpine.
2. Anacampseros *purpurea. J. B.* III. 682. Purple Orpine.
3. Anacampseros *maxima. J. B.* III. 682. Greateſt Orpine.
4. Anacampseros *Luſitanica, hæmatodes, maxima. Tourn.* The greateſt red *Portugal* Orpine.
5. Anacampseros *radice roſam ſpirante, major. Tourn.* 264. Greater Roſe-root.
6. Anacampseros *radice roſam ſpirante, minor. Tourn.* 264. Leſſer Roſe-root.
7. Anacampseros *foliis eleganter variegatis.* Orpine with ſtriped Leaves.

Theſe Plants are ſeldom preſerved in Gardens of Pleaſure, therefore I ſhall paſs them over here, with only obſerving, that any of theſe Species may be cultivated by planting their Cuttings in any Part of the Summer, (except the *Rhodia Radix*, which is only propagated by parting the Roots, either in Spring or Autumn:) Theſe all love a dry Soil, and are very hardy.

The firſt Sort grows wild in many Parts of *England*; which is the Sort ſometimes uſed in Medicine, and which was ſome Years ſince in great eſteem to form green Chimney-pieces for the Summer Seaſon, which ſome People were very dexterous in making, by framing a Parcel of Laths together of the juſt Dimenſion of the Place where it was to ſtand; and then faſtening this Plant to the ſeveral Parts of it, ſo as to cover the whole with Green: And altho' this was only performed with Cuttings of the Plant, yet by giving the Whole a gentle Watering once a Week, the Plant would not only live, but ſhoot in Length, and continue freſh for two Months, and appear very handſome.

The other Sorts are preſerved by the Curious in Botany, for the ſake of Variety; theſe may be planted in Pots, filled with freſh undunged Earth, and ſhould have a ſhady Situation, where they will thrive better than if too much expoſed to the Sun. They are all very hardy (except the ſtriped Sort, which will require to be ſhelter'd in *Winter*) in reſpect to Cold, but they muſt not have too much Wet in *Winter*, which will ſometimes rot their Roots. They may be tranſplanted either in *Spring* or *Autumn*, at which times their Roots may be parted to propagate them; or they may be increaſed by planting Cuttings of either of the four firſt Sorts, in any of the *Summer* Months, which will eaſily take Root, and may afterwards be tranſplanted where they are to remain; but the two Kinds of Roſe-roots, are only propagated by parting their Roots. Theſe Plants ſhould not be placed near a Dove-houſe, for the Pigeons are ſo fond of them, that they will ſoon deſtroy them.

ANAGALLIS; Pimpernel.

The *Characters* are;

The Flower conſiſts of one Leaf, which is ſhaped like a Wheel, and cut into ſeveral Segments; the Pointal, which riſes out of the Flower-cup, is fixed like a Nail in the middle of the Flower; afterwards becomes a roundiſh Fruit, which when ripe opens tranſverſly into two Parts, one of which lies incumbent on the other, incloſing many angular Seeds which adhere to the Placenta.

The *Species* are;

1. Anagallis *phœniceo flore. C. B. P.* Male Pimpernel, with a red Flower.
2. Anagallis *cæruleo flore. C. B. P.* Female Pimpernel, with a blue Flower.
3. Anagallis *floribus obſolete purpureis. Park. Theat.* Pimpernel, with Flowers of a worn-out purple Colour.
4. Anagallis *flore albo. C. B. P.* Pimpernel, with a white Flower.
5. Anagallis *tenuifolia Monnelli. Cluſ.* Narrow-leav'd Pimpernel, with a blue Flower.

The firſt Sort is very common in the Cornfields, and other cultivated Places, in moſt Parts of *England*. The ſecond and third Sorts are ſometimes found wild in the Fields, but are leſs common than the firſt in *England*. The fourth is a Variety of the ſecond Sort, which ariſes accidentally from the Seed, ſo is not laſting. Theſe four Sorts are annual Plants, which ariſe from Seeds in the *Spring*, and are ſeldom preſerved in Gardens; but where-ever they do grow, if they are permitted to remain until they have ſcattered their Seeds, they will thrive faſt enough without any Care. The firſt and ſecond Sorts are placed amongſt the medicinal Plants in the College Diſpenſatory.

The fifth Sort is a very beautiful ſmall Plant, which ſpreads on the Ground, like the former Sorts, but produces a great Number of fine blue Flowers in *April*, *May*, and *June*, which makes a pretty Appearance: This may be propagated by ſowing of the Seeds ſoon after they are ripe, on a warm Border of light Earth, where the Plants will ariſe in the *Spring*, and ſome of them will produce Flowers the ſame Seaſon. Some of theſe Plants ſhould be planted into Pots, that they may be ſheltered in the *Winter*; for in very hard Froſts they are ſometimes deſtroyed. This Sort will abide two or three Years.

ANAGYRIS; Stinking Bean-Trefoil.

The *Characters* are;

It hath a papilionaceous (or Butterfly) Flower, whoſe Standard is ſhort when compared to the other Petals: the Pointal which riſes from the Flower-cup, afterwards becomes a Pod ſhaped like a Kidney-bean, containing many kidney-ſhaped Seeds. To which Notes ſhould be added, the Leaves grow by Trees on one common Foot-ſtalk.

The *Species* are;

1. ANAGYRIS *fœtida. C. B.* Stinking Bean-Trefoil.
2. ANAGYRIS *fœtida Cretica, oblongis foliis, luteis floribus. Barr. Icon.* Candy ſtinking Bean-Trefoil, with oblong Leaves, and yellow Flowers.

The firſt Sort grows wild in the South of *France*, as alſo in *Spain* and *Italy*: This is a Shrub which uſually ariſes to the Height of eight or ten Feet, and produces its Flowers in *April* and *May*, which are of a bright yellow Colour, growing in Spikes, ſomewhat like thoſe of the *Laburnum*, the Seeds are ſeldom perfected in this Country, which is the Reaſon of its preſent Scarcity in *England*.

The other Sort is a Native of *Candy*, and ſome of the Iſlands of the *Archipelago*; and at preſent is very rare in the *Engliſh* Gardens. This Sort hath longer Leaves than the former, and flowereth later in the *Summer*, ſo that it very rarely produces Seeds.

Theſe may be both propagated by laying down their tender Branches, in the *Spring*, obſerving in dry Weather to ſupply them with Water, which if duly performed, the Layers will have taken Root by the following *Spring*, when they ſhould be cut off from the old Plants, a little time before they begin to put out their Leaves, and planted in a warm Situation; for if they are too much expoſed to the cold Winds, they will be in danger of being deſtroyed in a hard *Winter*. This Method of propagating theſe Plants, is to ſupply their Defect in not producing ripe Seeds in this Country; for the Plants which are produced from Seeds, will be much handſomer, and will riſe to a much greater Height.

If you propagate theſe Plants from Seeds, you ſhould ſow them on a warm Border of light freſh Earth, toward the End of *March*, obſerving always to do it in dry Weather; for if much wet ſhould fall after the Seeds are in the Ground, they will rot. If the Seeds are good, and the Seaſon favourable, the Plants will appear in a Month after the Seeds were ſown; at which time you ſhould carefully clear them from Weeds, and in very dry Weather they ſhould be frequently refreſhed with Water; if theſe be duly obſerved, the Plants will be ſix or eight Inches high before *Winter*. While theſe Plants are young they will be in much greater danger of ſuffering by Froſt; therefore, if the *Winter* ſhould prove very ſevere, you ſhould ſhelter them with Mats during the Continuance of the Froſt, but in mild Weather they ſhould always be expoſed to the open Air. In *March* following you ſhould carefully take up theſe Plants, obſerving not to injure their Roots; then you muſt tranſplant them into a Nurſery-bed, placing them in Rows at a Foot diſtance, and the Plants at ſix Inches diſtance in the Rows; obſerving, if the Seaſon ſhould prove dry, to give them Water until they have taken new Root, after which time they will require no other Culture, but to keep them clear from Weeds, during the *Summer* Seaſon; but if the following *Winter* ſhould prove very ſevere, it will be proper to ſcreen them either with Mats or Peaſe-haulm, otherwiſe they may be deſtroyed. In this Bed they may remain two Years by which time they will be fit to tranſplant into the Places where they are deſigned to remain. The beſt Seaſon to remove them is in *March*, juſt before they begin to ſhoot, and obſerve not to injure their Roots, as alſo to Water them, if the Seaſon ſhould prove dry, until they have taken Root; as alſo to lay ſome Mulch on the Surface of the Ground about their Roots, to prevent the Air from penetrating to dry their Fibres, which will ſave much Trouble in watering. The fourth Year from Seeds, theſe Plants will begin to produce their Flowers, and will continue to produce Flowers every Year after, ſo will be very proper to intermix with other flowering Shrubs of the ſame Growth.

ANANAS, The Pine-Apple.

The *Characters* are;

It hath a Flower conſiſting of one Leaf, which is divided into three Parts, and is Funnel-ſhaped; the Embryo's are produced in the Tubercles; theſe afterwards become a fleſhy Fruit full of Juice; the Seeds which are lodged in the Tubercles are very ſmall, and almoſt Kidney-ſhaped.

The *Species* are;

1. ANANAS *aculeatus, fructu ovato, carne albida. Plum.* Oval-ſhaped Pine-Apple, with a whitiſh Fleſh.
2. ANANAS *aculeatus, fructu pyramidato, carne aurea. Plum.* Pyramidal Pine-Apple, with a yellow Fleſh.
3. ANANAS *folio vix ſerrato. Boerh. Ind. Alt.* 2. 83. Pine-Apple with ſmooth Leaves.
4. ANANAS *lucide virens, folio vix ſerrato. Hort. Elth.* Pine-Apple with ſhining green Leaves, and ſcarce any Spines on their Edges.
5. ANANAS *aculeatus, fructu pyramidato vireſcente, carne aurea.* The green Pine-apple, with a pyramidal Fruit, commonly called the Sugar-loaf Pine in *Barbadoes*.
6. ANANAS *fructu ovato ex luteo vireſcente, carne lutea.* The Olive-colour'd Pine.

There are ſeveral other Varieties of this Fruit, ſome of which may have been obtain'd from Seeds; and I doubt not but if the Seeds were ſown frequently, in the Countries where they are in Plenty, there may be as great Variety of theſe Fruit, as there are of Apples or Pears in *Europe*.

This Fruit (which is juſtly eſteemed for the Richneſs of its Flavour, as it ſurpaſſes all the known Fruits in the World) is produced from an herbaceous Plant, which hath Leaves ſomewhat reſembling thoſe of an *Aloe*, and are, for the moſt part, ſawed on their Edges, but are much thinner, and not ſo juicy as the *Aloe*: The Fruit reſembles the Cones of the *Pine-Tree*, from whence it is ſuppoſed to have its Name.

Where this Plant is a Native, I believe it is hard to determine; but it is probably an indigenous Plant in *Africa*, where, I have been informed, they grow in uncultivated Places in great Plenty. They have been long cultivated in the hotteſt Iſlands of the *Weſt Indies*, where they are in great Plenty and extraordinary Goodneſs; but it hath been very lately that it was introduced into the *European* Gardens, ſo as to produce Fruit: The firſt Perſon who ſucceeded in this Affair, was Monſieur *Le Cour* of *Leyden* in *Holland*, who, after a great many Trials with little or no Succeſs, did, at length, hit upon a proper Degree of Heat and Management, ſo as to produce Fruit equally as good (tho' not ſo large) as thoſe which are produced in the *Weſt Indies*, as hath been often affirm'd by Perſons who have lived many Years there: And it is to this worthy Cultivator of Gardening, who did not ſpare any Pains or Expence to accompliſh it, that all the Lovers thereof are obliged, for introducing this King of Fruits amongſt them; and it was from him that our Gardens in *England* were firſt ſupplied; tho' we have ſince had large Quantities brought from *America*. I can't here avoid taking Notice of a common Error which prevails amongſt many People, which is, that the Plants brought from *America* are not ſo good as thoſe which came from Mr. *Le Cour*; but it is a great Miſtake; for were the People who ſent over theſe Plants from *America* careful to ſend the beſt Kinds, there would be found many better Kinds than thoſe cultivated by Mr. *Le Cour*, who had his from thence at firſt, as his Gardener aſſured me; and I have ſeen as good Fruit produced from *American* Plants, as any I have yet ſeen, and ſome much larger than any I ſaw in Mr. *Le Cour*'s Garden.

The firſt Sort is the moſt common in *Europe*, but the ſecond Sort is much preferable to it, the Fruit of this being larger, and much better flavour'd; the Juice of this Sort is not ſo aſtringent as is that of the firſt, ſo that this Fruit may be eaten in greater Quantity, with leſs Danger. This Sort generally produces ſix or ſeven Suckers, immediately under the Fruit, whereby it may be increaſed much faſter than the common Sort; ſo that in a few Years it may be the moſt common Sort in *England*.

The third Sort is preſerved by ſome curious Perſons, for the ſake of Variety, but the Fruit is not near ſo good as either of the former. The fifth Sort is at preſent the moſt rare in *Europe*; there being very few of the Plants at preſent: This is eſteemed the beſt Sort yet known, by ſome of the moſt curious Perſons in *America*, who have thrown out all the other Sorts from their Gardens, and cultivate only this Kind. The Plants of this Sort may be procured from *Barbadoes* and *Mountſerrat*, in both which Places it is cultivated. The ſixth Sort was brought from *Jamaica*, this is not very common in *England* as yet; it is eſteemed a very good flavoured Fruit by thoſe Perſons who have taſted it; but it being a very backward Sort, will render it leſs valuable in our Climate; for this Sort will require a Month longer time to ripen, from the firſt Appearance of the Fruit to its Maturity, than moſt of the other Sorts. I have alſo heard of another Kind of Pine, whoſe Fleſh is very green, and the Outſide yellow; but having never ſeen the Sort, I cannot give any Account of it. There are many other Kinds to be found in the ſeveral Countries where they are cultivated, which have ariſen from Seeds, which differ in their Shape, Colour, and the Flavour of their Fruit; ſo that as theſe Fruits become common in *Europe*, all the bad Sorts ſhould be rejected, and ſuch only as produce fine Fruit ſhould be cultivated.

The Sort with very ſmooth Graſs-green Leaves, was raiſed from Seeds taken out of a rotten Fruit, which came from the *Weſt Indies*, to the late *Henry Heathcote*, Eſq; from whom I received one Plant, which hath produced large Fruit; this, I am told, is what the People of *America* call the *King-Pine*.

Theſe Plants are propagated by planting the Heads which grow upon each Fruit, or by Suckers produced from the old Stems, which muſt be planted in Pots about five or ſix Inches over at Top, fill'd with good freſh light Earth, mix'd with a very little rotten Dung, which muſt be often turn'd, to mix them the better together, giving them a little Water to ſettle the Earth to their Roots; then plunge them into a well-temper'd Bed of Tanners Bark. For the Manner of making theſe Beds, I ſhall refer to you to the Article of *Hot-beds*.

Take care to give them frequent but gentle Refreſhings with Water, and if your Bed ſhould decline its Heat, it will be very proper to add a little freſh Bark thereto, which muſt be mixed with the old, and will cauſe it to ferment again, and increaſe the Heat of your Bed.

Obſerve alſo, as the Nights grow cold in *Auguſt* and *September*, to increaſe your Covering over the Glaſſes, that by this means your young Plants may be furniſhed with ſtrong Roots before Winter: Toward the latter End of *October*, you muſt remove theſe Plants out of the Bark-bed into the Stove, (eſpecially thoſe Plants that are ſtrong enough to produce Fruit the next Year) diſpoſing them regularly on the Stands, ſo as not to crowd each other, nor their Leaves to interfere, if you have Room enough in your Stove to prevent it.

During the Winter Seaſon, you muſt obſerve to keep the Stove to a good Temper of Heat, (never ſuffering the Spirit in the Thermometer to fall below the Degree of Heat, which is aſſigned them on Mr. *Fowler*'s Botanical Thermometers;) nor ſhould the Spirit be ever raiſed much above five Degrees more; for too great a Heat would forward their Fruiting too much, and Cold would prevent it for that Seaſon, ſo that the middle Degree of Heat is beſt: Forget not to refreſh them with Water (which ſhould be placed in the ſame Stove at leaſt twenty-four Hours before uſed, that the Cold may be taken off) at leaſt once a Week, or oftener, according to the Temper of your Stove, or as you find the Earth in the Pots to require it.

Your Plants thus managed, will, by the Beginning of *February*, or ſoon after, ſhew their Bud for Fruit in the Center of the Plant, and muſt therefore be diligently kept forwarded by gently increaſing the Heat of the Stove, and often repeating your Watering: In the Middle of *February*, you muſt prepare your Tan for the Hot-bed, which ſhould be made at leaſt a Month before the Plants are ſet into it, that the great Heat of the Bed may be paſs'd, which would be ſubject to burn the extreme Parts of the Roots, and thereby give ſo great a Check to the Plants, as not to be recovered again in two Months; and this very often ſpoils the Fruit, by retarding the Growth of the Plant; ſo that whenever they begin to recover their Vigour, that Nouriſhment which ſhould have been employed to increaſe the Bulk of the Fruit, is all ſpent in furniſhing a large Top or Crown to a ſmall inſignificant Fruit.

Toward the Middle or latter End of *March* (according as you find the Bed in Temper, or the Weather favourable) you may remove your Plants into the Bark-bed, (plunging the Pots at firſt but half way into the Bark) that the ſudden Heat to their Roots may not be violent; but obſerve to keep your Glaſſes cover'd in bad Weather and in the Night, that you may preſerve a conſtant warm Air in the Bed; and if it ſhould happen to prove very hot in the Day, give them a little Air by raiſing the Glaſſes with a ſmall Stone; and if the Sun ſhould ſhine very hot upon the Glaſſes, it will be adviſable to ſhade them, in the Middle of the Day, from the Violence thereof, which (eſpecially at their firſt coming out of the Stove) would alter and change the Colour of the Plants, and be very prejudicial to them.

In about three Weeks, or a Month's time, after your Plants were ſet into the Bark, you may raiſe them up again, and ſtir the Surface of the Bark with a ſmall Dung-fork, and plunge the Pots down to their Rims therein; for by this time there will be no Danger of hurting their Roots with Heat; and obſerve to give them frequent Waterings, as they ſhall require it; and at this time you may ſhift ſuch of your Plants as do not fruit, into larger Pots (if they require it); and if you ſtir up the Earth on the Surface of the Pots where there is Fruit, and take it out with your Hands, filling them up again with good freſh Earth, it will be of great Service to your Fruit; but have a care, in this Operation, not to let any Earth in amongſt the Leaves of the Plant, nor to diſturb the Roots too much, both which will be hurtful to them.

During the Summer Seaſon, give them frequent Waterings, and ſhade them from the Violence of the Sun in very hot Days, and give them Air, by raiſing the Glaſſes in proportion to the Warmth of the Bed, and Heat of the Weather; and if you find your Bed grow cold, you muſt ſtir up the Bark with a Dung-fork almoſt to the Bottom, looſening and breaking the Lumps; and if you add a little freſh Bark to it, it will increaſe the Heat, and then plunge the Pots into it again: This may be repeated two or three times in a Summer, according to the Temper of the Bed, by which Means your Plants will be always kept in a growing State. Theſe few Rules, if rightly obſerved will, I doubt not, afford the Practitioner Succeſs. As for the Contrivance of *Stoves*, I ſhall refer the Reader to the Article on that Subject, where he will be furniſhed with their ſeveral Deſcriptions.

The Time of this Fruit's ripening is, from the Beginning of *July* till the End of *September*; after which Time, the Fruits that ripen are ſeldom well taſted, the Seaſon being ſo far ſpent, that we have not Heat enough to correct the Crudities, which are imbibed in the long Nights, from the Vapours of the Bed, and their own Perſpiration in the Day-time.

The manner of judging when they are mature, is, by the ſtrong Smell they emit like that of ripe Fruits, and by gently preſſing the Protuberances of the Fruit with your Thumb and Finger; and if they give Way, it is a certain Sign of Ripeneſs: nor will this Fruit keep above three or four Days at moſt, if ſuffer'd to remain on the Plant, before its high Flavour will be loſt; and if cut, it ſhould not be kept above twenty-four Hours at moſt, if you would eat it in Perfection; but if you would keep them back a little time, you ſhould do it before they are quite ripe, or ſoon after they begin to change the Colour; which may be effected by allowing them a greater Share of Air in the Day-time, and by ſcreening the Glaſſes with Mats in the Heat of the Day.

This Fruit ſhould be ſerved up to Table intire, (without breaking off the Crown, as is by ſome practiſed) which greatly ſpoils the high Flavour of the Fruit, by letting out a Part of its Juice, and by opening the Fruit to imbibe the moiſt Particles floating in the Air of the Place where it is kept, which greatly flattens that delicate Poignancy, which is always found in a freſh kindly Fruit of this Sort.

When the Fruit is to be eat, you may take the Stalk thereof in one Hand, and the Crown of the Fruit in the other, and by gently twiſting it, they will readily part, and the Crown will come out more intire, and fit for planting, than if cut off, and the Fruit will be leſs injured: Then you may cut it into tranſverſe Slices, in proportion to the Company that is to eat of it, laying them ſingly on a Plate; the outſide Coat muſt be pared off, as in many other Fruits, which would be troubleſome in eating; the Inſide of a good Fruit will cut almoſt as firm as a Nectarine, and is of a moſt delicious Flavour, and very full of Juice, and is juſtly termed the King of Fruits.

It hath been the Practice of moſt People who have cultivated this Fruit in *Europe*, to make their Hot-beds in Frames about three Feet deep; but it is a much better Method to have a Stove on purpoſe for this Fruit, with Bark Pits in it, for the Hot-bed: theſe Stoves need not be higher than to admit of a Perſon's walking upright on the Backſide; and in Front the Glaſſes may ſlope down within ſix Inches of the Bark. In ſuch a Stove as this, there will be a much greater Share of Air than in the low Frames, ſo that the Plants will thrive much better, and the Fruit will have a higher Flavour. The Manner of contriving theſe Stoves ſhall be fully explained under the Article *Stove.*

I have above given full Directions for the cultivating this excellent Fruit in *England*; I ſhall now add a few Inſtructions founded on later Obſervations; as alſo Directions how to manage ſuch as are infeſted with Inſects, which often totally deſtroy the Plants, or at leaſt weaken them ſo much, as not to be recovered in leſs than a Year, tho' managed with the greateſt Skill. And, Firſt,

As to the Earth in which theſe ſhould be planted, if you have a rich good Kitchen Garden Mould, not too heavy, ſo as to detain the Moiſture too long, nor over-light and ſandy, it will be very proper for them without any Mixture; but where this is wanting, you ſhould procure ſome freſh Earth from a good Paſture, which ſhould be mixed with about a third Part of rotten Neats-dung, or the Dung of an old Melon or Cucumber-bed, which is well conſumed. Theſe ſhould be mixed two or three Months at leaſt before they are uſed, and ſhould be often turned, that their Parts may be the better united, as alſo the Clods well broken. This Earth ſhould not be ſcreened very fine, for if you only clear it of the great Stones, it will be better for the Plants, than when it is made too fine. You ſhould always avoid mixing any Sand with the Earth, unleſs it be extremely ſtiff, and then it will be neceſſary to have it mixed at leaſt ſix Months before it is uſed, and it muſt be frequently turned, that the Sand may be incorporated in the Earth, ſo as to divide its Parts; but you ſhould not put more than a ſixth Part of Sand, for too much Sand is very injurious to theſe Plants.

In the *Summer* Seaſon, when the Weather is warm, theſe Plants muſt be frequently watered, but you ſhould not give to them large Quantities at each Time, you muſt alſo be very careful that the Moiſture is not detained in the Pots, by the Holes being ſtopp'd, for that will ſoon deſtroy the Plants. If the Seaſon is warm, they ſhould be watered every other Day, but in a cool Seaſon twice a Week will be often enough; and during the *Summer* Seaſon, you ſhould once a Week, water them gently all over their Leaves, which will waſh the Filth from off them, and thereby greatly promote the Growth of the Plants.

There are ſome Perſons who frequently ſhift theſe Plants out of the Pots, but this is by no means to be practiſed by thoſe who propoſe to have large well-flavoured Fruit; for unleſs the Pots be filled with the Roots, by the time the Plants begin to ſhew their Fruit, they commonly produce ſmall Fruit, which have generally large Crowns on them. So that the Plants will not require to be new potted oftener than twice in a Seaſon; the firſt Time ſhould be about the End of *April*, when the Suckers and Crowns of the former Years Fruit (which remained all the *Winter* in thoſe Pots in which they were firſt planted) ſhould be ſhifted into larger Pots, *i. e.* thoſe which were in half-penny or three-farthing Pots, ſhould be put into Penny or at moſt three-half-penny Pots, according to the Size of the Plants; for you muſt be very careful not to over-pot them, nothing being more prejudicial to theſe Plants. The ſecond Time for ſhifting of them is, toward the latter End of *Auguſt*, or the Beginning of *September*, when you ſhould ſhift thoſe Plants which are of a proper Size for fruiting the following *Spring*, into two-penny Pots, which are full large enough for any of theſe Plants. At each of theſe Times of ſhifting the Plants, the Bark-bed ſhould be ſtirred up, and ſome new Bark added, to raiſe the Bed up to the Height it was at firſt made; and when the Pots are plunged again into the Bark-bed, the Plants ſhould be watered gently all over their Leaves, to waſh off the Filth, and to ſettle the Earth to the Roots of the Plants. If the Bark-bed be well ſtirred, and a Quantity of good freſh Bark added to the Bed, at this latter ſhifting, it will be of great Service to the Plants, and they may remain in the Tan, until the Beginning of *November*, or ſometimes later, according to the Mildneſs of the Seaſon, and will not require any Fire before that time. During the *Winter* Seaſon theſe Plants will not require to be watered oftener than every third or fourth Day, according as you find the Earth in the Pots to dry; nor ſhould you give them too much at each time, for it is much better to give them a little Water often, than to over-water them, eſpecially at that Seaſon.

You muſt obſerve never to ſhift thoſe Plants which ſhew their Fruit, into other Pots, for if they are removed after the Fruit appears, it will ſtop the Growth, and thereby cauſe the Fruit to be ſmaller, and retard its ripening, ſo that many times it will be *October* or *November* before the Fruit is ripe. Therefore you ſhould be very careful to keep the Plants in a vigorous growing State, from the firſt Appearance of the Fruit, for upon this depends the Goodneſs, and Size of the Fruit; for if they receive a Check after this, the Fruit is generally ſmall, and ill-taſted.

When you have cut off the Fruit from the Plants, whoſe Kind you are deſirous to propagate, you ſhould trim the Leaves, and plunge the Pots into a moderate Hot-bed, obſerving to refreſh them frequently with Water, which will cauſe them to put out Suckers in Plenty, ſo that a Perſon may be ſoon ſupplied with Plants enough of any of the Kinds, who will but obſerve to keep their Plants in Health.

There is not any thing which can happen to theſe Plants, of a more dangerous Nature, than to have them attacked by ſmall white Inſects, which appear at firſt like a white Mildew, but ſoon after have the Appearance of Lice; theſe attack both Root and Leaves at the ſame time, and if they are not ſoon deſtroyed, will ſpread over a whole Stove in a ſhort time; and in a few Weeks will entirely ſtop the Growth of the Plants, by ſucking out the nutritious Juice, ſo that the Leaves will appear yellow and ſickly, and have generally a great Number of yellow tranſparent Spots all over them. Theſe Inſects, after they are fully grown, appear like Bugs; and adhere ſo cloſely to the Leaves, as not to be eaſily waſh'd off, and ſeem, as if they had no Life in them. They were originally brought from *America* upon the Plants which were brought from thence, and I believe they are the ſame Inſects which have deſtroyed the Sugar-Canes of late Years, in ſome of the *Leeward* Iſlands. Since they have been in *England*, they have ſpread greatly in ſuch Stoves, where there has not been more than ordinary Care taken to deſtroy them. They have alſo attacked the Orange Trees in many Gardens near *London*, and have done them incredible Damage, but I do not find they will endure the Cold of our Climate in Winter, ſo that they are never found on ſuch Plants as live in the open Air. The only Method I have yet been able to diſcover for deſtroying theſe Inſects, is, by waſhing the Leaves, Branches, and Stems, of ſuch Plants as they attack, frequently with Water, in which there has been a ſtrong Infuſion of Tobacco-ſtalks, which I find will deſtroy the Inſects, and not prejudice the Plants. But this Method cannot be practiſed on the *Ananas* Plants, becauſe the Inſects will faſten themſelves ſo low between the Leaves, that it is impoſſible to come at them with a Sponge to waſh them off; ſo that if all thoſe which appear to Sight are cleared off, they will ſoon be ſucceeded by a freſh Supply from below; and the Roots will be alſo equally infeſted at the ſame time. Therefore, where-ever theſe Inſects appear on the Plants, the ſafeſt Method will be, to take the Plants out of the Pots, and clear the Earth from the Roots; then prepare a large Tub, which ſhould be filled with Water, in which there has been a ſtrong Infuſion of Tobacco-ſtalks; into this Tub you ſhould put the Plants, placing ſome Sticks croſs the Tub, to keep the Plants immerſed in the Water. In this Water they ſhould remain twenty-four Hours, then take them out, and with a Sponge waſh off all the Inſects from the Leaves and Roots, which may be eaſily effected when the Inſects are killed by the Infuſion; then cut off all the ſmall Fibres of the Roots, and dip the Plants into a Tub of Fair Water, waſhing them therein, which is the moſt effectual way to clear them from the Inſects. Then you ſhould pot them in freſh Earth, and having ſtirred up the Bark-bed, and added ſome new Tan to give a freſh Heat to the Bed, the Pots ſhould be plunged again, obſerving to water them all over the Leaves, (as was before directed) and this ſhould be frequently repeated during the Summer Seaſon; for I obſerve theſe Inſects always multiply much faſter where the Plants are kept dry, than in ſuch Places where the Plants are duly watered, and kept in a growing State. And the ſame is alſo obſerved in *America*, for it is in long Droughts that the Inſects make ſuch Deſtruction of the Sugar Canes. And in thoſe Iſlands where they have had ſeveral very dry Seaſons of late, they have increaſed to ſuch a Degree, as to deſtroy the greateſt Part of the Canes in the Iſlands, rendering them not only unfit for Sugar, but ſo poiſon the Juice of the Plant, as to render it unfit to make *Rum.* So that many Planters have been ruined by theſe Inſects.

As theſe Inſects are frequently brought over from *America* on the *Ananas* Plants, which come from thence, ſo thoſe Perſons who procure their Plants from thence, ſhould look carefully over them when they receive them, to ſee they have none of theſe Inſects on them; for if they have, they will ſoon be propagated over all the Plants in the Stove where theſe are placed; therefore, whenever they are obſerved, the Plants ſhould be ſoaked as was before directed, before they are planted into Pots.

It hath been the common Practice of moſt Perſons, who have cultivated this Fruit in *Europe*, to build dry Stoves in which they keep their Plants in Winter, placing the Pots on Scaffolds, (after the Manner in which Orange-Trees are placed in a Green-houſe) and in the Summer to keep them in Hot-beds of Tanners Bark under Frames; but this is found by late

Experience a bad Method ; for the Glaſſes lying ſo near over the Plants, there is not a ſufficient Quantity of Air in the Bed to nouriſh the Fruit, and give it that vinous Flavour which good Fruit always abounds with ; and when theſe Glaſſes are cloſely ſhut down in the Night, the Vapours which ariſe from the Fermentation of the Tan, and the Perſpiration of the Plants, are cloſely pent in, and being condenſed againſt the Glaſſes, fall in Water on the Plants.

Therefore, to remedy this Inconvenience, it is now the Practice of thoſe Perſons who are deſirous to propagate this Fruit, to erect low Stoves, with Pits therein for the Hot-bed, (after the manner of the Bark-ſtove deſcribed) but much lower ; for as theſe Plants do not grow above two Feet and a half, or at moſt three Feet, above the Pot in Height, ſo there is no Neceſſity for having theſe Stoves very high. Some Perſons build them with upright Glaſſes in Front, about four Feet high, and ſloping Glaſſes over theſe, which riſe about ſix Feet high, ſo that there is juſt Height enough for Perſons to walk upright, on the Back-ſide of the Bark-bed. Others make but one Slope of Glaſſes, from the Top of the Stove, down to the Plate, which lies about ſix or eight Inches above the Bark-pit, in the Front of the Stove. So that in this Stove there is no Walk made in the Front between the Bark-pit and the Glaſſes ; nor is it very neceſſary, where the Bark-pit is not above ſix Feet and a half wide ; for it will be eaſy to reach from the Walk on the Back-ſide of the Pit, to water the Plants in Front, with a Watering-pot that has a long Spout ; and when the Plants are to be ſhifted, or the Bark renewed, which is not done but in the Spring, or Summer Months, the Glaſſes may be taken down, and the Plants removed with Safety. One of theſe Stoves about twenty Feet long in the Clear, with the Pit for the Tan reaching from end to end, and ſix Feet and a half wide, will contain about a hundred Plants, ſo that whoever is deſirous to have this Fruit, may eaſily proportion their Stove to the Quantity of Fruit which they are willing to have.

But it will be alſo neceſſary to have a Bark-pit under a deep Frame, in order to raiſe the young Plants ; for in this Bed you ſhould plunge the Suckers, when they are taken from the old Plants, as alſo the Crowns which come from the Fruit ; ſo that this Frame will be as a Nurſery to raiſe the young Plants to ſupply the Stove. But theſe Plants ſhould not remain in theſe Frames longer than till the Beginning of *November*, at which time they muſt be removed into the Stove, and being ſmall, may be crowded in amongſt the larger Plants ; for as they will not grow much during the Winter Seaſon, ſo they may be placed very cloſe together. The Beginning of *March* you muſt remove theſe Plants out into the Hot-bed again, which ſhould be prepared a Fortnight before, that the Tan may have acquired a proper Heat ; but you ſhould be careful that the Tan be not too hot, for that might ſcald the Fibres of the Plants, if they are ſuddenly plunged therein. Therefore, if you find the Bark too hot, you ſhould not plunge the Pots above two or three Inches into the Tan, letting them remain ſo until the Heat of the Tan is a little abated, when you ſhould plunge the Pots down to their Rims in the Bed. If the Nights ſhould continue cold after theſe Plants are removed into the Bed, you muſt carefully cover the Glaſſes with Mats, otherwiſe by coming out of a warm Stove, they may receive a ſudden Check, which will greatly retard their Growth, which muſt be carefully avoided, becauſe the ſooner the Plants are ſet growing in the Spring, the more time they will have to gain Strength, in order to produce large Fruit the following Seaſon.

You ſhould not plunge the Pots too cloſe together in this Frame, but allow them a proper Diſtance, that the lower part of the Plants may increaſe in Bulk, for it is on this that the Magnitude of the Fruit depends ; for when the Plants are placed too cloſe, they draw up very tall, but do not obtain Strength, ſo that when they are taken out of the Bed, the Leaves are not able to ſupport themſelves ; but all the outward long Leaves will fall away, leaving the ſmaller middle Leaves naked ; and this ſometimes will cauſe them to rot in the Centre. You muſt alſo obſerve, when the Sun is very warm, to raiſe the Glaſſes of the Hot-bed with Stones, in order to let out the Steam of the Bed, and to admit freſh Air ; for one Neglect of this kind in a very hot Day, may deſtroy all the Plants, or at leaſt ſo ſcald them, that they will not get over it in many Months. It will alſo be very proper, in extreme hot Weather to ſhade the Glaſſes in the middle of the Day with Mats ; for the Glaſſes lying ſo near to the Leaves of the Plants will occaſion a prodigious Heat at ſuch Times.

There are ſeveral Perſons who let their *Ananas* Plants remain plunged in the Bark-bed in the Stoves all the Winter Seaſon ; but where this is practiſed, the Plants muſt not be watered ſo often, as thoſe which are placed on Boards during that Seaſon ; for the Moiſture which ariſes from the Bark, will preſerve the Bottom of the Pots from drying, ſo that a ſmall Share of Water will be ſufficient for theſe Plants. Others, who do not permit their Plants to remain in the Tan all the Winter, and have no dry Stove, raiſe their Pots out of the Bed, and level the Bark, then lay ſome old Boards on the Bark, upon which they place their Pots, in this Situation they let them remain until the Beginning of *March*, at which time they renew the Bark-bed in the Stove, and plunge the Plants therein. In renewing of the Bark at this Seaſon, it is not neceſſary to take all the old Bark out, one half of it will be ſufficient ; for the remaining half ſhould be ſtirred to the Bottom, and mixed with the new Tan, which will prevent it from being too hot. The Pits in theſe Stoves need not be more than two Feet and a half, for that will contain a ſufficient Quantity of Tan, to preſerve a Heat.

ANAPODOPHYLLON, [of *Anas*, *Lat.* a Duck, ποῦς, a Foot, and φυλλον, *Gr.* a Leaf] Duck's-foot, or *Pomum Maiale*, *i. e.* May-Apple.

The *Characters* are ;

The Cup of the Flower conſiſts of one Leaf ; the Flowers are hexapetalous ; the Foot-ſtalk of the Flower comes out from the Stalk of the Leaf ; the Fruit is in Shape of an Urn, in which are contained many roundiſh fimbriated Seeds.

This Plant was brought from *America*, and is by ſome of the Inhabitants call'd, Black Snake-root, and by others, the May-Apple ; I ſuppoſe, becauſe in that Month the Fruit of this Plant is nearly ripe, and is of an Oval Shape, in ſome meaſure reſembling a ſmall Apple. We have but one *Species* of this Plant in *England*, that I know of, which is,

ANAPODOPHYLLON *Canadenſe Morini. Tourn.* The *Canada* Duck's-foot of *Morin.*

This Plant is very hardy, enduring our ſharpeſt Winters in the open Ground : It is increaſed by parting the Roots in *Auguſt*, after the green Leaves decay : It loves a moderate dry Soil, and for the Oddneſs of the Plant, may merit a Place in a good Garden, altho' it is of no great Beauty.

ANATOMY, ['Ανατομία, of 'Ανατέμνω, *Gr.* to diſſect] A Diſſection.

Anatomy of Plants is a cutting, dividing, or ſeparating the Parts or Members of Plants, in order to diſcover the Size, Form, Structure, and Uſes of their ſeveral Veſſels, for the better promoting their Culture.

Anatomiſts have obſerved a great Similitude betwixt the mechanick Frame of Plants and Animals : The Parts of Plants ſeeming to bear a conſtant Analogy to thoſe of Animals ; and the Oeconomy, both Vegetable and Animal, ſeem to be formed on the ſame Model.

The Parts of a Plant are the *Root*, the *Wood*, the *Bark*, and the *Pith*.

1. The *Roots* of the Plants are ſpongeous Bodies, whoſe Parts are diſpoſed for the eaſy Admittance of certain humid Particles, which are prepared in the Ground. The Quality of the Root is found much to depend upon the Size of its Veſſels and Pores.

Monſieur *Renaume* ſuppoſes the *Root* of a Plant to do the Office of all the Parts in the *Abdomen* of Animals, which ſerve to Nutrition, as the Stomach, Inteſtines, &c.

Dr. *Boerhaave* conſiders the *Roots* of Plants to be compoſed of a number of abſorbent Veſſels, which are analogous to the *Lacteals* in Animals.

The *Root*, according to Dr. *Van Royen*, is that Part of the Plant by which the Nutriment is taken in, or that by which the Aliment is attracted, as *Theophraſtus* has defined it : but it is not all that Part, which is committed to the Earth, to be nouriſhed by the Matter that is about it, which is properly to be call'd the Trunk of the Root ; this is to be referr'd rather to the Stalk or Stem, than to the Root, in that it conſiſts of the ſame implicated Kinds of Veſſels ; but that Part that is by its Surface contiguous to the exterior Matrix, which being perforated with infinite little Mouths, promotes the received Moiſtures, that they may be afterwards carried, by Veſſels not unlike to the Lacteal ones, into the very Body of the Plant ; this is properly to be called the *Root.*

Which Definition, altho' it may ſeem too ſtrict, is the moſt general and applicable to all Plants ; for it agrees as well with them which have no Root, as the vulgar Opinion is, as to thoſe which have a manifeſt Root : Of the former Kind, there are but very few Plants, but of the latter a great many.

As to thoſe that want a manifeſt Root, the Superficies of them is found to be perforated on all Sides with very ſmall

Holes, by which they take in their Nutriment, as in the *Pomo Aurantio*, call'd *Nepthuni*, or *Pila Marina* by Fiſhermen, and ſo in theſe the whole Superficies ſerves for Roots; as is plainly ſeen in ſome ſtony Plants that grow under the Sea, and may be in ſome ſort proved to be deduced from the Analogy of Animals; for theſe being become *ſui generis*, do take in Aliment, not only by the Mouth, but alſo the whole Skin expoſed to the moiſt Air, ſeems to ſerve to the ſame Deſign.

But thoſe Plants that are endued with a conſpicuous Root, and more obvious to the Senſes, differ among themſelves very much in this Part; for ſome are bulboſe, ſome are ſquamoſe, or tuberoſe, others grumoſe, others fibroſe, and laſtly, others nodoſe; which as it will be ſufficient to have taken Notice of the primary Differences of Roots, I ſhall omit their particular Definition in this Place, but refer them to their ſeveral Heads, where each of them ſhall be particularly deſcribed.

The firſt Part of the Root, which is call'd the *Epidermis* or *Cuticle*, is, for the moſt Part, of a brown or duſky Colour, is very thin, and is eaſily peel'd off from the under Skin, (if it be firſt ſoak'd in warm Water) which being viewed by a Microſcope, ſhews its moſt tender Structure much like a Net, pierced thro' with many ſmall Holes. And theſe little Orifices of the *Epidermis* being dilated, and filled with the received Moiſture, reſemble Veſicles, which being exhauſted yearly by the Mutation of the Air, become conſolidated and periſh; to wit, this being driven out by a new Cuticle growing under it, after the ſame manner as ſquammigerous Animals do annually caſt the old *Epidermis*, a new Cuticle coming under it, ſo that theſe little Veſſels, Fibrils, or by what Name ſoever they are call'd, may not unfitly be compared to the Veins of Animals.

But the other Part, which on the Outſide conſtitutes the *Cortex* or outer Bark, and on the Inſide the *Liber* or inner Bark is call'd *Cutis*; in which there are Parts to be conſidered of a four-fold Kind:

1. Certain ſtrong Fibres, cohering and elaſtick, ſtretched out vertically with the lateral Fibres communicating among themſelves, and compacting [or thruſting in] the former, they form a hollow Cylinder or Zone under the *Epidermis*; and this hath another under it, which alſo includes a third, and ſo of the reſt to the moſt inward of all, which luxuriates near the Wood, and is by a peculiar Name called *Liber*, or Inward Bark.

And theſe Zones or Girdles, altho' they are moſt innumerable, may all be peel'd off as the *Lamellæ* of Bulbs: and inaſmuch as thoſe Fibres in the harder Roots of Trees are almoſt of a bony Nature, they procure a Firmneſs to the Cortex or outward Bark: And theſe Fibres are in all Plants, and appear as well in Graſs as in the Cedar-tree, altho' they are more compact in Trees than in Plants of a tenderer Structure, which are more eaſily ſuſtained.

2. In the Areas [or Spaces] which are between the Fibres and their Anaſtomoſes, there are every where membranaceous Veſſels full of Moiſture, or little Utricles, which, in the *Areæ*, or intercepted Spaces that are of a different Figure, are found to be various, and accommodated to all the Spaces: But all theſe Utricles communicate among themſelves, as is beſt ſeen in the greater Celandine, when we ſqueeze out that golden-coloured Liquor with which it is filled; and the middle Spaces betwixt theſe Zones have like Utricles, and ſo all the Fibres conſtitute hollow Canals, but the Utricles have receptacles communicating among themſelves.

3. Aerial Veſſels, or *Tracheæ*, are open from the lower to the upper Part of the Plant, and are twiſted or curled after an admirable manner, and diſpoſed round about with Fibres and Utricles in Form almoſt of a ſpiral Line, which in their Cavities contain an elaſtick Air; which being affected by the external Air, firſt expanded and afterwards condenſed, will be changed after a like manner, and feel the ſame Viciſſitudes of Cold and Heat, and ſo will undergo a reciprocal Motion of Cold and Heat. This Action is exerted in the Veſſels fill'd with Moiſture, which, when they cannot be condenſed, give Place, and are driven to thoſe that are higher, and are moved forward.

4. Laſtly, beſides Fibres, Utricles, and *Tracheæ*, a peculiar Kind of Veſſels appear, containing the Moiſtures, as it ſeems, ſecreted by the organical Diſpoſition of the Plant itſelf, which water [or moiſten] not only the *Cortex*, but the Wood, and the reſt of the Parts of Vegetables, and are turgid with a concocted Juice, which ſeems far more elaborate than is the Moiſture contained in the Fibres or Utricles; and the Mouths of theſe Veſſels being of a different Figure, pour forth ſometimes a various Liquor according to its peculiar Nature, chiefly near the outward Region of the *Cortex*: So the *Tithymalus* and *Cichory* do commonly diſtil a milky Humour; and the Cypreſs, Firr, and Pine, a certain Species of Turpentine.

And by how much theſe Circles are more outwards, by ſo much the middle Spaces between the two Zones are greater, and ſo are leſſened always towards the more inward in a certain Proportion, which ſeems to depend on this; *viz.* the outward Air acting on all Sides with an equal Preſſure, and ſo by a certain Power, preſſes the firſt or outward Zone, which by the ſame Power preſſes the ſecond; and this alſo by this Means is preſſed by its own condenſed Air, and preſſes together thoſe which are more inward, becauſe it cannot exert its Force upon the external Air: Therefore the ſecond Circle is neceſſarily more compreſſed than the firſt; and again, the third more than the ſecond, and ſo of the reſt: And the Utricles placed between the Circles are preſſed by the ſame Proportion, which by degrees are more and more exhauſted; thence the inner Circle loſes moſt of all the compreſſed and condenſated Utricles, and by degrees grows ſolid.

And this is properly call'd *Liber*, [the inward Bark] and is that Circle, which being middlemoſt by Place, and by Nature between the *Cortex* [or outward Bark] and the Wood, comes neareſt to the Nature of the Wood, and in time paſſes into it: for the *Cortex* loſes every Year one ſuch Circle, and becomes Wood, which may be diſtinguiſhed from the former Circles of the Root, Stock, or Trunk; and if they are cut horizontally, will ſhew the Number of ſuch Circles, and ſo how many Years the Tree is old.

And this ſucceſſive Mutation of the *Cortex* into *Liber*, and of *Liber* into Wood, is like to that we obſerve in the human Body in the Beginning of a *Callus*; for a *Callus* conſiſts of Skin, but ſo compreſſed, that all the Veſſels are loſt, and that Skin being become ſolid, is increaſed and grows to a greater Bulk.

But beſides theſe hitherto deſcribed, there occur certain peculiar Veſſels (of which Mention has been made in deſcribing the *Cortex*) which are found full of Turpentine, Gum, or a certain concreted Juice proper to them, the conſtant Progreſs of which is not very conſpicuous in all of them, by reaſon of the Tranſparency of the Moiſture.

5. The fifth and laſt Part is the moſt inward; the *Medulla* or Pith, diſpoſed in the middle Center of the Root; and as it ſeems different from the former, ſeeing this is ſometimes waſted, and that never, this appears more fungous, that more durable.

As to the Manner of the Root's performing its Function, it may be obſerved, that the Root having imbibed the ſaline and aqueous Juices of the Earth, and ſaturated itſelf with them, for the Nouriſhment of the Tree, thoſe Juices are put into Motion by Heat; which having enter'd the Mouths of the arterial Veſſels from the Root, they mount to the Top with a Force anſwerable to what ſets them in Motion; and by this means they gradually open the minute Veſſels roll'd up, and expand them into Leaves.

2. The *Wood*: This is conſider'd as conſiſting of *capillary Tubes*, running parallel from the Root throughout the Stalk: Some call the *capillary Tubes*, *arterial Veſſels*, becauſe the Sap riſes from the Root thro' theſe. The Apertures of theſe Tubes are, for the moſt part, too minute to be perceived by the bare Eye, unleſs in a Piece of Charcoal, Cane, or the like.

Wood, ſays Dr. *Grew*, by Microſcopical Obſervations, appears to be only an Aſſemblage of infinitely minute Canals or hollow Fibres; ſome of which ariſe from the Root upwards, and are diſpoſed in Form of a Circle; and the others, which are call'd *Inſertions*, tend horizontally from the Surface to the Center, ſo that they croſs each other, and are interwoven like the Threads of a Weaver's Web.

Beſides the *capillary Tubes*, &c. before-mentioned, there are other larger Veſſels, which ſome call *venal Veſſels*, which are diſpoſed on the Outſide of the *arterial Veſſels*, between the Wood and the inner Bark, and lead down to the Covering of the inward Root: Theſe Veſſels are ſuppoſed to contain the liquid Sap found in Plants in the Spring, &c.

The Rev. Dr. *Hales* tells us, in his excellent Treatiſe of *Vegetable Staticks*, that in order to find whether there was any lateral Communication of the Sap and Sap Veſſels, as there is of the Blood in Animals, by Means of the Ramifications and lateral Communications of their Veſſels, he took a young Oak-Branch 7 or 8 Inches diameter, as its tranſverſe Cut, 6 Feet high and full of Leaves; and having cut a large Gap to the Pith 7 Inches from the Bottom, and of an equal Depth the whole Length, and alſo cut another Gap 4 Inches above that on the oppoſite Side, he ſet the End of the Stem in Water, and that in two Nights and two Days time it imbibed and perſpired 13 Ounces; while another like Oak-Branch, ſomewhat bigger than that, but with no Notches cut in its Stem, imbibed 25 Ounces.

From this, and many other Experiments he there mentions, he ſays, we ſee a moſt free lateral Communication of the Sap

and

ſo that you may have theſe Beauties continued for near two Months together, or ſometimes longer, if the Seaſon prove favourable.

Towards the Middle or latter End of *May*, the Leaves of your firſt blown Roots will decay; at which Time you muſt take them out of the Ground, clearing them from the decayed Stalks, and waſhing them, to take the Earth clean from the Roots, then ſpread them on a Mat in a dry ſhady Place, till they are perfectly dried, when you may put them up in Bags, and hang them out of the Reach of Mice or other Vermin, which will deſtroy many of the Roots, if they can come at them.

Obſerve alſo to take up the latter planted Roots ſo ſoon as their Leaves decay; for if they are ſuffered to remain long after in the Ground, and there ſhould fall ſome Showers of Rain, they would ſoon put forth freſh Fibres, and make new Shoots, when it would be too late to remove them: At the Time when you take up the Roots, is the proper Seaſon for breaking or parting them, which may be done by ſeparating thoſe that you would chuſe to make all poſſible Increaſe from, into as many Parts as you can conveniently, provided each one of them have a good Eye or Bud; but thoſe you intend to blow ſtrong, ſhould by no means be parted too ſmall, which greatly weakens their Flowering.

The principal Colours in *Anemonies* are, White, Red, Blue, and Purple, and theſe in ſome of them are curiouſly intermixed; but the moſt prevailing Colours amongſt our *Engliſh*-raiſed Anemonies, are White and Red; but of late we have received from *France* great Varieties of Blues and Purples, which are exceeding fine Flowers; we ſhould therefore obſerve, in planting the Roots, to diſtribute the different Colours, ſo as to make an agreeable Mixture of each in every Bed, which will greatly add to their Beauty.

But ſince all the fine Varieties of theſe Flowers were firſt obtained from Seeds, no good Floriſt, that hath Garden-Room, ſhould neglect to ſow their Seeds; in order to which, we ſhould provide ourſelves with a Quantity of good ſingle (or Poppy) Anemonies, as they are called, of the beſt Colours, and ſuch as have ſtrong Stems, large Flowers, and other good Properties; theſe ſhould be planted early, that they may have Strength to produce good Seeds, which will be ripe in three Weeks or a Month's time, after the Flowers are paſt, when you muſt carefully gather it, otherwiſe it will be blown away in a ſhort time, it being incloſed in a downy Subſtance; you muſt preſerve this Seed till the Beginning of *Auguſt*, when you may either ſow it in Pots, Tubs, or a well-prepared Bed of light Earth; in the doing of it you muſt be careful not to let your Seeds be in Heaps, to avoid which is a thing little underſtood, and is what I have been informed of by Mr. *Obadiah Lowe*, Gardener at *Batterſea*, who hath, for ſeveral Years, raiſed large Quantities of theſe Flowers from Seeds; his Manner is thus:

After having levelled his Bed of Earth, in which he intends to ſow his Seeds, he rubs the Seeds well between his Hands, with a little dry Sand, in order to make them ſeparate the better, then he ſows them as regularly as poſſible over the Bed; but as theſe Seeds will ſtill adhere cloſely together, he takes a ſtrong Hair-bruſh, and gently ſweeps over the whole Bed, obſerving not to bruſh off the Seeds; this Bruſh will ſo ſeparate the Seeds, if carefully managed, as not to leave any intire Lumps; then gently ſift ſome light Earth, about a quarter of an Inch thick, over the Seeds, and if it ſhould prove hot dry Weather, it will be adviſeable to lay ſome Mats hollow upon the Bed in the Heat of the Day, and now and then give them a little Water; but this muſt be given gently, leſt by haſtily watering you waſh the Seeds out of the Ground; but be ſure to uncover the Bed at all times when there are gentle Showers; and as the Heat of the Weather decreaſes, ſo may you begin to uncover your Bed.

In about two Months after ſowing, your Plants will begin to appear, if the Seaſon has proved favourable, or your Care in Management hath not been wanting, otherwiſe they many times remain a whole Year in the Ground. The firſt Winter after their appearing above Ground, they are ſubject to Injuries from hard Froſts, or too much Wet, againſt both of which you muſt equally defend them; for the Froſt is very apt to looſen the Earth, ſo that the young Plants are often turned out of the Ground, after which a ſmall Froſt will deſtroy them; and too much Wet often rots their tender Roots, ſo that all your former Trouble may be loſt in a ſhort time for want of Care in this Particular; nor do I know of any thing more deſtructive to theſe tender Plants, than the cold black Froſts and Winds of *February* and *March*, from which you muſt be careful to defend them, by placing a low Reed Fence on the *North* and *Eaſt* Sides of the Bed, which may be moveable, and only faſtened to a few Stakes to ſupport it for the preſent, and may be taken quite away as the Seaſon advances, or removed to the *South* and *Weſt* Sides of the Bed, to ſcreen it from the Violence of the Sun, which often impairs theſe tender Plants.

As the Spring advances, if the Weather ſhould prove dry, you muſt gently refreſh them with Water, which will greatly ſtrengthen your Roots; and when the green Leaves are decayed, if your Roots are not too thick to remain in the ſame Bed another Year, you muſt clear off all the Weeds and decayed Leaves from the Bed, and ſift a little more of the ſame prepared good Earth, about a quarter of an Inch thick over the Surface, and obſerve to keep them clear from Weeds during the Summer Seaſon, and at *Michaelmas* repeat the ſame Earthing; and if your Roots ſucceed well, many of them will flower the ſecond Year, when you may ſelect all ſuch as you like, by marking them with a Stick; but I would not have you deſtroy any of them until after the third Year, when you have ſeen them blow ſtrong, at which Time you will be capable to judge of their Goodneſs.

But if your Roots are too thick in the Seed-bed to remain, you muſt, ſo ſoon as their green Leaves are decayed, ſift the Earth of your Bed thro' a very fine Sieve, in order to get out the Roots, which can be no otherways found, as being ſmall, and ſo nearly the Colour of the Ground; but in doing of this, obſerve not to diſturb the Ground too deep, ſo as to endanger the burying any of the Roots; for notwithſtanding all your Care, many ſmall Roots will be left behind; therefore, ſo ſoon as you have ſifted your whole Bed, and taken out all the Roots you can find, you muſt level the Earth of your Bed again, and let it remain till next Year, when you will find a plentiful Crop of Roots come up again: The young Roots which you take up muſt be dried, as was directed for the old ones, but ſhould be planted again three Weeks before them, that they may increaſe in Strength, ſo as to flower ſtrongly the ſucceeding Year.

ANEMONOIDES, [of 'Ανεμώνη and εἶδος, *Gr. i. e.* the Form or Image of Anemone] Wood Anemony: *vulgo.*

The *Characters* are;

The Root is perennial, and for the moſt part grumoſe and creeping; the Leaves are finely cut, three of which, for the moſt part, ſurround the Stalk; it hath a ſingle Flower upon each Stalk, which conſiſts of many Leaves, and are expanded in Form of an Anemone, *having many* Stamina *or Threads in the Middle; the Seeds are collected into an oblong Head, and are in Shape like thoſe of the* Ranunculus, *having no Down adhering to them.*

The *Species* are;

1. ANEMONOIDES *flore albo. Boerh. Ind.* Wood Anemony with white Flowers.
2. ANEMONOIDES *flore ex purpura rubente. Boerh. Ind.* Wood Anemone with purpliſh red Flowers.
3. ANEMONOIDES *flore majore, intenſiore, cæruleo. Boerh. Ind.* Wood Anemone with large deep blue Flowers.
4. ANEMONOIDES *flore albo pleno. Boerh. Ind.* Wood Anemone with double white Flowers.
5. ANEMONOIDES *flore pleno purpureo. Boerh. Ind.* Wood Anemone with double purple Flowers.
6. ANEMONOIDES *flore pleno cæruleo majore.* Wood Anemone with large double blue Flowers.

The firſt of theſe Plants is found wild in the Woods in moſt Parts of *England*, the other Varieties I have gathered in great plenty, in the Wilderneſſes belonging to the Gardens at *Wimbleton* in *Surrey*, which were, probably, at firſt taken from ſome Woods in *England*; in this Place they increaſe ſo faſt, that the Surface of the Ground is covered with them in the Spring; and what is more remarkable, that there the large blue and double Sorts are the moſt common: Theſe Plants are very pretty Ornaments to Wilderneſs Quarters or ſhady Walks in the Spring of the Year, continuing a long Time in Flower, and by their agreeable wild Appearance, have a very pleaſing Effect to the Eye.

The beſt Seaſon for tranſplanting theſe Flowers is in *May*, when the Leaves are decaying; for if they are ſuffered to remain until the Leaves are quite gone, it will be very difficult to find their Roots, which are nearly the Colour of the Earth: If theſe Roots are permitted to remain in a Garden undiſturbed they will multiply exceedingly, and produce great Quantities of Flowers; but if they are often removed, it will deſtroy them; therefore they ſhould be planted in ſuch ſhady Parts of Wilderneſſes as are ſeldom digged.

ANEMONOSPERMOS, [of 'Ανεμώνη and σπέρμα, *Gr.* Seed, becauſe the Wind eaſily bears away the Seed.]

The *Characters* are;

It hath an hemiſpherical ſcaly Cup; the Flower is radiated like the Ragwort; *but the Seeds are copiouſly ſurrounded with a pappous Down, as are thoſe of* Anemone.

The *Species* are;

1. ANEMONOSPERMOS *Africana, folio Jacobææ, flore luteo, extus puniceo. Boerh. Ind.* The *African* Anemonoſpermos, with Leaves like Ragwort, and Flowers which are yellow within, and red on the Outſides.

2. ANEMONOSPERMOS *Africana, folio cardui benedicti, florum radiis intus albicantibus. H. A.* The *African* Anemonoſpermos, with Leaves like the Bleſſed Thiſtle, and the Rays of the Flower are white on the Inſide.

3. ANEMONOSPERMOS *Africana, folio Jacobææ tenuiter laciniato, flore aurantio pulcherrimo. Boerh. Ind.* The *African* Anemonoſpermos, with ſlender divided Ragwort Leaves, and fair Orange-colour'd Flowers.

4. ANEMONOSPERMOS *Africana, folio & facie Taraxaci incanis. Par. Bat. App.* The *African* Anemonoſpermos, with Leaves like Dandelion, but are hoary.

Theſe Plants were originally brought from about the *Cape of Good Hope*, into the curious Gardens in *Holland*, where they have been propagated, and from whence they have been diſtributed into the ſeveral Parts of *Europe*, where they are now growing.

They are propagated by planting Cuttings of them in a Bed of light freſh Earth, in any of the Summer Months, obſerving to ſhade them from the Heat of the Sun until they have taken Root, as alſo to refreſh them often with Water, and in ſix Weeks or two Months after planting, they will be rooted ſufficiently; at which Time you ſhould tranſplant them into Pots filled with the like freſh Earth, ſetting the Pots in a ſhady Place until the Plants are ſettled in their new Earth; after which Time you ſhould expoſe them to the open Air until the latter End of *October*, or later, according as you find the Weather is favourable, when you muſt remove the Pots into the Green-houſe, where they ſhould be placed as near the Window as poſſible, that they may have a good Quantity of free Air at all Times when the Weather is mild; nor ſhould they be over-hung by other Plants, which would occaſion them to take a Mouldineſs, and rot; you muſt alſo frequently refreſh them with Water, but give them but a little at each time during the Winter Seaſon; but in Summer they will require a greater Plenty, as alſo to be often repeated.

Theſe Plants being pretty hardy, are only hurt by great Froſts; they may therefore be kept in the ſame Houſe with *Myrtles*, and alſo expoſed in the Summer with them; they will require to be ſhifted out of their Pots twice every Year, *viz.* in the Beginning of *June*, and again in *Auguſt*: at which Time you ſhould cut off a good Quantity of the Roots round the Outſide of their Balls; (but be very careful not to ſhake the Earth intirely from their Roots) and at theſe Times you ſhould prune off the ſtraggling Branches, the better to form their Heads into a regular Figure, but do not ſhorten their Branches, for that would cut off their Flower-Buds.

The fourth Sort is annual, and therefore only to be propagated by Seeds, (which Way alſo the other Sorts may be increaſed, if we have good Seeds, which are but rarely obtain'd in *England*:) The Seeds ſhould be ſown on a moderate Hot-bed in the Spring; and when the Plants are come up, they ſhould be tranſplanted into Pots of freſh Earth, and plunged into another very moderate Hot-bed to bring them forward, and afterwards expoſed to the open Air by degrees: But the fourth Sort is very ſubject to be deſtroyed by ſmall Inſects, which prey upon the Plants; you ſhould therefore carefully waſh them off whenever they appear thereon.

The three firſt Sorts ſhould be frequently renewed from Cuttings; for when they grow old, they are very ſubject to decay in Winter, by which the Species are ſometimes loſt, where it hath been neglected to raiſe young Plants.

They are all very pretty Ornaments to a Green-houſe; for their Flowers are produced in almoſt every Month of the Year, which, together with the Diverſity of their Leaves, greatly adds to the Variety, when intermixed with other Plants.

ANETHUM, Dill: [Ἄνηθον, which ſome will have call'd ἀνίκητον, *i. e.* Invincible, , becauſe it excites an Appetite to Food; others of παρὰ τὸ ἀνωθέειν, from its quick Growth.]

The *Characters* are;

It hath a ſlender fibroſe annual Root: the Leaves are like thoſe of Fennel; the Seeds are oval, plain, ſtreaked, and bordered.

The *Species* are;

1. ANETHUM *hortenſe. C. B.* Common *or* Garden Dill.

2. ANETHUM *verum Pernambucenſe. Zan.* The true Dill of *Pernambucq*.

3. ANETHUM *ſegetum, ſemine minori. Virid. Luſit.* Corn Dill with leſſer Seeds.

The firſt of theſe Sorts is that which is cultivated for Uſe; the other two are Varieties, which are preſerved as Curioſities in Botanick Gardens.

Theſe Plants are propagated by ſowing their Seeds early in the Spring in light rich Earth, where they will come up and grow very ſtrong in a ſhort time, provided they have Room; therefore the better Way is, when the Plants are come up, to hough them out, as is practiſed for Onions, Carrots, *&c.* leaving the Plants about eight or ten Inches aſunder every Way, obſerving to keep them clear from Weeds; and when the Seeds begin to be formed, you ſhould cut up thoſe that are intended to be put into the Pickle for Cucumbers, leaving thoſe that are intended for the Uſe of the Seeds, until they are ripe; at which Time it ſhould be cut, and ſpread upon a Cloth to dry, and then beat out for Uſe: and if you let the Seeds fall upon the Ground, they will ariſe the next Spring without any Care, ſo that the Trouble of ſowing their Seeds may be ſpared.

ANGELICA, [of *Angelus*, ſo called, as ſome Quacks, *&c.* pretend, from the Angels, on account of its excellent Qualities; for it is pretended, when the Army of a certain Emperor was miſerably afflicted with the Plague, an Angel admoniſhed him in a Dream to make uſe of this Plant, by which means he ſaved his Army.]

The *Characters* are;

It hath winged Leaves, which are divided into large Segments: the Stalks are hollow and jointed; the Flowers (which grow in an Umbel upon the Tops of the Stalks) conſiſt of five Leaves, and are ſucceeded by two large channelled Seeds.

The *Species* are;

1. ANGELICA *ſativa. C. B.* Common *or* manured Angelica.

2. ANGELICA *ſylveſtris, major. C. B.* Greater wild Angelica.

3. ANGELICA *lucida, Canadenſis. Cornut.* Shining *Canada* Angelica.

4. ANGELICA *montana perennis, aquilegiæ folio. Tourn.* Mountain Perennial Angelica, with Columbine Leaves.

There are ſeveral other Species of this Plant, which are preſerved in the curious Botanick Gardens; but as there are at preſent no particular Uſes which theſe are applied to, ſo it would be needleſs to enumerate them here.

The Common Angelica delights to grow in a very moiſt Soil: The Seeds of this Plant ſhould be ſown ſoon after it is ripe; for if it is kept until the Spring, ſeldom one Seed in forty of it will grow. When the Plants are come up about ſix Inches high, they ſhould be tranſplanted at a large Diſtance; for their Leaves extend very wide: The beſt Place for this Plant is upon the Sides of Ditches, or Pools of Water, where being planted about two Feet aſunder, they will thrive exceedingly. The ſecond Year after ſowing, they will ſhoot up to flower; therefore if you have a mind to continue their Roots, you ſhould cut down theſe Stems in *May*, which will occaſion their putting out Heads from the Sides of the Roots, whereby they may be continued for many Years; whereas if they had been permitted to ſeed, their Roots would periſh ſoon after.

The Gardeners near *London* propagate great Quantities of this Plant, for which they have a great Demand from the Confectioners, who make a Sweet-meat with the tender Stalks of it, cut in *May*.

This Plant is alſo uſed in Medicine, as are alſo the Seeds; therefore where it is cultivated for the Seeds, there ſhould be new Plantations annually made to ſupply the Places of thoſe which die.

The ſecond Sort grows wild by the Ditches Sides in many Parts of *England*, and is rarely propagated in a Garden.

The other two Sorts may be propagated by ſowing their Seeds in the Manner as was directed for the common Sort, but ſhould be planted in a drier Soil.

ANGURIA; the Water-Melon.

The *Characters* are;

It hath trailing Branches, as the Cucumber or Melon, and is *chiefly*

chiefly diſtinguiſhed from the other cucurbitaceous Plants by its Leaf, which is deeply cut and jagged, and by its producing an eatable Fruit.

The *Species* are;

1. ANGURIA *citrullus dicta. C. B. P.* Common Water-Melon, called Citrul.
2. ANGURIA *Indica maxima. C. B. P.* The largeſt *Indian* Water-Melon.
3. ANGURIA *carne rubente, ſemine nigro majori. Inſt. R. H.* Water-Melon, with a red Fleſh, and large black Seeds.
4. ANGURIA *carne rubente, ſemine nigro minori. Inſt. R. H.* Water-Melon, with a red Fleſh, and ſmaller black Seeds.
5. ANGURIA *carne flaveſcente, ſemine nigro. Inſt. R. H.* Water-Melon, with a yellowiſh Fleſh, and black Seeds.
6. ANGURIA *fructu rotundo, carne rubente, ſemine rubro.* Water-Melon, with a round Fruit, having a red Fleſh, and red Seeds.
7. ANGURIA *triphyllos Americana, parvo fructu. Inſt. R. H.* Three-leav'd *American* Water Melon, with a ſmall Fruit.
8. ANGURIA *Americana, fructu echinato eduli. Inſt. R. H.* *American* Water-Melon, with a prickly eatable Fruit.

The ſix firſt-mentioned Sorts are cultivated in *Spain*, *Portugal*, *Italy*, and moſt other warm Countries in *Europe*; as alſo in *Africa*, *Aſia*, and *America*; and are by the Inhabitants of thoſe Countries greatly eſteemed for their wholeſome cooling Quality; but in *England* they are not ſo univerſally eſteemed, tho' ſome few Perſons are very fond of them. I ſhall therefore give Directions for the raiſing of theſe Fruits, ſo that ſuch Perſons as are willing to be at the Expence and Trouble of raiſing them, may not be at a Loſs for Inſtructions.

You muſt firſt provide yourſelf with ſome Seeds, which ſhould be two or three Years old; for new Seeds are apt to produce vigorous Plants, which are ſeldom ſo fruitful as thoſe of a moderate Strength. The beſt Sorts to cultivate in *England*, are the fourth and ſixth Sorts; and next to theſe are the firſt and fifth Sorts; for the ſecond and third Sorts produce very large Fruit, which ſeldom ripen in this Climate. Having provided yourſelf with good Seed, you ſhould prepare a Heap of new Dung the Beginning of *February*, which ſhould be thrown in a Heap for about eight Days to heat; then you ſhould make a Hot-bed for one ſingle Light, for which one good Load of Dung will be ſufficient; this Dung ſhould be well wrought in making of the Bed, and muſt be beaten down pretty cloſe with a Dung-fork, that the Heat may not be too violent, and of longer Continuance: When the Dung is thus laid, you ſhould cover it about four Inches thick, with good light Earth, and having ſpread it very even, you ſhould put the Frame and Glaſs over it, leaving it to warm, two Days before you put the Seeds into it, obſerving, if the Steam riſes pretty much, to raiſe up the Glaſs with a Stone, to let it paſs off. Then, if you find your Bed in proper Temper, you may ſow your Seeds therein in Drills, covering them over with Earth, about half an Inch. After this, if you find your Bed very warm, you muſt give Air in the Day-time by raiſing of the Glaſſes; but if the Bed is cool, you muſt cover it well with Mats every Night, as alſo in bad Weather. In four or five Days after, you muſt prepare another Hot-bed to receive theſe Plants, which will be fit to tranſplant in ten Days, or a Fortnight at moſt, after the Seeds are ſown; this Bed need not be very large, for a few of theſe Plants will fill a large Quantity of Frames, when they are planted out for good; and while the Plants are young, there may be a great Quantity kept in one Light; ſo that thoſe Perſons who raiſe early Cucumbers, and Muſk-Melons, may alſo raiſe theſe Plants in the ſame Bed; for two or three Lights will be ſufficient to raiſe Plants enough of all three Kinds, to ſupply the largeſt Families, until they are planted out for good. In the Management of theſe Plants while young, there is little Difference from the Directions given for raiſing Muſk-Melons, therefore I need not repeat it here. The chief Thing to be obſerved, is, to let them have a large Share of Air whenever the Weather will permit, otherwiſe the Plants will draw up weak, and be good for little. As theſe Plants will require two or three Hot-beds, to bring the Fruit to Perfection, ſo it will be the better way to put the Plants into Baſkets, as was directed for the raiſing of early Cucumbers; but you ſhould not plant more than two Plants in each Baſket, for if one of them lives, it will be ſufficient; therefore when both the Plants do ſucceed, you ſhould draw out the weakeſt and moſt unpromiſing of them, before they begin to put out their Side-ſhoots, otherwiſe they will entangle and render it difficult to be performed, without greatly injuring the remaining Plant.

The Baſkets in which theſe Plants are to be planted, need not be more than a Foot diameter, ſo that one Light will contain twelve of them; which will be ſufficient for thirty-ſix Lights, when they are planted out for good; for where the Plants are vigorous, one ſingle Plant will ſpread ſo far as to fill three Lights, and if they have not room, they ſeldom ſet their Fruit well.

Theſe Baſkets may remain in the Nurſery-beds, until the Plants have ſpread, and put out many Runners; for when the Heat of this Bed declines, it is ſoon revived by adding a proper Lining of warm Dung to the Sides of the Bed quite round; ſo that when they are taken out of this Bed, and placed in the Ridges where they are to remain, the Heat of theſe Beds will laſt ſo long as to ſet their Fruit, which is of great Conſequence; for when the Plants are ridged out very young, the Beds are generally made of a great Thickneſs in Dung, in order to continue their Heat, ſo that for ſome time after they are made, they are ſo extreme hot, as to endanger the ſcalding of the Plants: and by the time the Fruit begins to appear, there is little Heat left in the Beds, which often occaſions the Fruit to drop off and come to nothing.

After theſe Plants are placed in the Beds where they are to remain, you muſt carefully lead the Shoots as they are produced, ſo as to fill each Part of the Frame, but not to crowd each other; and be careful to keep them clear from Weeds, as alſo to admit freſh Air whenever the Weather will permit; they muſt alſo be frequently watered, but do not give it them in great Quantities. In ſhort, there is little Difference to be obſerved in the Management of theſe, from that of Muſk-Melons, but only to give them more room, and to keep the Beds to a good Temperature of Heat, without which theſe Fruit will ſeldom come to good in this Country.

ANIL; [is ſo called by the Inhabitants of all the different Countries where it grows] The Indigo Plant.

The *Characters* are;

It hath pennated (or winged) Leaves, which are terminated by a ſingle Lobe at the Extremity; the Flowers (which are for the moſt part diſpos'd in a Spike) conſiſt of five Leaves, and are of the Papilionaceous *Kind, the uppermoſt Petal (or Standard) being larger than the others, and is rounder and lightly furrow'd on the Side; the lower Leaves (or Petals) are ſhort, and terminate in a Point: In the Middle of the Flower is ſituated the Style, which afterwards becomes a jointed Pod, containing one Cylindrical Seed in each Partition.*

The *Species* are;

1. ANIL, *ſive Indigo Americana, ſiliquis in falculæ modum contortis. D. Merchand. Mem. Ac. Reg. Scien. Anno* 1718. The true Indigo, with Pods, ſhap'd like a Sickle.
2. ANIL, *ſive Indigo Americana, fruticoſa, argentea, floribus e viridi purpureis, ſiliquis falcatis. Coluteæ affinis, fruticoſa argentea floribus ſpicatis e viridi purpureis, ſiliquis falcatis. Sloan. Cat. Jam.* The wild Indigo. *Vulgo.*
3. ANIL, *ſive Indigo, ſiliquis latis aliquantulum incurvis. Emerus, Indicus, ſiliqua aliquantulum incurva, ex quo Indigo. Breyn.* Indigo, with broad Pods a little crooked.

The firſt and third of theſe Species are Annuals with us; the Seeds of theſe muſt be ſown on a Hot-bed in the Spring of the Year; and when the Plants are come up two Inches high, they ſhould be tranſplanted into ſmall Pots filled with good freſh Earth, and the Pots plung'd into a Hot-bed of Tanners-bark; and when the Plants have obtain'd ſome Strength, they muſt have a great deal of free Air, by raiſing the Glaſſes in the Day-time, and in *June* they may be expos'd to the open Air, by which time they will produce their Flowers, which will be ſucceeded by Pods in a very ſhort Time after; and in *Auguſt* their Seeds will be perfected.

The ſecond Sort grows to the Height of five or ſix Feet, and will abide two or three Years, if it is preſerv'd in a very warm Stove in Winter: This produces Spikes of Flowers from the Wings of the Leaves on the Sides of the Stems of the Plant, and doth ſometimes perfect its Seeds in *England*. This muſt be raiſed in a Hot-bed, as was directed for the two former, but muſt not be expos'd to the open Air, even in the hotteſt Weather.

The firſt and third Sorts are ſuppos'd to be promiſcuouſly uſed to make the Indigo; but the firſt is the common Sort, which is cultivated in the *Engliſh* Plantations in *America*: But I have been aſſur'd by a Perſon of great Credit, that he has made as good Indigo from the ſecond Sort, as any that was produced in our Plantations; and this being a much larger Plant, will afford a greater Quantity from the ſame Compaſs of Ground, than any one of the other two Species; and this Sort is alſo much hardier, and may be cultivated in ſuch Places where the firſt Sort will not grow, by which Means great Improvements may be made with this Plant in our *American* Plantations.

The whole Proceſs in making the Indigo being exactly deſcrib'd by *Pere Labat*, in his Voyages, I thought it would not be unacceptable to the *Engliſh* Reader, to tranſlate his Account in this Place, which is as follows:

There was formerly a great deal of Indigo made in the Pariſh of *Macauba*; there is not a Stream nor River in it, where one does not meet with Indigo-works, that is, Backs or Vats of Stone-work, well cemented, in which the Plant that yields the Dye is put to digeſt: There are uſually three of theſe Vats one above another, in the Manner of a Caſcade, ſo that the ſecond, which is lower than the Bottom of the firſt, may receive the Liquor contain'd in the firſt, when the Holes, which are made in the Bottom of the firſt, are unſtopp'd; and that the third may in its Turn receive what was in the ſecond.

The firſt, largeſt, and higheſt of theſe Vats is called the Steeper or Rot; it is uſually made twenty Feet long, twelve or fifteen Feet wide, and three or four Feet deep: The ſecond is call'd the Battery; it is almoſt half as ſmall again as the firſt: And the third, which is much leſs than the ſecond, is call'd the Deviling.

The Names of the two firſt perfectly agree with their Uſes; for the Plant is laid to ſteep in the firſt, where it ferments, is macerated, and becomes like rotten Dung, after that the Salts and Subſtance of the Leaf and Rind are diffus'd in the Water by the Fermentation, which the Heat and Ripeneſs of the Plant has excited in it. It is in the ſecond that they agitate and beat this Water, impregnated and loaded with the Salts of the Plant, till having collected, reunited, and as it were, coagulated them with one another, they form the Particles which compoſe the Dye.

As for the Name of the third, I do not ſee how it agrees with it; unleſs it be becauſe this Vat is deeper colour'd than the others; for the Indigo already form'd remaining in it, conſequently dyes and colours it much deeper than the others.

To which I ſhould add, that 'tis only at St. *Domingo* that they make uſe of this Name. In the Windward Iſlands, they call this laſt Vat the Settler; and this Name ſuits it perfectly well; becauſe it is in this, that the Indigo begun in the Steeper, and perfected in the Battery, unites, grows into a Maſs, ſeparates itſelf from the Particles of Water which remain'd in it, leaves them at Top, and ſettles at the Bottom of the Vat, whence it is taken out to be put into little Bags, and then into the Boxes, as I ſhall mention hereafter.

Nothing ought to be omitted in the building and making theſe Vats ſubſtantial; the Strength of the Fermentation is ſo great, that unleſs the Stone-work and Plaiſter be very well done, and the Mortar carefully choſen and wrought, they crack; and a very moderate Crack is ſufficient to let out a Vat of Indigo, and cauſe a conſiderable Loſs to the Owner.

When this Misfortune happens, the following is an eaſy and infallible Remedy, which I can anſwer for, as having experienced it. Take ſome Sea-ſhells, of any Kind whatever, pound them without burning them, powder them, and ſift them thro' a fine Sieve. Take an equal Quantity of Quicklime, and ſift it, mix theſe together with Water enough to make a Stiff-mortar, and as quick as you can, ſtop the Cracks of your Vats with it. This Mixture incorporates, ſticks, and dries in a Moment, and immediately prevents the Matter's running out of the Vat.

Every-body does, or ſhould know, that Indigo is a Dye uſed to dye Wool, Silk, Cloaths and Stuffs blue; the *Spaniards* call it Anilo: The fineſt they make, *i. e.* in *New-Spain*, comes from *Guatimala*; which makes a great many People call it barely *Guatimalo*. It is made alſo in the *Eaſt-Indies*, particularly in the Dominions of the *Great Mogul*, the Kingdom of *Golconda*, and other Places thereabouts, as Mr. *Tavernier* relates in his Voyages. This Sort is in *Europe* oftener called India than Indigo or Anil, People taking for its proper Name, the Name of the Place it was made at.

Some Authors, and among others, Father *Du Tertre* of our Order, have fancied, that the Indigo which comes from the *Eaſt-Indies*, is more beautiful, finer and dearer, than that which comes from the *Weſt-Indies*, which they call flat Indigo, while they call that from the *Eaſt* barely India. They would have ſpoke more properly, if they had called the latter Round India; for, by their Leave, all the Difference between the two India's, or Indigo's, is, that that made in the *Eaſt-Indies*, is ſhap'd like half Eggs, and that of the *Weſt* like Cakes; for as for Goodneſs and Beauty, the one will not be a whit ſuperior to the other, if both are wrought with equal Care and Fidelity.

The Shape of the Oriental Indigo, obliges the Merchants, who would carry it into *Europe*, to pound it, that they may put the more into the Cheſts, or Barrels they put it up in. It is certain, that being thus pounded, its Grain having been broke under the Peſtle, ground, and reduc'd to Powder, makes it finer than the *Weſt-Indian* Indigo, which coming in Cakes, juſt as it was dried, ſhews its Grain intire, and conſequently muſt appear coarſer; but what is that to the intrinſick Goodneſs of the Commodity? I maintain, 'tis the ſame in both, tho' there ſeems to be a Difference.

To be convinc'd of this Truth, take a Lump of Sugar equally white throughout, break it in two, pound one Part of it, and reduce it to Powder; this will look finer and whiter than that which is whole; which proceeds only from this, that the Grain of the one has been ſeparated and divided into a greater Number of Parts, which, tho' very ſmall, and almoſt inſenſible, yet have a greater Number of Surfaces, and conſequently reflect more Light; whereas the other remaining intire, preſenting to the Sight only a large Grain, which has but little Surface, of courſe reflects leſs Light, and by a neceſſary Conſequence muſt appear leſs white; which is the ſame as appearing leſs beautiful, ſince the Beauty of Sugar conſiſts in its Whiteneſs. Methinks we may reaſon in the ſame Manner upon Indigo, and ſay, that, *cæteris paribus*, the *Weſt-Indian* Indigo is as beautiful as the *Eaſt-Indian*, when they are both wrought alike.

I think I ſhould add, that the *American* Indigo is better for Uſe than the other; for who does not ſee, that there is no pounding this Dye, without the moſt ſubtile Parts being diſſipated in the Air, as Mr. *Tavernier* allows; and who can doubt that theſe Parts are the beſt, and thoſe that go fartheſt, when it is us'd?

I grant, that the Indigo which comes from the *Eaſt-Indies*, is dearer than that which is made in the *Weſt-Indies*; the Reaſon is plain, it comes farther, runs greater Riſks; and thoſe who bring it, would not find their Account in ſelling it, at the ſame Price with that which comes from a much nearer Place; but that does not at all prove it to be more beautiful, or better.

Indigo is compos'd of the Salt and Subſtance of the Leaves and Rind of a Plant of the ſame Name; ſo that one may ſay, it is a Diſſolution, or Digeſtion of the Plant, caus'd by the Fermentation it has excited in the Water it was laid to ſteep in. I know ſome Writers pretend, that the Subſtance of the Leaves does not produce the Indigo, which (as they would have it) is only a viſcous Tincture, or Colour, which the Fermentation of the Plant diffuſes in the Water; but before I take their Words for it, I deſire they would tell me what becomes of the Subſtance of the Plant; for when it is taken out of the Steeper, it is certain, that it has no longer the ſame Weight, Conſiſtence, nor Colour it had before. The Leaves, which were very plump, and very full of Juice, are light, flabby and wither'd, and look more like Dung than any thing elſe; which makes them frequently give the Name of Rot to the Steeper. If then we no longer find in the Leaves, and the reſt of the Plant, the ſame Subſtance that was obſervable in it before it was laid to ſteep, is it not moſt natural to believe, that 'tis the ſame Subſtance and Salts, which, being freed from their Incloſures, and diffus'd in the Water, have thicken'd it, and by their Union or Coagulation have form'd that blue Maſs, which they call Indigo, ſo uſeful in Painting and Dying?

The Culture.] This Plant requires a good rich level Soil, not too dry; it greatly robs and impoveriſhes the Ground where it grows, and muſt be alone. There cannot be too much Care taken to keep it clean, and to hinder the Herbs of any Kind whatever from growing near it. They weed and cleanſe the Ground where they intend to plant the Indigo Seed, five times over. I ſhould think they ſhould call it ſowing; but the Term of Planting is conſecrated in our Iſles, and I do not think I ought for the Sake of a Word to fall out with our Planters, who deſerve our Eſteem upon a thouſand Accounts, though they have got a Habit of murdering the *French* Language. They ſometimes carry their Neatneſs to ſuch a Pitch, that they ſweep the Piece of Ground, as they do a Room. After that, they make the Holes or Pits, wherein the Seeds are to be put; for this Purpoſe, the Slaves, or others, who are to work at it, range themſelves in the ſame Line, at the Top of the Piece of Ground, and going backwards, they make little Pits of the Breadth of their Hough, of the Depth of three or four Inches, at about a Foot Diſtance every way, and as much as poſſible in a ſtrait Line. When they are come to the End of the Ground, each furniſhes himſelf with a little Bag of Seeds, and returning that way they came, they put eleven or thirteen Seeds into each of the Holes they have made. A Relick of Superſtition has taught them, that the Number muſt be odd. I by no means approve of this Practice, but I ſhall take care not to endeavour to ſhew them the Uſeleſneſs and Folly of it, being ſatisfy'd I ſhould only loſe my Time and Labour.

This Work is the moſt Toilſome of any in the Manufacture of Indigo; for thoſe who plant it, muſt be always ſtooping, without riſing up, till the planting of the whole Length of the Piece is ended; ſo that when that is large, which almoſt always happens, they are obliged to remain two Hours, and often more, in this Poſture.

When they come to the Top of the Piece, they go back again, and cover the Holes they have put the Seed in, by thruſting in with their Feet, the Earth they had taken out of them, and ſo the Seed is cover'd with about two Inches of Earth.

Tho' all Seaſons are good for the planting of Indigo, yet Care muſt be taken not to put it in the Ground in a dry Time; 'tis true, the Seed may keep a whole Month in the Ground, without being ſpoiled; but when it is planted ſo, one runs the Riſk of having it eaten up by Vermin, or carried away by the Wind, or choak'd by the Weeds, that ſpring up with it; ſo that the prudent Planters never run the Riſk of planting it dry, *i. e.* at a Time when they do not probably expect Rain in two or three Days after the planting is ended: They chuſe therefore, uſually, a moiſt Seaſon, which promiſes Rain, and then they are ſure of ſeeing the Plant ſpring up in three or four Days after its being planted.

Notwithſtanding all the Care that has been taken in clearing the Ground, where the Seeds have been planted, the Planter muſt not be careleſs, when the Indigo is got above Ground; becauſe the Goodneſs of the Soil, join'd to the Moiſture and Warmth of the Climate, and the plentiful Dews that fall every Night, makes a prodigious Quantity of Weeds ſpring up, which would choak, and abſolutely ſpoil the Indigo, if extreme Care was not taken to weed them up as ſoon as they appear, and to keep the Plant extraordinary neat; and very often the Weeds are partly the Cauſe of the Breeding of a Kind of Caterpillars, which devour all the Leaves in a trice.

From the Time of the Plant's riſing above Ground, to its perfect Maturity, is but two Months, and then it is fit to cut; if one was to ſtay longer, it would bloſſom, its Leaves would grow drier and harder, and conſequently they would yield leſs Subſtance, and the Colour would not be near ſo beautiful.

After this firſt Cutting, the new Branches and Leaves, which the Plant produces, may be cut about every ſix Weeks, provided the Seaſon be rainy, and that Care be taken, not to cut it in a Time of Drought, becauſe then we ſhould infallibly loſe the Plant, or, as they call it there, the Choupues, and be obliged to plant again; but all Things being rightly managed, the Plant may laſt two Years, after which it muſt be plucked up, and new ones planted.

When the Plant is ripe, which is known by the Leaves, which grow brittler and leſs ſupple, they cut it ſome Inches from the Ground. They uſe for the Cutting of it, great crooked knives made like Sickles. Some Planters make it into Bundles like double Bottles of Hay, that a Negro may eaſily carry them to the Steeper; but moſt People put it into large Pieces of coarſe Cloth, which they tie by the four Corners; and this is more convenient, the Plant is leſs handled and ſqueezed, and the ſmall are carried away as ſafely as the great; and beſides, the Work goes on quicker this way, than in making Bottles; and as Time is precious every where, and eſpecially in *America*, there can't be too much Care taken not to loſe any.

Eighteen or twenty Packets of Plants, each about the Size of two Bottles of Hay, are ſufficient to fill a Steeper of the aforementioned Size. When it is fill'd with Water, ſo that it covers the Plants, they put Pieces of Wood on the Top, that the Plants may not riſe above the Water, (much as they do upon the Grapes that are put into the Preſs) and let all ferment. According as the Heat is greater or leſs, or the Plant more or leſs ripe, the Fermentation is raiſed ſooner or later, ſometimes in ſix, eight, or ten Hours, and ſometimes one is obliged to wait eighteen or twenty Hours,but very ſeldom longer. Then the Effect of the Fermentation viſibly appears, the Water heats and boils up on all Sides, as the Grapes do in the Vat, and the Water, which at firſt was clear, inſenſibly grows thick, and becomes of a blue, inclining to a violet Colour. Then, without meddling at all with the Plants, they open the Cocks, which are at the Bottom of the Steeper, and let all this Water, loaded with the Salts and Subſtance of the Plant, which were freed by the Fermentation, run into the Battery; and while they throw away, as uſeleſs and almoſt rotten, the Plants that were in the Steeper, and clean it, that it may be filled with freſh, they beat the Water, which they have let out of the Steeper, into the Battery.

They formerly uſed for this Purpoſe, a battle-door Wheel, whoſe Axle was placed upon the middle of the Vat, and which they turn'd by two Handles, that were at the End of the ſame Axle. Since that in the room of Battle-doors, they have put little bottomleſs Boxes, and afterwards others, whoſe Bottoms were bored full of Holes: At preſent they uſe a Kind of pretty large Pails, faſten'd to ſtrong Poles, plac'd upon Chandeliers, by Means of which, the Negroes violently and continually raiſe, beat, and ſtir the Water, till the Salts and other Parts of the Subſtance of the Plant are united, and ſufficiently, as it were, coagulated to incorporate.

The hitting this Minute exactly ſhews the Skill of him, who overſees the making of the Indigo: For if he makes them leave off beating a little too ſoon, the Grain, not yet form'd, remains diſpers'd in the Water, without ſinking and gathering together at the Bottom of the Vat, and is loſt with the Water, when they are obliged to let it out; which is a great Loſs to the Owner: Or if, when it is form'd, they continue to beat, they diſſolve it, and the ſame Inconvenience follows. This Minute then muſt be nick'd, and when it is found, they muſt leave off beating, and let the Matter reſt.

To find this Minute, they make uſe of a little ſilver Cup, deſign'd for this Uſe alone: They fill it with this Water, while the Negroes beat it, and according as they obſerve that the *Fæces* ſink to the Bottom of the Cup, or remain diſpers'd in the Water, they ceaſe, or continue beating.

The General Dictionary printed at *Trevoux* relates very ſeriouſly, upon the Credit of Father *Plumier* a *Minim*, that the Indigo-maker, having taken up ſome of the Water of this Battery in his Cup, ſpits in it, and that if the Indigo be form'd, the *Fæces* immediately ſink to the Bottom of the Cup, and that then he makes them leave off beating, if not, he makes them continue it. This is not the only Incident in which People have impos'd upon Father *Plumier*'s Credulity and Simplicity. I have been a Witneſs of it upon other Occaſions and perhaps ſhall relate ſome of them in the Sequel of theſe Memoirs.

This is what Men expoſe themſelves to, who will pretend to give an Account of a Country, which they ſee only *en paſſant*, and, as it were, in running thro' it. They often apply to People who know very little of what they want to be inform'd of, and who had rather tell them a fooliſh Story than ſeem ignorant; and ſtill oftener they fall into the Hands of ſome profeſs'd Banterers, which the Iſlands are pretty well ſtor'd with, who take a Pleaſure in impoſing upon them, that they may afterwards ridicule them, when an Opportunity offers. I ſcarce ever knew a Man more eaſily deceiv'd than this honeſt Frier. He had a wonderful Talent at deſigning Plants, and he was capable of producing finiſh'd Pieces in that way, if he had ſtuck to that alone; but he has fallen into a vaſt Number of Blunders, by having endeavour'd to go out of his own Sphere, of which that I have juſt taken Notice of is not one of the moſt conſiderable.

When they have left off beating, they let the Matter reſt, the *Fæces* ſink to the Bottom of the Vat, and gather together like a kind of Mud, and the Water, freed from all the Salts it was impregnated with, ſwims above it, and grows clear. Then they open the Cocks, which are plac'd in the Battery at different Diſtances from the Bottom, and let this Water run away, and when they come to the Surface of the *Fæces*, they open the Cocks of the Bottom, that the *Fæces* may all fall into the Deviling or Settler. There they let it ſettle a little while longer, after which they put it into little linnen Bags, fifteen or eighteen Inches long, made with a Point, where it perfectly purges itſelf from the reſt of the Water, which remain'd among its Particles. When that is done, they ſpread it in little Boxes, three or four Feet long, two Feet broad, and about three Inches deep, and expoſe it to the Air to dry it perfectly. They obſerve not to expoſe it to the Sun, becauſe it would ſtarve the Colour in drying it, and they take a great deal of Care to keep from the Rain, becauſe that would diſſolve and utterly ſpoil it.

It ſometimes happens, that the Caterpillars get among the Indigo, and, if they are let alone ever ſo little a while, they eat all the Leaves, and often the very Rind and Ends of the Branches, and kill the Stocks; 'tis but loſt time to endeavour to deſtroy them, or hinder them from ravaging a whole Piece, by ſtopping them with a Ditch. The ſureſt Way is to cut down the Indigo with all Speed, let its Age be what it will, and to throw both Plants and Caterpillars pell-mell together into the Steeper; they there burſt, and part with what they had devour'd, and the Indigo is not the leſs beautiful for it. 'Tis true, when the Plant is not come to its perfect Maturity, it yields much leſs; but many Experiments have taught us, that the Colour it yields is much more beautiful; ſo that what is loſt one Way, is gain'd another.

I would not wait for ſo perfect a Ripeneſs, before I cut the Plant. Perhaps all the Secret of thoſe, whoſe Indigo is ſo much extoll'd beyond ours, lies only in cutting the Plant, when it yields the livelieſt Colour. I have experienced, that in leaving ſome Cochineal-flies upon ſome *Indian* Figs, which were too ripe, inſtead of being red, they grew of a fillemot Colour, like the Fruit they fed upon. The ſame thing might happen in Indigo, and what I here propoſe, is not a groundleſs Doubt, ſince it is back'd by the certain Experiment I have juſt related, which plainly proves, that the ſame Plant cut at different Ages, produces Colours different in Beauty. I would not venture to give this Advice to Men wedded to their Intereſt, who valued the Quantity rather than the Quality of their Commodity; but I believe I have nothing to fear from our Iſlanders, who are generous and magnificent, ſometimes even beyond their Abilities: I adviſe them therefore to make different Trials, as to the Soil, the Seaſon, the Age of the Plant, the Water they ſteep it in, the Point of Diſſolution, *&c.* And I am ſure, that with a little Time, Labour, and Patience, they will make Indigo, that will equal and even excel the moſt boaſted Indigo of foreign Countries. The Planters of St. *Domingo*, know, that in 1701, their coarſe Sugar was very bad, and was not made without infinite Trouble; and at preſent every-body allows, that by their Labour, Aſſiduity, and Enquiries, it is grown much more eſteem'd than that of the Windward Iſlands: Why may not the ſame be hop'd for in Indigo?

Mr. *Pomet*, Author of the Gen. Hiſt. of Drugs, ſays in his firſt Part, Chap. 10. that the *Indians* of the Village of *Sarqueſſe*, near *Amadabat*, uſe only the Leaves of the Indigo, and throw away the Plant and Branches; and that 'tis from thence the moſt eſteem'd Indigo comes.

I am pretty much of his Opinion; for we ſee, that thoſe who take the Pains to ſtrip off the Grapes from the Strigs, before they put them into the Vat, and throw away the Strigs intirely, make much the beſt Wine, becauſe the Strigs always contain an Acid, which mixes with the Juice of the Grape in the treading and preſſing them both together; and for the ſame Reaſon, the Indigo-plant muſt contain a Liquid much leſs perfect in Colour than that of the Leaves: But one ought to have the Leiſure and Patience of the *Indians*, to undertake ſuch a Work, and have Workmen as cheap as they are in that Country, ſuppoſing the Fact true, as Mr. *Pomet* delivers it from the Relation of Mr. *Tavernier*.

Tho' I am a great Friend to thoſe Experiments, which may carry our Manufactures to a greater Perfection, yet I dare not propoſe this, becauſe of the Expence they muſt be at, who would try it, and becauſe the Profit ariſing from it would not perhaps quit Coſt: However, I have here given the Method of the *Indians* of *Sarqueſſe*, that I may have no Reaſon to reproach myſelf with having omitted a Thing, which may be of ſome Uſe to my Country.

Good Indigo ought to be ſo light as to ſwim upon Water; the more it ſinks, the more it is to be ſuſpected of being mix'd with Earth, Aſhes, or powder'd Slate. Its Colour ought to be a deep Blue, inclining to a Violet, brilliant, lively, and bright; it ought to be more beautiful within than without, and look ſhining, and as it were ſilver'd.

If 'tis too heavy in proportion to its Bulk, it ought to be ſuſpected, and its Quality examin'd into; for as it often bears a conſiderable Price, it is fit that thoſe who buy it, ſhould be acquainted with the Frauds that may be committed in it.

The firſt is the beating the Plant too much in the Steeper, that the Leaves and Rind of it may be intirely conſum'd. 'Tis certain, that the Quantity of the Matter is very conſiderably increas'd by this Diſſolution, but the Indigo is a great deal the leſs beautiful for it; it is blackiſh, thick, heavy, and fitter to be thrown away than us'd.

The ſecond is the mixing Aſhes, Earth, or a certain brown ſhining Sand (which is pretty commonly found in the Bays by the Sea-ſide) and eſpecially powder'd Slate, with the *Fæces*, as they fall into the Deviling, and ſtirring all well together, that it may incorporate, and the Fraud not appear: And this Fraud is much more eaſily committed in the powder'd Indigo, than in that which is in Cakes, becauſe it is very difficult for thoſe heterogeneous Bodies to unite ſo well together, as not to make in many Places, as it were, Beds of a different Matter; and then by breaking the Piece of Indigo, they are eaſily perceiv'd.

The two following Expedients may be made uſe of, in order to know the Goodneſs or Badneſs of Indigo.

The firſt is to diſſolve a Bit of it in a Glaſs of Water. If it is pure and well made, it will intirely diſſolve; but if it is adulterated, the foreign Matter will ſink to the Bottom of the Glaſs.

The ſecond is to burn it. The good Indigo will burn all away, whereas the Aſhes, Earth, Sand, and Slate, remain after the true Indigo is conſum'd.

In 1694, Indigo was ſold at the Windward Iſlands, from three Livres ten Sols, to four Livres *per* Pound, according to its Beauty, and the Number of Veſſels to be freighted with it. I have known it ſince at a much lower Price; however, the Planter would not fail of making a very conſiderable Profit of it, tho' he ſhould ſell it for no more than forty Sols *per* Pound, becauſe this Commodity requires fewer Utenſils and leſs Charges than a Sugar-Work.

ANISUM *or* ANISE. *Vide* Apium.

ANONA.

The *Characters* are;

It is a Tree growing to the Height of an Apple-tree; the Leaves are, for the moſt part, ſingle and oblong; the Flowers do, for the moſt part, conſiſt of three thick, narrow Petals, or Flower-leaves, and are produced ſingle upon their Foot-ſtalks; theſe Flowers are ſucceeded by conical, ſquamous, or netted Fruit, which have a pulpy Subſtance ſurrounding the Cells, in which are contained oblong hard Seeds.

The *Species* are;

1. ANONA *maxima, foliis latis ſplendentibus, fructu maximo, viridi, conoide, tuberculis ſeu ſpinulis innocentibus aſpero. Sloan. Cat. Pl. Jam.* The Sour-ſop: *Vulgo.*
2. ANONA *maxima, foliis oblongis anguſtis, fructu maximo luteo, conoide, cortice glabro, in areolas diſtincto. Sloan. Cat. Pl. Jam.* The Cuſtard-apple: *Vulgo.*
3. ANONA *foliis odoratis minoribus, fructu conoide ſquamoſo parvo dulci. Sloan. Cat. Pl. Jam.* The Sweet-ſop: *Vulgo.*
4. ANONA *aquatica, foliis laurinis atro-virentibus, fructu minore conoide luteo, cortice glabro in areolas diſtincto. Sloan. Cat. Pl. Jam.* The Water *or* Sweet-apple: *Vulgo.*
5. ANONA *foliis ſubtus ferrugineis, fructu rotundo majore lævi purpureo, ſemine nigro, partim rugoſo, partim glabro. Sloan. Cat. Pl. Jam.* The Star-apple: *Vulgo.*
6. ANONA *foliis laurinis, glabris, viridi-fuſcis, fructu minore rotundo viridi-flavo, ſcabro, ſeminibus fuſcis, ſplendentibus, fiſſura alba notatis. Sloan. Cat. Pl. Jam.* The Sappadilla *or* Naſeberry-tree: *Vulgo.*
7. ANONA *maxima, foliis laurinis, glabris, viridi-fuſcis, fructu minimo, rotundo, viridi-flavo, ſeminibus fuſcis, ſplendentibus, fiſſura alba notatis. Sloan. Cat. Pl. Jam.* The Bully-tree: *Vulgo.*

Theſe Trees are the Produce of the warmeſt Parts of the *Weſt Indies*, as in *Jamaica*, *Barbadoes*, &c. where they are cultivated for their Fruits, which are in thoſe Countries in very great Eſteem, eſpecially the *Sappadilla*, which they value more than any of the other Sorts, and hath been but lately introduced into ſome of thoſe Iſlands. It is very probable that none of theſe Trees were originally Natives of theſe Countries, but have been tranſplanted from ſome other Parts of the World; but being there planted, they thrive equally as well as if it were their native Soil, the *Sappadilla* only excepted, which is of a tenderer Nature than the others.

The Seeds of theſe Trees are frequently brought over from the *Weſt Indies* to *England*; but there are, at preſent, but few of the Plants in Being amongſt us, they being of ſo nice a Nature as not to endure our open Air in Summer; nor will they live thro' the Winter, unleſs preſerved in the warmeſt Stoves.

Theſe Seeds ſhould be ſown in ſmall Pots, filled with rich light Earth, early in the Spring, and the Pots muſt be plunged into a warm Bed of Tanners Bark, obſerving frequently to refreſh the Earth in the Pots with Water, but give them little each Time, leſt by too much Moiſture the Earth ſhould be chill'd, and the Seeds be thereby ſtarved. If the Seeds were freſh, and the Bed in a kindly Temper for Heat, the Plants will come up in about three Weeks or a Month's time, and will make a conſiderable Progreſs in a ſhort time after; therefore they ſhould be tranſplanted, each Plant into a ſingle Pot, being careful in doing it not to ſhake the Earth clean from the Roots; then plunge the Pots into the ſame Hot-bed, (provided the Bark hath not loſt its Heat, which if it has, it ſhould be ſtirred up with a Dung-fork, mixing therewith ſome freſh Tan) and give the Plants a little Water to ſettle the Earth to their Roots, obſerving to ſhade them from the Sun, during the Heat of the Day, until they have taken freſh Root; after which you muſt conſtantly refreſh them with Water, as you will ſee Occaſion, and give them Air, by tilting up the Glaſſes in Proportion to the Heat of the Weather, and the Bed in which they are plunged.

In about two Months after this, the Plants will have made a conſiderable Advance, and the Pots will be filled with their Roots; you muſt therefore remove them into Pots of a little larger Size; in doing of which you ſhould take the Plant out of the ſmall Pot, with all the Earth about its Root, then with a Knife gently trim off all the Roots which are on the Outſide of the Ball of Earth, and after having put ſome freſh Earth into the Bottom of the new Pot, place the Plant exactly in the Middle, filling the Vacancies round the Root with the ſame freſh Earth; then plunge theſe Pots again into the Hot-bed, giving them Water and Air as you ſhall judge neceſſary; but obſerve in *Auguſt* to give them a great deal of freſh Air, whenever the Weather will permit, that they may be harden'd to go thro' the Approaching Winter.

Towards the latter End of *September* you ſhould be provided with a freſh Bark-bed in a Stove, (erected on purpoſe for theſe and other the like tender Plants) into which you muſt remove the Pots, when the Bark has lain about ten Days to ſettle and heat; but if upon opening the Bark, to plunge in the Pots, you find the Heat very great, you ſhould ſet the Pots but half way into the Bark at firſt, until the Heat is a little more abated, when you may ſink them down to the Rims: During the Winter Seaſon you muſt be very moderate in watering them, and alſo obſerve to keep the Stove in a due Temper of Heat: The Warmth in which they have beſt ſucceeded in Winter, is about ten Degrees above the Temperate Point, as mark'd on Mr. *Fowler*'s Thermometers.

In the Spring, *viz.* about the Middle of *March*, you ſhould be provided with a freſh Parcel of Tan, which ſhould be laid up in a Heap, in ſome dry Place, about ten Days before it is uſed: This Tan ſhould be mixed with the old Tan, already in the Stove, which ſhould be ſtirred up, and well mixed with the new. This will add a freſh Heat to the Bed, whereby the Plants will be put into Motion, and begin to grow; which muſt be ſhifted into bigger Pots as they advance, and in the Summer ſhould have a good Quantity of Air, when the Weather is warm. With this Management I have ſeveral of theſe Plants in good Health, which are ſeven or eight Feet high; ſome of which have produced Flowers with me; but I have not had any Fruit form'd as yet.

ANONIS, Cammock Petty Whin, or Reſt-harrow; [Ἄνωνις, or ὀνωνὶς, of ὄνος, an Aſs, becauſe Aſſes are ſaid to rub themſelves againſt this Plant.]

The *Characters* are;

It hath a papilionaceous Flower, which is ſucceeded by a ſwelling Pod, which is ſometimes long, and at other times ſhort, is bivalve, and filled with Kidney-ſhaped Seeds.

The *Species* are,

1. Anonis *ſpinoſa, flore purpureo. C. B.* Anonis or prickly Reſt-harrow, with purple Flowers.
2. Anonis *ſpinoſa, flore albo. C. B.* Prickly Reſt-harrow, with white Flowers.
3. Anonis *ſpinis carens, purpurea. C. B.* Purple Reſt-harrow, without Prickles.
4. Anonis *ſpinis carens, candidis floribus. C. B.* Reſt-harrow without Prickles, and white Flowers.
5. Anonis *ſpicata, ſive alopecuroides, Luſitanica. Hoſm. Cat.* *Portugal* Reſt-harrow, with Spikes of purple Flowers.
6. Anonis *purpurea, verna, ſeu præcox, perennis, fruteſcens, flore rubro amplo. Mor. Hiſt.* Early ſhrubby purple Reſt-harrow, with ample red Flowers.
7. Anonis *lutea, anguſtifolia, perennis. Boerh. Ind.* Yellow narrow-leav'd perennial Reſt-harrow.
8. Anonis *ſiliquis ornithopodii. Boerh. Ind.* Reſt-harrow, with Pods like the Bird's-foot.
9. Anonis *Americana, folio latiori ſubrotundo. Tourn.* *American* Anonis, with broad roundiſh Leaves.
10. Anonis *Caroliniana perennis non ſpinoſa, foliorum marginibus integris, floribus in thyrſo candidis.* Smooth perennial *Carolina* Reſt-Harrow, with intire Leaves, and white Flowers growing, in a looſe Spike.
11. Anonis *Hiſpanica fruteſcens, folio tridentato carnoſo. Inſt. R. H.* Shrubby *Spaniſh* Reſt-Harrow, with a tridented fleſhy Leaf.
12. Anonis *Alpina humilior, radice ampla et dulci. Inſt. R. H.* Dwarf Reſt-Harrow of the *Alps*, with a large ſweet Root.
13. Anonis *Alpina pumila glabra non ſpinoſa purpurea. Inſt. R. H.* Dwarf ſmooth purple Reſt-Harrow of the *Alps*.
14. Anonis *Hiſpanica fruteſcens, folio rotundiori. Inſt. R. H.* Shrubby *Spaniſh* Reſt-Harrow, with a rounder Leaf.
15. Anonis *fruteſcens Americana, flore purpurea. Inſt. R. H.* Shrubby *American* Reſt-Harrow, with a purple Flower.
16. Anonis *Aſiatica fruteſcens, floribus luteis amplis. Inſt. R. H.* *Aſiatic* ſhrubby Reſt-Harrow, with large yellow Flowers.
17. Anonis *Americana anguſtifolia humilior, & minus hirſuta. Houſt.* Dwarf narrow-leav'd *American* Reſt-Harrow.
18. Anonis *non ſpinoſa, foliis ciſti inſtar, glutinoſis & odoratis. Sloan. Cat. Jam.* Shrubby glutinous and ſweet-ſmelling *American* Reſt-Harrow, without Thorns, and Leaves like the Dwarf *Ciſtus*.
19. Anonis *Americana erectior non ſpinoſa, foliis rotundioribus, floribus amplis luteis.* Upright *American* Reſt-Harrow, without Spines, having round Leaves, and large yellow Flowers.
20. Anonis *viſcoſa, ſpinis carens, lutea major. C. B. P.* Large yellow Reſt-Harrow, without Spines.
21. Anonis *ſpinis carens, lutra minor. C. B. P.* Smaller yellow Reſt-Harrow, without Spines.
22. Anonis *flore luteo parvo. H. R. Par.* Reſt-Harrow, with a ſmall yellow Flower.
23. Anonis *puſilla glabra anguſtifolia lutea. Inſt. R. H.* Smooth narrow-leav'd Dwarf Reſt-Harrow, with a yellow Flower.
24. Anonis *non ſpinoſa, flore luteo variegato. C. B. P.* Smooth Reſt-Harrow, with a yellow variegated Flower.
25. Anonis *non ſpinoſa hirſuta viſcoſa, odore theriacæ. Hort. Cath. Sup.* Hairy viſcous Reſt-Harrow, without Spines, and ſmelling like Venice-treacle.
26. Anonis *non ſpinoſa minor glabra procumbens, flore luteo. Sloan. Cat.* 75. Leſſer trailing ſmooth *American* Reſt-Harrow, without Spines, and having yellow Flowers.

The four firſt Sorts grow wild in divers Parts of *England*, and are ſeldom propagated in Gardens: the firſt Sort is uſed in Medicine; the Roots of this Plant ſpread very far under the Surface of the Ground, and are ſo tough, that in ploughing the Land it often ſtops the Oxen; from whence it had its Name, *viz. Reſta Bovis.* The ſecond Sort is but a Variety of the firſt, differing only in the Colour of the Flower. The two others, without Spines, are often met with near the firſt.

The fifth, ſixth, and ſeventh Sorts are beautiful Garden Plants; theſe are propagated by ſowing their Seeds in the Spring of the Year, in an open ſituated Bed of light Earth; and when the Plants are come up, they ſhould be tranſplanted carefully, either into Pots (filled with good freſh Earth) or into warm-ſituated Borders, for they are ſubject to be deſtroyed by hard Froſts; therefore it is that I would adviſe the preſerving ſome Plants of each Kind in Pots, which may be ſheltered in the Winter under a common Hot-bed Frame, and the Spring following may be turned out of the Pots (preſerving all the Earth to their Roots) and planted in a warm Border, where they may remain to flower; and if the Seaſon is good, they will perfect their Seeds in *Auguſt*, or ſooner.

The eighth and ninth Sorts are Annuals, and muſt therefore be ſown every Spring: The eighth will do very well, if ſown on a Bed of freſh Earth in the open Air, where it may remain to flower and ſeed; but the ninth ſhould be ſown on a moderate Hot-bed, and managed as is directed for the *Balſamina*; this will produce its Flowers in *July*, and the Seeds will ripen in *September*.

The tenth Sort is a perennial Plant, which dies to the Root every Winter, but riſes again the ſucceeding Spring. This Plant produces long Spikes of white Flowers in *June*, and the Seeds ripen in *September*. It is propagated from Seeds, which ſhould be ſown in the Spring upon a gentle Hot-bed; and when the Plants are come up, they ſhould be tranſplanted each into a ſeparate Half-penny Pot, filled with freſh Earth, and plunged on another very moderate Hot-bed, obſerving to water and ſhade 'em until they have taken Root, after which time they ſhould be inured to the open Air; and in the latter End of *June* the Pots ſhould be placed Abroad, where they may remain until the Middle of *October*, when they muſt be placed under a Hot-bed Frame, to ſhelter them in ſevere Froſt, but in mild Weather they ſhould have as much free Air as poſſible. The Spring following theſe Plants ſhould be taken out of the Pots, and planted in warm Borders, where they are to remain; for they ſhoot their Roots a great Depth into the Earth, ſo do not bear tranſplanting well after they have made ſtrong Roots. Theſe Plants will continue ſeveral Years, and as their Roots increaſe, ſo they will produce a greater Number of Flowers.

The eleventh, twelfth, thirteenth and fourteenth Sorts, are abiding Plants, which may be propagated by ſowing of their Seeds in the ſame manner as hath been directed for the tenth, and the young Plants ſhould alſo be treated the firſt Year as was directed for that Sort. The following Spring you muſt plant out the twelfth and thirteenth Sorts, into the full Ground, where they will thrive much better than if kept in Pots, and being both very hardy, they will endure the ſevereſt Cold of our Climate without Shelter. Theſe produce their Flowers in *April* and *May*, and in good Seaſons will ſometimes perfect their Seeds in *England*.

The eleventh and fourteenth Sorts become ſhrubby; theſe are more tender than the former Sorts, ſo that ſome of theſe Plants ſhould be kept in Pots, that they may be ſheltered from the Froſt in Winter, and the others may be planted in a warm Border, where they will endure the Cold of our ordinary Winters very well; but in very ſharp Winters, theſe Plants which are expoſed, will be deſtroyed. Theſe two Sorts flower in the Spring, (at which time they make a handſome Appearance amongſt other hardy Exotick Plants) and ſometimes they will produce ripe Seeds in *England*. They may alſo be propagated by Cuttings, which ſhould be planted in Pots filled with light rich Earth, and plunged into a very moderate Hot-bed, obſerving to water and ſhade them, until they have taken Root; after which time they ſhould be removed into the open Air, and ſhould remain Abroad until the End of *October*, or the Beginning of *November*, when they ſhould either be removed under a Hot-bed Frame, where they may be covered in froſty Weather, or elſe placed in the Greenhouſe, near the Windows; for they ſhould have as much Air as poſſible in mild Weather, otherwiſe they will produce weak Shoots, and ſeldom flower near ſo well as thoſe which are treated hardily.

The fifteenth, ſixteenth, ſeventeenth and eighteenth Sorts, are Natives of *America*. Theſe are alſo abiding Plants, which may be propagated by ſowing of their Seeds in ſmall Pots, filled with light freſh Earth, in the Spring of the Year; theſe Pots ſhould be plunged into a moderate Hot-bed of Tanners-bark, obſerving to water the Earth gently when you perceive it dry; but you muſt not give them too much Water, leſt it burſt the Seeds, and cauſe them to rot. In about three Weeks or a Month after ſowing, the Plants will appear, when they ſhould be frequently refreſhed with Water, to promote their Growth; and when they are two Inches high, they ſhould be ſhaken out of the Pots, and carefully parted, planting each Plant into a ſeparate ſmall Pot, filled with the ſame rich Earth as the Seeds were ſown in. Then the Pots ſhould be plunged again into a moderate Hot-bed of Tanners-bark, obſerving to water and ſhade them until they have taken Root; after which time they ſhould be conſtantly refreſhed with Water, as the Seaſon may require, and in warm Weather the Glaſſes of the Hot-bed ſhould be raiſed with Stones, to admit Air to the Plants in proportion to the Heat of the Weather. When the Plants have grown ſo as to fill theſe ſmall Pots with their Roots, they ſhould be ſhaken out of them, and tranſplanted into Pots a ſize larger, and then plunged into the Hot-bed again; for theſe Plants being Natives of warm Countries, they muſt be treated after the manner of other tender Exotick Plants. In Winter theſe Plants muſt be placed in the Bark-ſtove, but in Summer they ſhould have a large Share of freſh Air, otherwiſe they will not flower very ſtrong, nor will they ever produce good Seeds, if they have not Air and Moiſture in warm Weather.

The nineteenth and twenty-ſixth Sorts are alſo very tender Plants. Theſe are propagated by Seeds, which ſhould be treated exactly in the ſame manner as the former Sorts; but theſe are not laſting Plants, for they ſeldom continue longer than two Years; the ſecond Year they produce Flowers, and perfect their Seeds, after which they generally decay.

The twentieth, twenty-firſt, twenty-ſecond, twenty-third, twenty-fourth and twenty-fifth Sorts, are all annual Plants, which are hardy. The Seeds of theſe ſhould be ſown about the Middle of *March*, on a warm Border, where they are deſigned to remain; for they do not bear tranſplanting very well; ſo the beſt Method is, to ſow the Seeds in Drills, about two Feet aſunder, and when the Plants are come up, they ſhould be thinned ſo as to leave the Plants about five or ſix Inches apart in the Rows. This is all the Culture which theſe Plants require, unleſs it be to keep them clear from Weeds; which ſhould be conſtantly obſerved. In *July* theſe Plants will produce their Flowers, and in *September* they will perfect their Seeds, which ſhould be carefully gathered to preſerve their Species.

ANTHERÆ, [of Ἄνθος, a Flower, and ῥόδȣ, of a Roſe, *Gr.*] are the Summits or little Tops in the Middle of the Flower, ſupported by the *Stamina*. The *Chives*.

ANTHOLOGY, [of Ἄνθος and λόγος, *Gr.* a Word] a Diſcourſe or Treatiſe of Flowers.

ANTIRRHINUM, [Ἀντίῤῥινον, of ἀντὶ, againſt, and ῥὶν, the Noſtrils, as tho' it repreſented a Noſe: It is alſo call'd *Cynocephalus*, of κυνὸς, a Dog, and κεφαλὴ, a Head, becauſe its Fruit reſembles the Head of a Dog] Snap-dragon *or* Calves-ſnout.

The *Characters* are;

It is a Plant with an anomalous Flower, conſiſting of one Leaf, which is divided, as it were, into two Lips; the upper of which is cut into two Parts, and the under into three Parts: Out of the Flower-cup ariſes the Pointal, faſten'd like a Nail in the hinder Part of the Flower, which afterwards turns to a Fruit reſembling a Calf's-head, which is divided in the Middle by a Partition into two Cells, in which are contained many ſmall Seeds.

There are ſeveral Varieties of this Plant, which are worthy of a Place in large Gardens, for the Oddneſs of their Flowers, which continue blowing moſt Part of the Summer, and are very uſeful to compoſe Flower-pots to adorn Chimnies or Halls. The Sorts are;

1. ANTIRRHINUM *latifolium, flore rubro, rictu luteo. Boerh.* The Broad-leav'd Snap-dragon, with red Flowers.
2. ANTIRRHINUM *latifolium, flore albo, rictu luteo. Boerh.* The broad-leav'd Snap-dragon, with white Flowers.
3. ANTIRRHINUM *anguſtifolium majus, peregrinum, flore ruberrimo. H. R. Par.* The large narrow-leav'd Snap-dragon, with deep red Flowers.
4. ANTIRRINUM *anguſto folio linariæ, eleganter variegato, flore rubro, rictu luteo. Boerh.* The ſtriped Snap-dragon.
5. ANTIRRHINUM *luteo flore. C. B. P.* Snap-Dragon, with a yellow Flower.
6. ANTIRRHINUM *latifolium, pallido amplo flore. Bocc. Muſ.* Broad-leav'd Snap-Dragon, with a large pale Flower.
7. ANTIRRHINUM *Luſitanicum, flore rubro elegantiſſimo. Par. Bat.* *Portugal* Snap-Dragon, with a moſt elegant red Flower.
8. ANTIRRHINUM *Hiſpanicum villoſum, origani folio. Inſt. R. H.* *Spaniſh* hairy Snap-Dragon, with a wild Marjoram Leaf.
9. ANTIRRHINUM *Hiſpanicum altiſſimum, anguſtiſſimo folio. Inſt. R. H.* Tall *Spaniſh* Snap-Dragon, with a very narrow Leaf.
10. ANTIRRHINUM *medium, flore albo patulo. Virid. Luſit.* Middle Snap-Dragon, with a white ſpreading Flower.
11. ANTIRRHINUM *majus ſaxatile, anguſtiſſimis foliis, flore purpuraſcente minori. Bar. Icon.* Greater Rock Snap-Dragon, with very narrow Leaves, and a leſſer purple Flower.
12. ANTIRRHINUM *Creticum anguſtifolium, flore maximo purpureo. Tourn. Cor.* Narrow-leav'd Snap-Dragon of *Crete*, with the largeſt purple Flower.

The four firſt Sorts are raiſed from Seeds, which ſhould be ſown in a dry Soil, which is not too rich, in *April* or *May*; and in *July* may be planted out into large Borders, where they will flower the Spring following; or they may be ſown early in the Spring, for flowering the ſame Autumn; but then they are not ſo likely to endure the Winter; and if the Autumn prove bad, they will not perfect their Seeds.

Theſe Plants grow extremely well upon old Walls or Buildings, in which Places they will endure for ſeveral Years; whereas thoſe planted in Gardens ſeldom laſt longer than two Years, unleſs they are planted in a very poor Soil, and the Flowers often cropp'd, and not ſuffer'd to feed: but any of theſe Sorts may be continued, by planting Cuttings in any of the Summer Months, which will eaſily take Root. The fourth Sort is tenderer than any of the former, and ſhould therefore be planted in Pots fill'd with rubbiſhing dry ſandy Soil, and ſhelter'd in Winter under a common Hot-bed Frame, obſerving to give them free open Air, by taking off the Glaſſes in mild Weather, and only covering them in very wet, or froſty Weather.

All the Sorts of Snap-Dragons are pretty Ornaments in a Garden, and requiring very little Culture, renders them more acceptable. They are all hardy Plants, and will reſiſt the Cold of our Winters extremely well, eſpecially if they are planted on a dry, gravelly or ſandy Soil; for when they are planted in a rich moiſt Soil, they will grow very luxuriant for a time, but are very ſubject to rot in Autumn or Winter, and are much more ſuſceptible of Cold, than when they are in a dry hungry, rocky Soil: So that theſe Plants may be placed amongſt Stones, or they will grow in the Joints of old Walls, where they may be placed ſo as to render ſome abject Parts of a Garden very agreeable, for they will continue in Flower ſeveral Months; and if the Seeds are permitted to ſhed, there will be a continual Supply of young Plants, without any Trouble.

Where-ever theſe Plants are deſigned to grow on Walls, or on a rocky barren Soil, the Seeds ſhould be ſown the Beginning of *March*, where they are deſigned to remain; (for if the Plants are firſt raiſed in a better Soil, and afterward tranſplanted into thoſe Places, they ſeldom ſucceed well). When the

Plants are come up, they will require no other Culture but to keep them clear from Weeds, and where they come up too thick, to pull ſome of them out, ſo as to give them room to grow. In *July* theſe Plants will begin to flower, and will continue flowering till the Froſt prevents them. Theſe Plants which grow on Walls, will be ſtrong, and have woody Stems, which will continue two or three Years.

APARINE, [this Plant is ſo called, becauſe it is very rough: It is called *Philadelphos* and *Philanthropon* of φιλέω, I love, and ἄνθρωπος, a Man; becauſe if a Perſon walks in uncultivated Places, the Plant not only applies itſelf to his Garments, but it holds them, as if it had a mind to bind a Man with an amiable Band: It is alſo called *Omphalocarpon*, of ὀμφαλὸς, a Navel, and καρπὸς, Fruit, becauſe the Seeds reſemble a Navel] Gooſe-graſs *or* Clivers.

This Plant grows wild almoſt every where, the Seeds ſticking to the Cloaths of People that paſs by where they grow: It is ſometimes uſed in Medicine, but is too common a Weed to be admitted into a Garden.

APETALOUS Plants, [of α Priv. and πέταλον, a Flower-leaf, *Gr.*] are ſuch as have no Flower-leaves.

APHACA; Vetchling.

The *Characters* are;

It hath a Butterfly Flower, out of whoſe Empalement riſes the Pointal, which afterwards becomes a Pod, full of roundiſh Seeds. To theſe Notes muſt be added, that two Leaves only grow at the Joints of the Stalks, out of whoſe Wings proceed the Tendrils.

We have but one *Species* of this Plant, (*viz.*)

APHACA. *Lob. Icon.* Yellow Vetchling.

This Plant is found wild in divers Parts of *England*, on arable Land, but is ſeldom preſerved in Gardens. It is an annual Plant, which periſhes ſoon after the Seeds are perfected. The ſureſt Method to cultivate this Plant, is to ſow the Seeds on a Bed of light Earth in Autumn, ſoon after they are ripe; for if they are kept out of the Ground until Spring, they ſeldom grow; and if ſome of the Plants do come up at that Seaſon, they ſeldom perfect their Seeds ſo well as thoſe which were ſown in Autumn. Theſe Seeds ſhould be ſown where the Plants are deſigned to remain; for they ſeldom ſucceed well, if they are tranſplanted. All the Culture theſe Plants require, is to keep them clear from Weeds, and to thin them where they come up too cloſe, leaving them about ten Inches or a Foot aſunder.

APICES, [of *Apex*, *Lat.* a Top or Point] are thoſe little Knobs that grow on the *Stamina* in the Middle of the Flower: they are commonly of a dark purpliſh Colour; they have been diſcovered, by the help of Microſcopes, to be, as it were, a ſort of Seed-veſſels, containing in them ſmall globular or oval Particles of various Colours, and exquiſitely formed: they are by ſome ſuppoſed to be a kind of Male Sperm, which falling down into the Flower, fecundates and ripens the Seed.

APIOS, [is ſo called of Ἄπιος, a Pear, becauſe its Root reſembles a Pear] the knobbed-rooted *Virginian* Liquorice Vetch.

The *Characters* are;

It hath a climbing Stalk; the Leaves grow almoſt oppoſite, and faſtened, as it were, to the Mid-rib; the Root is tuberous.

There is, at preſent, but one *Specie* of this Plant known to us; which is,

APIOS *Americana, Cornuti.* The American Apios of *Cornutus.*

This Plant hath large knobbed Roots, which part as they grow old, by which means the Plant is increaſed; for it rarely produces ripe Seeds with us: It is hardy, and will endure the Cold in the open Ground, if planted in a dry Soil; but is ſubject to rot with too much wet in Winter: It dies to the Root every Autumn, and riſes again the ſucceeding Spring, and will twiſt itſelf round a Pole, and grow to the Height of eight or ten Feet, and produce in *July* fine Spikes of Flowers: It hath alſo been planted near Arbours, where it hath covered them very well towards the latter End of Summer, but is cut down with the firſt Cold of Autumn.

APIUM, [*Apium* is ſo called, as ſome ſay, of *Apes*, Bees, becauſe Bees are ſaid to be delighted very much with it; or of *Apex*, becauſe the Ancients made Crowns of it to adorn the Head: It is called *Eleoſelinum*, of ἕλος, a Marſh, and σέλινον; and *Paludapium*, of *Palus* and *Apium*] Parſley.

The *Characters* are;

The Leaves are divided into Wings, or grow upon a branched Rib, and are, for the moſt part, cut into ſmall Segments: the Petals of the Flower are whole, and equal; each Flower being ſucceeded by two gibbous channell'd Seeds.

The *Species* are;

1. APIUM *hortenſe ſeu petroſelinum, vulgo. C. B. P.* Common Garden Parſley.
2. APIUM *vel petroſelinum criſpum. C. B. P.* Curled Parſley.
3. APIUM *hortenſe latifolium. C. B. P.* Broad-leav'd Garden Parſley.
4. APIUM *Luſitanicum rotundifolium. Inſt. R. H.* Round-leav'd *Portugal* Parſley.
5. APIUM *hortenſe latifolium, maxima craſſiſſima ſuavi et eduli radice. Boerh.* Broad-leav'd Garden Parſley, with a large ſweet eatable Root.
6. APIUM *paluſtre, & Apium officinarum. C. B. P.* Smallage.
7. APIUM *dulce*, CELERI *Italorum. H. R. Par.* Celeri.
8. APIUM *dulce degener, radice rapacea. Jeſſieu.* Turnep-rooted Celeri, commonly call'd *Celeriac*.
9. APIUM *Macedonicum. C. B. P.* The *Macedonian* Parſley.
10. APIUM *Luſitanicum maximum, folio trilobato, flore luteolo. Boerh. Ind.* Great *Portugal* Parſley, with a trilobated Leaf, and a yellowiſh Flower.
11. APIUM *Pyrenaicum, thapſiæ facie. Inſt. R. H.* Pyrenean Parſley, with the Face of the Deadly Carrot.
12. APIUM *montanum, ſive petræum album. J. B. Raii* White Mountain Parſley.
13. APIUM *montanum, ſive petræum album elatius.* Taller white Mountain Parſley.
14. APIUM *Aniſum dictum, ſemire ſuaveolenti majore. Tourn.* Parſley with large ſweet-ſcented Seeds, *commonly called* Aniſe.

The common Parſley muſt be ſown early in the Spring, for the Seeds remain a long time in the Earth, the Plants ſeldom appearing in leſs than ſix Weeks after ſowing the Seeds. This Sort is generally ſown in Drills by the Edges of Borders in the Kitchen-garden, becauſe it is much eaſier to keep it clear from Weeds, than if the Seeds are ſown promiſcuouſly on a Border, and the Parſley is ſoon cut. But if the Roots are deſired for Uſe, then the Seeds muſt be ſown thin, and when the Plants are come up, they ſhould be houghed out ſingle, as is practiſed for Carrots, Onions, *&c.* obſerving alſo to cut up the Weeds; if this be obſerved, the Roots will become fit for Uſe by *Auguſt*.

All the Sorts of Parſley are biennial Plants, ſeldom continuing longer than two Years, ſo that there ſhould be a freſh Supply ſown every Year; for that which comes up one Year, will be fit to cut by *June* the ſame Seaſon, and will continue all the following Winter and Spring fit for Uſe; but in *June* it will run up to Seed, after which time it is not ſo good for Kitchen Uſe; but by that Seaſon the young Parſley which was ſown in the Spring, will be fit to cut. The beſt Time to cut the common Parſley to diſtil, is in *July*, when it will be full in Flower.

The curled Parſley is ſown in ſome curious Gardens, for garniſhing Diſhes; the Leaves being curiouſly furbelowed, anſwer this Purpoſe very well, and the Herb is equally as good for Uſe as the Common, it being only a Variety thereof. In order to have this large and fine, it ſhould be ſown very thin, or when it firſt comes up, hough it out to the Diſtance of four Inches ſquare; by which Management your Leaves will be extremely large and fair, and, if you do not ſuffer it to ſeed, will endure three Years very well; but if it ſeeds, it will ſeldom continue good after.

The great Garden Parſley is, at preſent, little known to us in *England*; but in *Holland* it is very common in all their Markets: they bring theſe Roots in Bunches, as we do young Carrots, to Market, in Summer; and the Roots are much of the ſame Size: It is call'd *Petroſeline Wortle* by the *Dutch*, who are very fond of it.

It may be cultivated by ſowing the Seeds in good Ground early in the Spring, and in *April*, when the Plants are up, cut them out with a Hough, (as is practiſed for young Carrots) to above five or ſix Inches ſquare, and keep them conſtantly clean from Weeds, and in *July* the Roots will be fit to draw for Uſe, and may be boiled and eaten as young Carrots, and are very palatable and wholeſome, eſpecially for thoſe who are troubled with the Gravel.

But if theſe Plants are cut out, to allow them more Room, if the Soil is good, the Roots will grow to the Size of a middling Parſnip by *September*: The Roots are much uſed to make a *Dutch* Diſh called *Water Souche*.

The *Macedonian* Parſley is a Stranger in our Country, and not to be found except in curious Botanick Gardens: This Plant is propagated by ſowing the Seed, in the Spring of the Year, in an open well-expoſed Bed of freſh Earth; and in the Summer, when the Plants are come up, they ſhould be tranſplanted, ſome of them into Pots, filled with freſh light Earth, and others into a well-ſhelter'd dry Border, where they may remain until they flower, which is not before the ſecond, and ſometimes the third Year; but thoſe that were planted in Pots, ſhould be ſheltered, during the Winter Seaſon, under a Hot-bed Frame, giving them free open Air whenever the Weather is mild. Theſe Plants, in the Spring following, may be turned out of the Pots into the full Ground, that their Seeds may be the better maturated.

The Aniſe is a very difficult Plant to make grow with us; for although we have freſh Seeds from Abroad, which will often come up very well, yet if there happens but a little wet or cold Weather in the Summer-time, the Plants will rot off and die away. The beſt Method is to raiſe the Plants upon a moderate Hot-bed early in the Spring; and when they are come up, prick them out again upon another Bed that hath a little Warmth, obſerving to expoſe them to the open Air by degrees, by which means they will have more Strength, and conſequently be in leſs danger of being hurt by bad Weather: but this Plant is not worth propagating for Uſe in *England*, ſince we can have the Seeds much better, and at a cheaper Rate, from *Italy*, than they can be produced here.

Smallage is a common Weed, by the Side of Ditches and Brooks of Water, in moſt parts of *England*, ſo that it is ſeldom cultivated in Gardens; but if any Perſon is willing to propagate it, the Seeds ſhould be ſown ſoon after they are ripe, on a moiſt Spot of Ground; and when the Plants are come up, they may be either tranſplanted into a moiſt Soil, or houghed out, and left ſix or eight Inches aſunder, where they may remain for good. The Seed of this Plant is one of the leſſer warm Seeds, and both that and the Herb is uſed in Medicine.

The two Sorts of *Celery* are treated under that Article, they being better known by their common Names uſed in the Kitchen, than by their Botanical Names.

The other Sorts of Parſley are preſerved in curious botanick Gardens, but as they are Plants of no Uſe, ſo they are ſeldom propagated in other Gardens. Theſe may be propagated as the common Sort, but the Plants growing much larger, ſhould be left at a greater Diſtance.

APOCYNUM, ['Απόκυνον, of ἀπὸ and κυνὸς, of a Dog, becauſe the Antients believed this Plant would kill Dogs. The *Egyptians* call this Plant *Oſſar*, whence comes the Name of the Fruit *Bideſſar*, as tho' *Bordes Oſſar*, which in the *Arabic* Tongue ſignifies the Egg *Oſſar*.] Dogs-bane.

The *Characters* are;

The Leaves are produced oppoſite, by Pairs, upon the Branches; the Flower conſiſts of one Leaf, which is cut into ſeveral Segments; from its Flower-cup ariſes the Pointal, which is fixed like a Nail in the back Part of the Flower, and is afterwards changed into a Fruit, which is, for the moſt part, compoſed of two Capſules, or Pods, which open from the Baſe to the Top, incloſing many Seeds, which have a long pappous Down adhering to them: to this may be added, that the whole Plant abounds with a milky Juice.

There are ſeveral Sorts of this Plant cultivated in the curious Gardens of Plants, ſome of which are very beautiful, and deſerve a Place in every good Garden. I ſhall mention the different Species of this Plant, which are cultivated in the *Engliſh* Gardens, and ſhall leave the Reader to ſelect ſuch of them as he ſhall fancy to cultivate.

1. APOCYNUM *erectum, latifolium, incanum, Syriacum, floribus parvis obſolete purpuraſcentibus. Par. Bat.* The upright broad-leav'd hoary *Syrian* Dogs-bane, with purpliſh colour'd Flowers.

2. APOCYNUM *erectum Canadenſe, anguſtifolium. Par. Bat.* The upright narrow-leav'd *Canada* Dogs-bane.

3. APOCYNUM *erectum Canadenſe, latifolium. Par. Bat.* The broad-leav'd upright *Canada* Dogs-bane.

4. APOCYNUM *Americanum, foliis androſæmi majoris, flore lilii convallium ſuave-rubentis. H. R. P.* The *American* Dogs-bane, with Tutſan Leaves, and red Flowers, like the Lily of the Valley.

5. APOCYNUM *erectum, fruticoſum, folio ſubrotundo viridante. Par. Bat.* The ſhrubby upright Dogs-bane, with roundiſh green Leaves.

6. APOCYNUM *erectum, Africanum, folio ſalicis anguſto glabro, fructu villoſo. Par. Bat.* The upright Willow-leav'd *African* Dogs-bane, with hairy Fruit.

7. APOCYNUM *Afrum, ſcandens, folio rotundo, ſubincano, nummulariæ. Boerh.* The *African* creeping Dogs-bane, with Leaves like *Monywort*.

8. APOCYNUM *erectum, folio oblongo, flore umbellato, petalis coccineis reflexis. Sloan. Cat.* The upright Dogs-bane, with oblong Leaves, and Scarlet Flowers, called by ſome *Baſtard Ipecacuana*.

9. APOCYNUM *Canadenſe, anguſtifolium, flore aurantii. Mor. Præl.* The narrow leav'd *Canada* Apocynum, with Orange-colour'd Flowers.

10. APOCYNUM *Marylandicum, erectum, folio ſubrotundo, flore ruberrimo.* The upright *Maryland* Dogs-bane, with roundiſh Leaves, and deep red Flowers.

The firſt of theſe *Dogs-banes* is a prodigious Creeper at the Root, and will in a ſhort Time overſpread a large Compaſs of Ground, and muſt never be planted too near other Plants or Flowers, which would be over-run by this Plant, and deſtroyed; but it may have a place in ſome obſcure Part of the Garden; for it is extremely hardy, and will thrive in almoſt any Soil or Situation: It grows to be ſix or ſeven Feet high, and produces large Umbels of Flowers, which have a ſtrong ſweet Smell, but are of a poiſonous Nature, as are all the true *Apocynums*, and therefore ſhould not be planted in the Way of Children, who may receive Damage by breaking any part of the Plant, and letting the milky Juice, with which they abound, run upon the tender Part of their Fleſh, which will be apt to bliſter it; theſe Flowers are ſometimes ſucceeded by large oblong Pods, which contain a great Quantity of a ſoft Cottony Subſtance, that adheres to the Seeds, and are of Service to tranſport them to a Diſtance when ripe. This Plant dies to the Root in Winter, and riſes again the ſucceeding Spring.

The ſecond, third, fourth, and tenth Sorts are all of them very hardy, and may be planted in the open Ground, but muſt have a dry Soil; theſe all of them produce large fine Flowers, and are propagated by parting their Roots in *March*, after the cold Weather is paſt; for they ſeldom produce ripe Seeds with us.

The fifth, ſixth, ſeventh, and eighth Sorts are tender, and muſt be preſerved in Pots, and houſed in Winter.

The fifth and ſixth Sorts will grow very ſhrubby, and ſometimes to the Height of eight or nine Feet, and do produce Bunches of Flowers, which in the ſixth Sort are of a whitiſh green, and the fifth of a worn-out purple Colour, but are of no great Beauty or Smell. Theſe are increaſed by planting Cuttings in any of the Summer Months, in Pots of light ſandy Earth, plunging them into a moderate Hot-bed, and ſhading them from the great Heat of the Sun, giving them gentle Refreſhings of Water. Theſe muſt have a good Green-houſe in Winter, and muſt not have too much Water in that Seaſon.

The ſeventh Sort is a climbing Plant, and will twiſt itſelf round a Stake, and grow to the Height of ſeven or eight Feet, and in Summer will produce from the Joints ſmall Umbels of worn-out purple-colour'd Flowers, which are extremely ſweet. This is propagated by laying down the young Shoots, which do eaſily take Root, or by parting the Roots of the old Plants.

The eighth Sort is the moſt tender of them all, and requires a moderate Stove to preſerve it in Winter; this produces extreme beautiful Orange-colour'd Flowers, which often are ſucceeded by ripe Seeds: This Plant may be increaſed by planting the Cuttings in *June*, in a moderate Hot-bed, but muſt have little Water, and be ſecured from the violent Heat of the Sun, and the Cold of the Nights: but the beſt way to propagate them, is by ſowing the Seeds in a Hot-bed in *March*; and when the Plants are come up, prick them into ſmall Pots, and plunge them into another Hot-bed, to bring them forward; and in *June* you may begin to expoſe them to the open Air, at which Time they will begin to flower; but it will be adviſeable to preſerve one or two of the ſtrongeſt in the Hot-bed, in order to procure good Seeds.

The ninth Sort is tolerably hardy, and only requires to be ſcreen'd from the extreme Cold in Winter; and I believe, if it were planted into the full Ground, under a warm Wall, it would do very well; but as I have not yet tried it, ſo I can't affirm it will do: This Plant produces beautiful Umbels of Orange-colour'd Flowers, which abide moſt part of the Month of *Auguſt*, and deſerve a Place in the moſt curious Garden. This is propagated by parting the Roots in *March*, or ſowing the Seeds, which in a good Seaſon do ripen tolerably well with us.

APPLE-Tree, by the *Latins* called *Malus*.

The *Characters* are;

The Fruit of this Tree is, for the moſt part, hollowed about the Foot-ſtalk; the Cells in which the Seeds are lodged, are ſeparated by cartilaginous Partitions; the Juice of the Fruit is ſowerish; and the Tree is large and ſpreading: to this may be added, the Flowers conſiſt of five Leaves, which expand in Form of a Roſe.

There are a great Variety of theſe Fruits propagated in *England*, either for the Kitchen, the Deſert, or to make Cyder: I ſhall mention the moſt curious Sorts for each Purpoſe, omitting the ordinary Kinds, as not worth naming, and ſhall then proceed to their Culture and Management.

Herefordſhire Underleaf.
John Apple; or, *Deux-Annes.*

The ſeveral Sorts of *Apples* are planted, either as Standards, in Orchards or Gardens, or Dwarfs, or in Eſpaliers, and ſometimes againſt Walls: Thoſe that are deſigned for Standards, ſhould be grafted on Crab-ſtocks, which are much hardier, and of longer Duration than any other Sort of *Apple*; but thoſe that are deſigned for Dwarfs, or Eſpaliers, may be grafted either on the Paradiſe-ſtock, Codling, or any other Sort of Apple-ſtock, that doth not ſhoot too freely. The Manner of *Grafting* will be deſcribed under its proper Article; and the Manner of raiſing and managing the Stocks, will be explained in the Article of *Nurſeries*, to which I refer the Reader, and proceed to the Manner of planting them out for good.

If you intend to make a new Orchard, the Soil ſhould be plough'd; if a Green-ſward, at leaſt twice before planting, that the Earth may be mellowed, and imbibe the nitrous Particles of the Air, and that the Turf may be well rotted and mixed with the Earth; but if it hath been plough'd Ground, one good Ploughing will be ſufficient.

The beſt Seaſon for planting theſe Trees, if the Soil is dry, is in *October*, as ſoon as the Leaves begin to decay; but in a wet Soil, it is beſt to defer it till *February*.

The Diſtance theſe Trees ought to be planted, is at leaſt forty Feet ſquare, that the Sun and Air may freely paſs to every Part of the Tree, to diſſipate all crude and unhealthy Vapours, which are either exhaled from the Earth, or produced from the Perſpiration of the Trees, and are, many Times, the Cauſe of Blights; or are, at leaſt, abſorbed again by the Trees, when in a State of Reſpiration, and muſt occaſion the Fruit to be crude and ill-taſted, which is too often attributed to the Soil, when the only Cauſe of it may be their being too cloſely planted. This Diſtance many People will, perhaps, think too much; but I dare ſay, it would be ſtill better, could they be allowed eighty Feet Diſtance, Row from Row, and forty Feet in the Rows; nor would I adviſe the planting of Cherries, or any other Sort of Fruit-Trees between them, till they are arrived to an Age of Maturity; but rather, that the Ground between them ſhould be ploughed and tilled with Corn, or any other Crop, as if it were intirely open; and it hath been experienced by ſeveral People in *Herefordſhire*, and other Counties in *England*, that their Crops have been exceeding good, and their Trees much improved by the turning of the Soil; for want of which Culture, together with their cloſe ſtanding, we find vaſt Numbers of Orchards that have ſcarcely a healthy Tree in them, the greateſt Part of them being either cankered, or covered over with Moſs; and how can we ſuppoſe to eat kindly Fruit from diſtemper'd Trees? We may with as much Juſtice affirm, that a diſtemper'd Woman will give healthy Milk; which I believe no one will dare to affirm, tho' there is equally the ſame Probability in both.

And ſince I am upon this Article of cloſe Planting, ſuffer me to make a little Digreſſion, not altogether foreign to our preſent Purpoſe; which is, to take Notice of a prevailing Error, in planting of Fruit-Gardens, like Wilderneſs Trees or Flowering Shrubs, cloſe together, and mixing the different Sorts of Fruits in each Diviſion, in ſuch a Manner, that no two Trees of the ſame Kind ſhall ſtand near each other, ſuppoſing each Tree to draw different Particles from the Ground for their Nouriſhment, and ſuffering them to grow, as they are naturally diſpoſed, without ever pruning them, hereby hoping to have great Quantities of Fruit, with very little Trouble after the firſt planting.

Now granting this laſt Suppoſition to be true, (tho' I am fully convinced of the contrary) yet how abſurd is it to think, that what little Fruit may be produced in this Way, can be equally ſo good or wholſome, as thoſe which are the Product of healthy Trees, and have the Advantages of a free Air, and the Benefit of the kindly Sun, to correct and diſſipate the Crudities of the Earth round the Roots, as alſo thoſe moiſt Vapours which are almoſt continually perſpiring from the Trunks, Branches, and Leaves of theſe Trees, which, for want of the Air's free Admittance, are conſtantly hovering about the Trees in theſe Plantations; and in cold Weather, or the Night-time, when the Trees are in a State of Reſpiration, theſe rancid Vapours are imbibed thro' the Pores of the Leaves, and mixed with the Juices, and are protruded thro' the Veſſels, and enter the Fruits, whereby they muſt be render'd ill-taſted and unwholſome.

But as this Practice was introduced by ſome Perſons who were intirely ignorant of what they undertook, and ſet out upon wrong Principles of Philoſophy, ſo I hope, the Gentlemen to whom this Method may be propoſed, will be ſo kind to themſelves, as to wait a little, and ſee the Effect of thoſe Plantations already made, before they ſet on foot ſo wild a Project.

Indeed, I am aware how many Enemies I ſhall raiſe, by retrenching the great Demand for Fruit-trees, which muſt of Neceſſity be made in the ſeveral Nurſeries in *England*, if this Practice be continued; but as I ſhall, thro' the whole Book, deliver my Sentiments freely, on every Article here treated of, aiming at nothing more than the Information of my Readers, ſo I hope there will be found none of my Profeſſion of ſuch mercenary Tempers, as to condemn me for telling Truth, tho' it may not always exactly agree with their preſent Intereſts: But enough of this at preſent; let us now return to our Planting.

When the Seaſon for Planting is come, as was before directed, we muſt make Choice of good thriving Trees, of about three Years grafting, but by no means chuſe old Trees, as is the Practice of ſome, thinking thereby to ſave time; whereas a young thriving Tree will, in three or four Years after planting, overtake one of theſe old ones, and make far better

Trees in a few Years, than they ever will do: nor ſhould you take Trees from a rich Soil, to plant into a poor one; or from a wet Soil, for a dry one; but endeavour, if poſſible, to have your Trees from a Soil as near in Quality to your own as poſſible, or rather, from one that is not quite ſo good as yours.

In preparing theſe Trees for planting, cut off all broken or bruiſed Roots, or ſuch as croſs and gall each other; as alſo all ſmall Fibres, which rarely ſurvive a Remove, (unleſs the Trees are planted immediately after taking up, before the Wind has dried them) and are very ſubject to mould and rot, and are often prejudicial to the new Roots, by obſtructing their Progreſs, and many times deſtroy them ſoon after they are produced, by the ſpreading of the Mouldineſs which they had taken quite round the older Roots: You muſt alſo at the ſame time take off ſome of the moſt luxuriant Branches, and ſhorten others, ſo as to reduce the Head to a handſome Figure, and moderate Size; but by no means cut and lop the Head in ſuch an unmerciful manner as ſome do; for a moderate Proportion of Head is abſolutely neceſſary to furniſh Nouriſhment to the Roots, until new ones are produced to ſupply the Heads, and the making large Wounds at both Parts of the Tree at the ſame Time, muſt be very hurtful. Your Trees being thus prepared, make a Hole with a Spade where each Tree is to ſtand, about two Feet deep, more or leſs, according to the Size of their Roots; and ſo likewiſe in Width, according to the ſame Proportion, making it level in the Bottom, and breaking all hard Clods; then place the Tree in the Center of the Hole, as upright as poſſible; and while one Perſon keeps the Tree in its right Poſition, another ſhould, with a Spade, break the Earth, and lay it in between the Roots, ſhaking the Tree, the better to let the Earth fall between every Root, that there may be no Cavity left: then with your Feet gently preſs the Earth down, to faſten and ſettle the Tree; and if the Weather prove dry, it will not be amiſs to give each Tree a good Watering, which will fix the Earth to them, and greatly forward their Production of new Roots: You ſhould alſo, if the Heads of the Trees are large, fix a Stake to each Tree, to prevent their being ſhaken with the Winds, which would diſturb and greatly injure the new Roots: and if the Seaſon after planting ſhould prove very dry, you muſt repeat your Waterings; but do not over-water them, which is a Fault many People are guilty of; for too much Wet rots all the new Roots, which are very tender for the firſt and ſecond Years, and very ſubject to Damages during that Time; but if you can conveniently procure a Quantity of Green-ſward, pared from a Common, &c. and lay a little of it round the Foot of each Tree, ſo as to cover the Surface about three Feet round the Stem, with the Graſs downwards; this will preſerve the Ground from drying too faſt, and render one Watering of more Service than three or four would otherwiſe be. The next Winter, after planting, this Turf will be rooted; you ſhould therefore, early in *February*, when the great Froſts are over, gently dig up the Ground about each Tree, burying this rotten Turf in the Bottom, which will keep the Ground looſe, and greatly promote the Growth of the Trees. An Orchard or Garden thus planted, and manag'd, will afford the Owner no ſmall Pleaſure, by the Advance the Trees will make, and muſt as greatly redound to his Profit.

I ſhall now proceed to give Directions for planting *Dwarfs*, either for Standards or Eſpaliers; tho' I muſt own, Dwarf Standard-trees are what I ſhould never adviſe any Perſon to plant; for their Heads do, in time, grow ſo large, that there is no getting near their Stems, ſo that the Ground between them is wholly uſeleſs for any Purpoſe; nor can the Sun reach to warm the Ground, and diſſipate crude Vapours, ſo that the Fruit can never be ſo well-taſted as thoſe produc'd from Eſpaliers, which enjoy all the Advantages of Sun and free Air; but if you are determin'd to have Dwarf-trees, you muſt allow them a large Diſtance from each other; twenty-four Feet ſquare is the leaſt they ſhould be planted; and when the Trees begin to make Shoots, they muſt be faſten'd down to Stakes, drove into the Ground all round the Tree, as horizontally as poſſible; for if you ſuffer the Branches at firſt to grow upright, you can never after reduce them to a proper Figure, without either quite cutting down the Branches, or plaſhing and mangling them ſo much as often to canker and decay the Tree. In pruning theſe Trees, great Care ſhould be taken to keep their middle Part as free from Wood as poſſible, and not ſuffer their Branches to croſs each other: The farther Particulars I ſhall refer to the pruning of *Eſpaliers*, which will alſo agree for *Dwarfs*, excepting what I have already mention'd.

Eſpaliers are commonly planted to ſurround the Quarters of a Kitchen-Garden, in which Place they have a very good Effect, if rightly planted and manag'd, rendring it not in the leaſt inferior to the fineſt *Parterre*, or moſt finiſh'd Pleaſure Garden: For what can be more agreeable than to walk between regular Hedges of Fruit-trees, which early in the Spring are cover'd with beautiful Flowers, and in Summer and Autumn, are charg'd with noble Fruits of different Kinds; and the Kitchen Stuff in the Quarters are intirely hid from Sight, and alſo ſcreen'd from the Injuries of Weather?

In the Diſtribution of the Quarters, I would adviſe that they are not too ſmall, which renders them unfit for many Sorts of Kitchen Stuff, and alſo occaſions your Eſpaliers to be too near each other, which ſhould always be avoided: The Extent of theſe Quarters ought to be in Proportion to the Bigneſs of the Garden; in a large Ground they may be two hundred and fifty Feet ſquare, or three hundred Feet long, and one hundred Feet broad, according to the Figure of the Garden; and in ſmall Gardens one hundred Feet ſquare is as much as can be allowed, and the Walks between the Eſpaliers ſhould alſo be in breadth according to the ſame Proportion. When your Ground is prepar'd for Planting, you ſhould endeavour to make Choice of Trees which ſhoot nearly alike, to plant in each Eſpalier, by which means you may the better proportion their Diſtances, in order to have the Eſpaliers of an equal Height, and not to intermix weak-ſhooting Trees amongſt the moſt luxuriant, which would occaſion a very unſightly Hedge.

The Diſtance theſe Trees ſhould be planted, if on Crab or Free Stocks, ſhould be, for large ſhooting Trees, twenty Feet, and for the weaker, ſixteen; but if they are on Paradiſe Stocks, ten or twelve Feet will be ſufficient: The Manner of preparing and planting theſe Trees being the ſame with thoſe before-mention'd, I ſhall not repeat it, but refer the Reader thereto; but only ſhall obſerve here, that it will be proper to head theſe Trees to about four Eyes above the Graft, and never to chuſe Trees more than two Years old from the Time of Grafting; for older Trees are not ſo ſubject to break out when headed, their Bark being for the moſt part hard and the Wounds given to old Trees are not ſo ſoon healed as in young ones.

The Summer following, you muſt provide a Parcel of ſmall Stakes, of about three Feet long, to drive into the Ground on each Side of your Trees; four to each Tree will be ſufficient; to theſe Stakes you muſt faſten the new Shoots, as they are produced, as horizontally as poſſible, and not ſuffer them to grow upright, as is the too common Practice of many; for the Branches being thus train'd in Summer, will want no Force or Violence to be uſed in Winter to bring them to their proper Places, nor will their Shoots be ſo groſs and ſtubborn.

If the Trees have taken kindly, it is very probable that all the four Eyes have produced Shoots; if ſo, at *Michaelmas* (which I would fix for the Time of Pruning) cut the two uppermoſt Shoots to four Eyes each, in order to furniſh your Tree with Branches, but the two undermoſt may be left ſix or eight Joints in Length, in Proportion to their Strength; but let me lay it down for a Rule, never to ſhorten any Shoots in Summer, unleſs it be to furniſh Branches to fill up a Vacancy in the Eſpalier, and this ſhould never be done after *May*; for Shoots which are produced after *Midſummer*, are never duly ripened and prepared, ſo can never be proper, either for the Production of Wood or Fruit.

But if your Trees have made but three Shoots the firſt Summer, then at *Michaelmas* ſhorten the uppermoſt to three Eyes, leaving it upright in the Middle of the Tree, and ſhorten the two Side-Branches to five or ſix Eyes, in Proportion to their Strength, training them as horizontally as poſſible; and if they ſhould have produced but two Shoots the firſt Year, then it would be adviſeable to ſhorten both of theſe to four Eyes each, for Reaſons before given.

The ſecond Year you muſt obſerve to train in all new Shoots horizontally, as in the firſt, and to diſplace all fore-right Shoots, which will not come handſomely into the Eſpalier, as faſt as they are produced, that they may not exhauſt the Nouriſhment of the Tree: At *Michaelmas* ſhorten the Shoots in the middle Parts of the Tree, or where Branches are wanted to fill up Vacancies; but for ever after be cautious of unmerciful lopping or ſhortning of Branches; for the more you cut, the more they ſhoot, and there is no Way ſo ſure in the Management of all Fruits, which bear on old Wood, as to leave their Branches at full Length, where the Tree is fully ſupply'd with Wood, training them as horizontally as may be, which will prevent their luxuriant ſhooting; beſides, in many Sorts of Fruits, the Bloſſom-buds are firſt produced at the Extremity of the laſt Year's Shoots, ſo that if they are cut off, you deſtroy the greateſt Part of your Crop.

Theſe few Rules, with diligent Obſervation, will be ſufficient for the well-regulating and managing your Eſpaliers, ſo as to reap both Profit and Pleaſure.

APPLES of LOVE; *vide* Lycoperſicon & Solanum.

MAD APPLES; *vide* Melongena.

APRICOCK *or* ABRICOT; *or*, in *Latin*, *Malus Armeniaca*.

We have in the *Engliſh* Gardens about eight Sorts of this Fruit cultivated; which are,

1. The *Maſculine Apricock*.
2. The *Orange Apricock*.
3. The *Algier Apricock*.
4. The *Roman Apricock*.
5. The *Turkey Apricock*.
6. The *Tranſparent Apricock*.
7. The *Breda Apricock*.
8. The *Bruxelles Apricock*.

Theſe Fruits are all propagated by budding them on Plum-ſtocks, and will readily take upon almoſt any Sort of Plum, provided the Stock be free and thriving, (except the *Bruxelles* Kind, which is uſually budded on a Sort of Stock commonly call'd the *St. Julian*, which better ſuits this Tree, as being generally planted for Standards, than any other Sort of Plum will do:) The manner of raiſing the Stocks, and budding theſe Trees, ſhall be treated of under their particular Articles, to which I refer the Reader, and ſhall proceed to their Planting and Management.

Theſe Trees are all (except the two laſt Sorts) planted againſt Walls, and ſhould have an *Eaſt* or *Weſt* Aſpect; for if they are planted full *South*, the great Heat cauſes them to be mealy before they are well eatable.

The Borders under theſe Walls ſhould be four Feet wide, at leaſt, and if it were more, the better; but I would never adviſe the making of them ſo deep as is the general Cuſtom; for if the Earth be two Feet deep, it is enough.

If your Ground is a wet, cold Loam or Clay, you ſhould raiſe your Borders as much above the Level of the Surface as it will admit, laying ſome Stones or Rubbiſh in the Bottom, to prevent the Roots from running downward; but if you plant upon a Chalk or Gravel, you muſt remove it to a conſiderable Width to make Room for a good Soil to be put in; but you need not go above two Feet deep at moſt.

The Soil, I would in general adviſe to be uſed for theſe and all other Sorts of Fruit-Trees, is freſh untry'd Earth from a Paſture Ground, taken about ten Inches deep, with the Turf, and laid to rot and mellow at leaſt twelve Months before it is uſed; and this muſt be kept often turn'd to ſweeten and imbibe the nitrous Particles of the Air.

Your Borders being thus prepared, make Choice of ſuch Trees as are but one Year's Growth from budding, and, if your Soil is dry, or of a middling Temper, you ſhould prefer *October* as the beſt Seaſon for Planting, eſpecially having at that Time a greater Choice of Trees from the Nurſeries, before they have been pick'd and drawn over by other People. The Manner of preparing theſe Trees for Planting being the ſame in common with other Fruit-Trees, I ſhall refer the Reader to the Article of *Apple-Trees*, where he'll find it largely treated of: But do not cut off any Part of the Head at that Time, unleſs there are any ſtrong fore-right Shoots, which will not come to the Wall, which may be taken quite away.

Your Trees being thus prepared, you muſt mark out the Diſtances they are to ſtand, which, in a good ſtrong Soil, or againſt a low Wall, ſhould be eighteen Feet or more; but in a moderate one, ſixteen Feet is a good reaſonable Diſtance; then make a Hole where each Tree is to ſtand, and place its Stem about four Inches from the Wall, inclining the Head thereto; and after having fix'd the Tree in the Ground, nail the Branches to the Wall, to prevent their ſhaking, and cover the Surface of the Ground round the Root with rotten Dung to keep out the Froſt; in this State let it remain till *February*, when, if the Weather is good, you muſt un-nail the Branches of your Trees, ſo as not to diſturb their Roots, and being provided with a ſharp Knife, put your Foot cloſe to the Stem of the Tree; and having plac'd your Left-hand to the Bottom of the Tree, to prevent its being diſturb'd, with your Right-hand, cut off the Head of the Tree, to about four or five Eyes above the Bud, ſo that the ſloping Side may be toward the Wall.

In the Spring, if the Weather proves dry, you muſt now and then give your Trees a gentle Refreſhing with Water; in the doing of which, if you obſerve to water them, with a Roſe to the Watering Pot, all over their Heads, it will greatly help them, and alſo lay ſome Turf, in the Manner directed for Apples, or ſome other Mulſh, round the Roots, to prevent their drying during the Summer Seaſon: As new Branches are produc'd, obſerve to nail them to the Wall in an horizontal Poſition; and ſuch Shoots as are produc'd fore-right, muſt be intirely diſplac'd. This muſt be repeated as often as is neceſſary to prevent their hanging from the Wall, but by no means ſtop any of the Shoots in Summer.

At *Michaelmas*, when the Trees have done growing, you muſt un-nail their Branches, and ſhorten them in proportion to their Strength; a vigorous Branch may be left eight or nine Inches long, but a weak one ſhould not be left above five or ſix. I ſuppoſe many People will wonder at this Direction, eſpecially having allow'd ſuch a Diſtance between the Trees, as believing by this Management the Wall will never be fill'd; but my Reaſon for it is, that I would have no Part of the Wall left unfurniſh'd with bearing Wood, which muſt conſequently be the Caſe, if the Branches are left to a great Length at firſt; for it ſeldom happens, that more Buds than two or three ſhoot for Branches, and theſe are for the moſt part ſuch as are the extreme Part of the laſt Year's Wood; ſo that all the lower Part of the Shoots becomes naked, nor will they ever after produce Shoots; and this is the Reaſon we ſee ſo many Trees which have their bearing Wood ſituated only in the extreme Part of the Tree.

When you have ſhorten'd the Shoots, be ſure to nail them as horizontally as poſſible; for upon this it is, that the future Good of the Tree chiefly depends.

The ſecond Summer obſerve, as in the firſt, to diſplace all fore-right Shoots, as they are produc'd, nailing in the other cloſe to the Wall horizontally, ſo that the Middle of the Tree may be kept open; and never ſhorten any of the Shoots in Summer, unleſs to furniſh Branches to fill vacant Places on the Wall, and never do this later than *April*, for Reaſons before given in the Article of *Apples*. At *Michaelmas* ſhorten theſe Shoots, as was directed for the firſt Year; the ſtrong ones may be left nine or ten Inches, and the weak ones ſix or ſeven at moſt.

The following Year's Management will be nearly the ſame with this; but only obſerve, that *Apricocks* produce their Bloſſom Buds, not only upon the laſt Year's Wood, but alſo upon Curſons or Spurs, which are produc'd from the two Years Wood; a great Care ſhould therefore be had in the Summer Management, not to hurt or diſplace theſe: Obſerve alſo, to ſhorten your Branches, at the Winter pruning, ſo as to furniſh freſh Wood in every Part of the Tree, and be ſure to cut out intirely all luxuriant Branches, or diſplace them as ſoon as they are produced, which would exhauſt the Nouriſhment from the bearing Branches, which, in my Opinion, can't be too ſtrong, provided they are kindly; for the more vigorous your Tree is, the more likely it is to reſiſt the Injuries of the Weather: And I have often ſeen Trees brought to ſo weak a Condition, as to be able only faintly to blow their Bloſſoms, and then moſt, or all of the bearing Branches have died; which has given Occaſion to the Owner to imagine it was the Effect of a Blight, when in reality, it was only for want of right Management. And I am fully perſuaded, half the Blights we hear complain'd of, proceed from nothing elſe but this.

Theſe few Rules, well executed, together with a little Obſervation and Care, will be ſufficient; and to pretend to preſcribe particular Directions for all the different Accidents, or manner of treating Fruits, would be impoſſible; but I believe the Reader will find what has been ſaid, if duly attended to, will anſwer his Deſign; for, without diligent Obſervation, there can be no ſuch thing as a ſkilful Manager, let him have never ſo many or good Inſtructions laid down to him.

The *Bruxelles* and *Breda Apricocks*, being for the moſt part planted for Standards, will require very little Pruning or Management, only obſerve to take out all dead Wood, or ſuch Branches as croſs each other; this muſt be done early in *Autumn*, or in the *Spring*, after the cold Weather is paſt, that the Part may not canker where the Inciſion is made.

The *Bruxelles* is by far the moſt delicious Fruit of all the *Apricocks*, and is greatly mended by growing on a Standard: It is ripe about the Beginning of *Auguſt*, and is of a middling Size.

APRIL.

Work to be done in the Kitchen-Garden.

In the Beginning of this Month make Ridges for Melons and Cucumbers, to be cover'd with Bell or Hand-glaſſes; which Work may be continu'd to the End of the Month, where large Quantities are requir'd: but thoſe made late, need not have ſo much Dung in them as the early ones. You ſhould, the middle of this Month, plant out the Melons which are to be rais'd under Paper.

You may ſtill ſow Sweet Marjoram, Thyme, Summer Savory, and other Aromatick Plants; which do not ſucceed, if they are ſown too early, eſpecially if the Spring be cold and wet.

Plant Kidney-Beans the Beginning of the Month in a warm Situation, and in dry Weather, for wet will deſtroy the Seeds in the Ground; and ſow Purſlain upon warm Borders, to come after that on the Hot-bed is gone.

Continue to hough your Crops of Radiſhes, Carrots, Parſnips, Onions, Leeks, *&c.* thinning them out to proper Diſtances; and cut down all the Weeds among them: This ſhould always be done in dry Weather, that the Weeds may be deſtroy'd. This ſtirring of the Ground between your Plants will be of great Service to promote their Growth and the Ground will be preſerv'd clear from Weeds.

In moiſt Weather plant Slips or Cuttings of Sage, Roſemary, Rue, Savory, Maſtick, Lavender, Stœchas, and other Aromatick Plants; for at this Seaſon they take Root very freely, eſpecially if they are ſhaded from the Sun, and duly water'd.

Plant Garden-Beans for a latter Crop, and continue ſowing the Marrow-fat and other large Kinds of Peaſe, to ſucceed thoſe which were ſown the former Month.

You may yet ſlip and plant Artichoaks upon a moiſt Soil; but if the Soil be dry, they will not do ſo well as thoſe which were planted the laſt Month. And now you ſhould plant out your Cauliflower-plants, which were rais'd in *February*, for a latter Crop.

Continue to ſow all Sorts of young Sallet-herbs, as Radiſh, Rape, Turnip, Muſtard, *&c.* every Week; for at this Seaſon they will ſoon be too large for uſe: But you ſhould obſerve, as the Heat of the Seaſon increaſes, to ſow them in a more ſhady Situation; for in Summer they thrive beſt on a North Border.

Sow ſome Cos, Sileſia, and other Kinds of large Lettuces, to ſucceed thoſe which were ſown the former Month: But theſe ſhould have a moiſt Soil, otherwiſe (if the Summer ſhould prove dry) they will not cabbage.

Tranſplant your young Celery-plants into Beds of rich Earth at about three Inches Diſtance, obſerving to water them duly until they have taken Root; but in doing of this, you ſhould not draw up all the Plants clean out of the Seed-bed, but only thin them, taking out the large ones, and leave the ſmaller Plants to get Strength.

Hough the Ground between your Rows of Beans and Peaſe, and draw the Earth up to their Stems, which will ſtrengthen them, and, by clearing the Ground from Weeds, the Plants will thrive the better.

After a Shower of Rain, draw the Earth up to the Stems of your Cabbage and Cauliflower-plants, which were planted either in Autumn, or early in the Spring. This is abſolutely neceſſary, to guard their Stems from the Sun and Wind, which dry and harden them but you muſt be careful in doing of this, not to draw the Earth up into their Hearts, which will deſtroy them.

Be careful to deſtroy Snails and Slugs, which at this Seaſon are invited abroad by gentle Showers of Rain, when they may be eaſily taken; for if they are ſuffer'd to remain, they will increaſe greatly, and become very troubleſome, and deſtructive to many of your Crops.

If the Nights prove cold, you muſt be careful to cover the Glaſſes over your early Cucumbers and Melons; for the young Fruit is very ſubject to drop off where the Beds are grown cool, or proper Coverings are wanting.

Sow Turnips on a moiſt Spot of Ground, to ſucceed thoſe which were ſown the laſt Month; and thoſe then ſow'd ſhould now be hough'd out to a proper Diſtance, and the Weeds between them deſtroy'd.

Your Beds of Mint, Tarragon, Parſley, *&c.* ſhould now be carefully weeded: for if the Weeds are permitted to get above the Plants at this Seaſon, they will draw them up weak, and ſpoil them. And if the Seaſon ſhould prove dry, they ſhould be water'd, which will greatly promote their Growth.

You may now plant Cuttings of Mint, Tarragon, *&c.* to make new Beds, the old ones often decaying, after they have ſtood two or three Years.

Tranſplant ſome of your Sileſia, Cos, and other large Kinds of Lettuces, which were ſown the former Month, obſerving to water them till they have taken Root.

The Cabbages and Savoys which were ſown the laſt Month ſhould now be thinn'd, and prick'd out into Beds, that they may acquire Strength before they are tranſplanted out for good; and the Seed-beds muſt be weeded, otherwiſe the Plants will draw up tall and weak.

The latter End of this Month you ſhould look over your Artichokes, and draw out all the young Plants which have been produced ſince the Stocks were ſlipp'd; for if theſe are permitted to grow, they will rob the Plants which were left for Fruit, and cauſe the Fruit to be ſmall. Some of the beſt of theſe Plants may be trimm'd and planted where there are any wanted to repair a young Plantation; but as theſe Plants do rarely produce Fruit the firſt Year, ſo they are ſeldom planted, except there be great want of them.

Products of the KITCHEN-GARDEN.

Sprout of Broccoli, Cabbages and Savoys are now very good, if they are gather'd before they run up to Seed. All Sorts of young Sallet-herbs, Spinach, Radiſhes, Aſparagus, Coleworts, ſome Parſnips and Carrots, where they have been preſerv'd in Sand; for where they have remain'd in the Ground, they will have ſprouted, after which their Roots will become ſticky and tough. Young Carrots, which were ſown in Autumn, are now in prime: Upon the Hot-beds Cucumbers, Peaſe, Kidney-Beans, and Purſlain: And toward the End of the Month you have Peaſe on warm Borders, and ſome Cabbage-Lettuces.

Work to be done in the FRUIT-GARDEN.

The Beginning of this Month you may graft ſome late Kinds of Fruit, provided the Seaſon be backward; but if the Spring is early, it will be too late for this Work.

Look carefully to your young Fruit-trees, obſerving to water them in dry Weather; and if you obſerve their Leaves beginning to curl up, you ſhould water them gently all over: This may be practis'd to great Advantage on old Trees, when you find their Leaves curling; but you muſt not do it in the Heat of the Day, leſt the Sun ſhould ſcorch their Leaves; nor too late in the Evening, eſpecially if the Nights are cold.

Thoſe Fruit-trees which were inoculated the laſt Summer, and have ſucceeded, ſhould have the Stocks cut down to three or four Inches above the Bud, (if it was not done the former Month) for now the Buds will begin to ſhoot.

Toward the End of this Month, you muſt begin to look over your Walls and Eſpaliers of Fruit-trees, training in the regular kindly Shoots, and diſplacing all fore-right and luxuriant ones, where they are produc'd. You may now thin your Apricocks, where they are too thick; for the ſooner this is done, the better thoſe will thrive which are left on.

Plant Cuttings of Vines in the Places where they are to remain, obſerving always to have a Knot of the old Wood to the Bottom of each, and bury them in the Ground, that the uppermoſt Eye may be even with the Surface of the Gound; if this be rightly obſerv'd, there will be no Danger of their ſucceeding.

Look over your Vines againſt the Walls, rubbing off all ſmall dangling Shoots, which are now beginning to puſh out; and at this Time a great Quantity of Vines may be look'd over in a very ſhort time, and much Labour ſav'd, which would be occaſion'd, were theſe Shoots permitted to remain on a Month longer.

Your Beds of Strawberries muſt now be carefully weeded; and if the Seaſon proves very dry, it will be proper to water them, otherwiſe they will produce but little Fruit.

Keep the Borders near your Fruit-trees clean from Weeds and large growing Plants, for theſe rob your Trees of their Nouriſhment. You ſhould alſo keep the Ground clean between your Rows of Vines in the Vineyard; and now the Stakes ſhould be fix'd to them, and the Branches faſten'd thereto; which is better than to let the Stakes remain to them all the Winter, becauſe they would decay more in the Winter than the Summer; and the Vines do not require to be ſtak'd in that Seaſon.

In the middle of this Month you muſt intirely uncover thoſe Fig-trees which were ſkreen'd from the Froſt in Winter; but this ſhould be done by Degrees; for the young Fruit will be in Danger, if they are ſuddenly expos'd to the open Air.

Your Fruits in the Forcing-frame muſt now have a large Share of freſh Air in proportion to the Heat of the Weather; and their Branches ſhould frequently be ſprinkled over with Water, which will be ſerviceable to the Trees, and cauſe the Fruit to be fairer; and if their Roots are now and then water'd, it will be very ſerviceable to them, eſpecially if they are on a dry Soil.

Fruits in prime, or yet laſting.

Pears; Franc-real, Bergamot Bugi, St. Martial, Lord Cheney's Winter Green, Beſſey de Chaumontelle, Carmelite; and for baking, the Cadillac, Parkinſon's Warden, and the *Engliſh* Warden.

Apples; Golden Ruſſet, Pile's Ruſſet, Wheeler's Ruſſet, John Apple, Stone Pippin, with ſome others.

In the Forcing-frame, Cherries, Maſculine Apricock, ſome Plums, and on the Hot-bed Strawberries.

Work to be done in the NURSERY.

The Beginning of this Month you may ſafely tranſplant moſt Sorts of Evergreens, as Hollies, Yews, Laurels, Alaternus's, Phillyrea, Box, Evergreen Oaks, Firs, Pines, Cedars, Junipers, *&c.* obſerving, if poſſible, to do it in a cloudy Day, or when there are Showers of Rain, becauſe the Sun and Wind are apt to dry the Fibres of their Roots, while they are above Ground, which is very injurious to them. You ſhould obſerve to water them well to ſettle the Earth to their Roots, and cover the Surface of the Ground with Mulch, to prevent the Sun and Wind from penetrating to the Roots of your Plants.

You may now ſow Evergreen Oak Acorns, and the Seeds of Firs, Pines, Cedars; as alſo Seeds of moſt Exotick Trees, which are brought from *Carolina*, *Virginia*, and moſt Northern Parts of *America*. The particular Directions for doing this are exhibited under their proper Articles.

The Beginning of this Month you may graft Hollies, and about the middle you may inarch Firs, Pines, Junipers, *&c.* by which Method you may propagate ſome of the ſcarce Sorts; but the Trees thus rais'd will never grow ſo large as thoſe rais'd from Seeds.

You ſhould now look over your Grafts, and obſerve, where the Loam is much crack'd, to renew it, leſt the drying Winds penetrate to the Grafts, and deſtroy them. And look over your Buds which are now ſhooting, and where you obſerve their Tops infeſted with Inſects, and their Leaves curl'd, you ſhould pull them off before the Inſects ſpread too far.

Keep your Ground clean between your Rows of Trees in the Nurſery, for if Weeds are permitted to grow this Month, they will ſoon over-top young Trees, and greatly weaken them; for there is nothing more prejudicial to Trees, than ſuffering the Weeds to grow amongſt them.

If this Month ſhould prove dry, you muſt diligently water your Seed-beds of Evergreens, Foreſt-trees, and Shrubs; as alſo the young Plantations which were drawn out of the Seed-bed; as alſo the Stocks for Fruit-trees, which have been lately planted; for theſe being ſmall, the Sun and Wind will ſoon penetrate to their Roots, and dry them up.

The Beds wherein you ſowed Seeds either in Autumn, or the laſt Month, ſhould now be carefully weeded; for the young Trees will many of them begin to appear, ſo that if the Weeds are permitted to grow, they will greatly endanger them. The Tubs or Pots of Cedars which are beginning to come up, muſt now be removed to a ſhady Situation; for too much Sun will ſoon deſtroy theſe young Plants.

Work to be done in the PLEASURE-GARDEN.

Your Gravel-Walks which were broken up and turn'd the laſt Month, ſhould now be rak'd level, and roll'd, that they may be ready for uſe; and your Graſs-Walks muſt now be duly mow'd; for this is a Seaſon when moſt People delight to walk out, ſo that the Walks of the Garden ought to be well kept.

Clean the Borders of your Pleaſure-Garden from Weeds, and tie up all your tall growing Plants to Sticks, to prevent their being broken or blown down by Wind.

You may now ſow ſuch annual Flowers in your Borders, as do not require any artificial Heat to bring them forward, as Candy-tuft, Venus Looking-glaſs, Lupines of ſeveral Sorts, Sweet Peaſe, Tangier Peaſe, Dwarf Lychnis, Lobel's Catchfly, Venus Navelwort, Convolvulus Minor, Naſturtium Indicum, Flos Adonis, Lavatera, Oriental Mallow, Carthamus or Baſtard Saffron, Hieraciums of ſeveral Sorts, Jacea's, with ſeveral other hardy Kinds of Annuals, which thrive better if ſown where they are to remain, than if they are tranſplanted; therefore they ſhould be ſown thin in Patches upon the Borders of the Pleaſure-Garden, and when they are come up, they ſhould be thinn'd, leaving but few Plants in each Patch to flower, that they may be the ſtronger.

In this Month you ſhould ſow moſt Sorts of hardy Perennial and Biennial Plants in your Flower Nurſery, which were not ſown the former Month, as Canterbury Bells, Columbines, Sweet Williams, Pinks, Carnations, Hollihock, French Honeyſuckles, Stock Gilliflowers, Wall Flowers, with many other Sorts, which are rais'd to ſupply the Borders of the Pleaſure-Garden.

The Beginning of this Month you may make ſome ſlender Hot-beds to ſow ſuch of the Annuals, as require a little Warmth to bring them forward; but will do better, if rais'd under Mats, than under Glaſſes, which draw them too much; and though they are ſomewhat later in this Management, yet there is no Inconvenience in that, becauſe they are deſign'd to come in Autumn, when there is a Scarcity of other Flowers, which renders them the more acceptable: Of theſe are the African, French Marygold, Convolvulus Major, Balſamines, Marvel of Peru, Sweet Sultan, Indian Pink, with ſome others.

You muſt now make freſh Hot-beds for tranſplanting your tender Annuals, as Amaranthus's, Amaranthoides's, Double-ſtrip'd Balſamines, *&c.* which muſt be brought forward at this Seaſon, otherwiſe they will not arrive to any Degree of Beauty, which chiefly conſiſts in their Strength.

Put ſome more Roots of Tuberoſes into a moderate Hot-bed to ſucceed thoſe which were planted the former Month, that there may be a Continuance of their Flowers through the Seaſon.

Your Tubs of Seedling Auricula's and Polyanthus's muſt be carefully ſkreen'd from the Sun; for if they are expos'd to its full Heat but one Day, it will deſtroy them while they are young; you muſt alſo frequently refreſh them with Water.

Set Sticks to your Carnations, which now begin to ſhoot their Spindles for flowering, and faſten them to prevent their being broken by the Wind.

Your fine Auricula's will now begin to ſhew their beautiful Flowers; therefore the Pots ſhould be remov'd under ſome Covert, to preſerve them from Wet, which would waſh the Mealineſs from off their Flowers, in which great Part of their Beauty conſiſts: They ſhould alſo be defended from the Heat of the Sun, which would haſten their Decay; but they muſt have as much free Air as poſſible, otherwiſe they will draw up very weak; and thoſe of them, from which you would ſave Seeds, ſhould be removed into the open Air as ſoon as they are fully blown, and placed where they may have the Morning Sun and a free Air, without which they will not produce good Seeds.

The Beds of fine Ranunculus's, Anemonies, Tulips and Hyacinths which are now in Flower, ſhould be covered either with Mats or Cloths, to defend them from Wet, and the Heat of the Sun, by which Method they may be preſerved a much longer Time in Beauty: but you muſt obſerve to open them every Morning and Evening, that they may enjoy as much free Air as poſſible, without which they will not do well.

Toward the latter End of this Month you may take up the Roots of Saffron, Colchicums, and ſuch other bulbous-rooted Flowers as blow at *Michaelmas*, whoſe Leaves are now decay'd, ſo that the ſooner they are taken up, they will be the better. Theſe may be kept out of the Ground until *July*, when they muſt be planted again.

You may now tranſplant moſt Sorts of Evergreens with great Safety, provided the Air is clouded, and there is a Proſpect of Rain in a ſhort Time; but if the Ground is very dry where they are to be planted, you ſhould open large Holes, where the Trees are to be placed, and pour a large Quantity of Water into each, ſo as to render the Ground like Pap, or Mud; then place the Trees therein, and after the Earth is filled in about the Roots, make it hollow like a Baſon to contain Water, and cover the Surface with Mulch, to prevent the Sun and Air from penetrating the Ground to dry their Roots, and repeat watering the Trees twice a Week, provided the Weather ſhould prove dry.

Where Phillyrea's, Alaternus's, Laurels, or other hardy Evergreen-trees are grown rude, they may now be reduced to the Figure you intend, by cutting their Branches in cloſe to the Stems, and when they ſhoot, they may be train'd to the Order they are deſired.

Plants now in Flower in the Pleaſure-Garden.

Anemonies, Ranunculus's of various Kinds, Polyanthus's, Auricula's, Tulips, Crown Imperials, Hepatica's, Hyacinths of various Sorts, Narciſſus's, Daffodils, Jonquils, Violets, Muſcaria's, Dwarff-flag Iris, Great Snow-Drop, Spring Cyclamens, Spring Colchicums, Pulſatilla's, Bulbous Fumitary, Double Ladies Smock, Linaria's, Double Pilewort, Starry Hyacinths, Dents Canis, Double Daizies, Fritillaria's of various Kinds, Gentianella, Double Caltha Paluſtris, Columbines, large Green-flower'd Ornithogalum, Perſian Lily, Double Saxifrage, Venetian Vetch, Lychnis's, Alyſſon Creticum, Borrage-leav'd Verbaſcum, Blue-flower'd Perennial Moth-Mullain, with ſome others.

Hardy Trees and Shrubs now in Flower.

Lilac, with white, purple, and blue Flowers, Perſian Lilac with Privet-leaves, commonly called the Perſian Jaſmine, Perſian Lilac with cut Leaves, Laburnums, Double-flowering Pear-tree, Cherry Plum, Almond with white and peach-colour'd Bloſſoms, Amelanchier, Aria Theophraſti, Viburnum, Bird Cherry, Corniſh Cherry, Arbor Judæ, Double-flowering Cherry, Cockſpur-Hawthorn, Dwarf-Almond with ſingle and double Flowers, Hypericum Frutex, Early white and Italian Honeyſuckles, Yellow Jaſmine, Lauruſtinus, Scorpion Senna, with ſome others.

Work to be done in the Green-houſe and Stove.

Your Bays, Lauruſtinus's, Myrtles, and other hardy Plants muſt now be taken out of the Green-houſe, that the Orange-trees, and other leſs hardy Plants, may be placed thinner, that they may have a greater Share of Air; but thoſe Plants which are taken out, ſhould be placed where they may be defended from cold Winds, otherwiſe they will ſuffer, being made ſomewhat tender by ſtanding in the Houſe.

Such of your Orange-trees or other Exotick Plants as want ſhifting, ſhould now be removed, and thoſe which require larger Pots or Tubs, muſt be placed therein, obſerving, when you take them out of the Tubs or Pots, to pare off all mouldy or decay'd Roots, and waſh their Stems and Heads, to cleanſe them from the Filth they have contracted by remaining in the Houſe; and when they are new planted, they ſhould be duly watered, and ſhaded in the Heat of the Day from the Violence of the Sun. By removing them early in this Month, they will have Time to make new Roots before they are ſet abroad, and will have Strength to produce their Flowers in Plenty.

Thoſe Trees which are not removed this Seaſon, ſhould have the Earth taken out of the Top and Sides of the Tubs or Pots, and fill'd up again with freſh rich Earth, and their Stems and Heads cleaned as before, this will ſtrengthen them greatly for flowering; but you ſhould never apply any hot Kinds of Dung to the Surface of the Earth, as is by ſome unſkilfully done, to the Deſtruction of their Trees: If therefore you would lay any Dung upon the Surface of the Earth, it ſhould be rotten neats Dung; but this ſhould not be done in too great Quantities.

Open the Windows of your Green-Houſe moſt part of the Day, when the Air is mild; for at this Seaſon the Plants require a large Share of freſh Air, otherwiſe they will draw up weak, and produce but few Flowers, and will be leſs able to bear the open Air, when they are removed out of the Houſe.

You may now graft Oranges, Jaſmines, and other tender Plants by approach; but ſuch as will take Buds, are better if propagated that way; for Trees inarch'd ſeldom unite ſo well with the Graft, and rarely grow to ſo large a Subſtance.

The Bark-beds in the Stoves, which have declined their Heat, and were not renewed the former Month, ſhould now be ſtirred up with a Fork almoſt to the Bottom, and ſome freſh Bark added thereto, which will renew their Heat; at the ſame Time you ſhould ſhift ſuch of your Plants as require it, into larger Pots, giving them freſh Earth, and then plunge them down into the Bark again immediately; but this muſt be done when the Air is warm, becauſe there will be a neceſſity to open the Glaſſes pretty often, and if the Air be ſharp, it will injure the Plants.

Your Anana's or Pine-Apples muſt now be carefully tended, obſerving to refreſh them often with Water, as alſo to preſerve a kindly Heat in the Beds, and cover the Glaſſes every Night to keep them warm; but when the Sun is very hot, they ſhould have Air admitted by raiſing the Glaſſes a little, otherwiſe they will be in Danger of Scorching.

Shift ſuch of your ſeedling Exotick Plants as require it, into larger Pots, and ſtir up the Bark of the Beds to renew their Heat, and then plunge the Pots down again, obſerving to water and ſhade them until they have taken Root.

The Coffee-trees will now begin to ſhew their Flower-buds; therefore you ſhould keep their Leaves and Stems free from Filth by waſhing it off, whenever it appears; and refreſh the Trees often with Water, which will cauſe them to flower ſtrong.

Plants now in Flower in the GREEN-HOUSE *and* STOVE.

Geraniums of ſeveral Sorts, Ilex-leav'd Jaſmine, Candy Tuft-tree, African Aſphodel with Onion-leaves, ditto with Aloe-leaves, Tree Scabious, Ciſtus's, Anemonoſpermos's, Ficoides's of ſeveral Sorts, Aloes of ſeveral Kinds, Coronilla argentea Cretica, Cytiſſus Canarienſis, Medicago fruteſcens, Aleppo Ceclamens, Hermannia's two Sorts, Colutea Æthiopica, Polygala Africana, Myrto-ciſtus, African Shrubby Tanſy, Three-leav'd African Sumach, Melianthus Minor fœtidus, Cotyledons, Turnera, Malpighia, Humble-plant, Ciſtus Halimi folio, with ſome others.

AQUIFOLIUM *ſeu* AGRIFOLIUM; [of 'Ακὶς, a Prickle, and *folium*, *Lat.* a Leaf; ſo call'd, becauſe the Leaves are arm'd with many Prickles.] The Holly-Tree.

The *Characters* are;

The Leaves are ſet about the Edges with long ſharp ſtiff Prickles; the Berries are ſmall, round, and for the moſt Part of a red Colour, containing four Triangular ſtriated Seeds in each.

The *Species* are;

1. AQUIFOLIUM *baccis rubris. H. L.* The Common Holly, with red Berries.
2. AQUIFOLIUM *baccis luteis. H. L.* Yellow berried Holly.
3. AQUIFOLIUM *baccis albis.* White berried Holly.
4. AQUIFOLIUM *foliis ex luteo variegatis. H. R. Par. Aquifolium aureum. Munt. H.* 163. Yellow blotch'd Holly.
5. AQUIFOLIUM *foliis ex albo variegatis. H. L.* White blotch'd Holly.
6. AQUIFOLIUM *echinatâ folii Superficie. Corn.* 180. Hedge-hog Holly.
7. AQUIFOLIUM *echinatâ folii Superficie, foliis ex luteo variegatis.* Yellow blotch'd Hedge-hog Holly.
8. AQUIFOLIUM *echinatâ folii Superficie, limbis aureis.* Gold-edged Hedge-hog Holly.
9. AQUIFOLIUM *echinatâ folii Superficie, limbis argenteis.* Silver-edg'd Hedge-hog Holly.
10. AQUIFOLIUM *foliis longioribus, limbis & ſpinis ex unico tantum latere per totum argenteo pictis. Pluk. Alm.* 38. *Broderick*'s Holly; *vulgo.*
11. AQUIFOLIUM *foliis ſubrotundis, limbis & ſpinis utrinque argentatis, Aquifolium elegans. D. Doct. Eales. Pluk. Alm.* 38. *Eales*'s Holly; *vulgo.*

31. AQUIFOLIUM *foliis parvis, interdum vix ſpinoſis.* Box-leav'd Holly; *vulgo.*
32. AQUIFOLIUM *foliis parvis, interdum vix ſpinoſis, limbis foliorum argentatis. Whitmill*'s Holly; *vulgo.*
33. AQUIFOLIUM *Carolinianum, anguſtifolium, ſpinis raris breviſſimis. Carolina* Holly, with ſmooth Leaves; *vulgo.*

This Tree, tho' wild in many Parts of *England*, deſerves a Place in large Gardens, as being very ornamental to the Wilderneſs and ever-green Garden; but eſpecially when we take in the large Variety of beautiful variegated Sorts, of which we have a much greater Number than is to be found in any Part of *Europe*: Theſe are all diſtinguiſh'd by the different Names of the Perſons who firſt obſerv'd them, or from the Places where they grew.

I have ſeen in one Garden, *viz.* Mr. *Chriſtopher Gray*'s, near *Fulham*, above thirty different Varieties, which are either ſtrip'd or blotch'd, with White, Yellow, or Copper Colour.

Theſe Trees were formerly in much greater Requeſt than at preſent, and there was ſcarcely a ſmall Garden of any Worth, but was fill'd with theſe Trees, which were clipp'd either into Pyramids, Balls, or ſome other Figures; but as this was crowding a Garden too much with one Sort of Plant, and the Faſhion of clipp'd Greens going off, ſo now they are almoſt wholly neglected: Such are the Changes in Mens Tempers and Fancies, that what is one Year eſteem'd, is the next deſpis'd.

I would not here be thought to be an Advocate for clipp'd Trees; no, I am infinitely more delighted with a Tree in all its Luxuriancy of Branches, waving about with every Guſt of Wind; but yet I think there is a great Beauty in theſe Trees, if rightly diſpos'd in a Garden, but more eſpecially in ſuch as are of a large Extent, by being intermix'd with other Sorts of Ever-greens, to form regular Clumps, or plac'd in Quarters of Ever-greens, or to form Columns at the Entrances of Wilderneſs Quarters, or to plant in Niches of Ever-green Hedges; in all which Places they have an agreeable Effect.

All the variegated Sorts are propagated by budding or grafting them on the *Plain Holly* Stocks; the beſt Time for budding them, is in *July*, and for graſting them, in *March*.

The Manner of raiſing the common *Hollies*, is by ſowing the Berries, which, if ſown as ſoon as ripe, will lie two Years in the Ground; you may therefore mix the Berries with dry Sand, and put them in a large Garden Pot, burying it in the Ground till the next *Auguſt* or *September*; and take them out and ſow them on a Bed of common Earth, covering the Seeds about a quarter of an Inch with light Mould, and the Spring following the Plants will appear above Ground: But as this is a tedious Method, and the young Plants making but ſmall Progreſs for the two or three firſt Years, ſo I would rather adviſe the purchaſing of young Stocks, of about three or four Years Growth, of ſome Nurſery Men, who raiſe them for Sale, and theſe will be fit to bud or graft the ſecond Year after they are planted; or you may purchaſe young Plants, of the ſeveral Kinds, as have been budded or grafted two Years, which are generally ſold very reaſonably in the Nurſeries, than to hazard the Budding them yourſelf, eſpecially if you are not ſure of being provided with Cuttings very near you.

Hollies are alſo planted for Hedges, and have been by ſome very much eſteem'd for that Purpoſe; but the Leaves being very large, when theſe Hedges are clipp'd, they are generally cut in Pieces, and appear very ragged, otherwiſe they make a very durable ſtrong Hedge, and very proper for an outſide Fence of a Green Garden.

The beſt time for tranſplanting this Tree is in *April*, in moiſt Weather; and if the Seaſon is good, and they are carefully remov'd, there will be little Danger of their growing; they may alſo be tranſplanted in *Auguſt*, if the Seaſon proves moiſt, and they will put out new Roots before Winter; but if you do it at this Seaſon, you muſt be careful to mulch the Ground about the Roots, to keep the Froſt from reaching them in Winter, which would be apt to deſtroy your new-planted Trees.

If the Trees are large you intend to remove, and have been growing ſome time in the Places where they ſtand, you ſhould dig about them, and cut their Roots the Year before, that they may produce young Fibres, to keep the Earth from falling away from the Roots; and if you remove them to any Diſtance, it will be adviſeable to put them into Baſkets; and when you plant them, you may either cut off the Sides of the Baſket, or if they are but looſely made, ſuffer them to remain intire, for they will ſoon rot in the Ground.

You muſt alſo be very careful to ſupply your new-planted *Hollies* with Water, for the two firſt Years, if the Seaſons prove dry; after this Time there will be little Danger of their miſcarrying.

AQUILEGIA; [is called alſo *Aquilina*, of *Aquila*, L. an Eagle, becauſe the Flower reſembles an Eagle: *Fabius Columna* ſays, it is the *Iſopynus of Dioſcorides*, and demonſtrates it to be ſo call'd, becauſe the little Sheaths riſe after that Manner.] Columbine.

The *Characters* are;

It hath Leaves like the Meadow Rue; the Flowers are pendulous, and of an anomalous Figure; the Piſtil of the Flower becomes a membraneous Fruit, conſiſting of many Huſks or Pods; each of which contains many ſhining black Seeds.

The *Species* are;

1. AQUILEGIA *ſylveſtris. C. B.* The Common wild Columbine.

2. AQUILEGIA *ſtellata, flore violaceo. Hort. Eyſt.* The ſtarry Columbine, with violet-colour'd Flowers.

3. AQUILEGIA *hortenſis ſimplex. C. B.* The ſingle Garden Columbine.

4. AQUILEGIA *montana magno flore. C. B.* Mountain Columbine, with large Flowers.

5. AQUILEGIA *Canadenſis, præcox, procerior. H. R. Par.* Early-flowering *Canada* Columbine.

6. AQUILEGIA *pumila præcox, Canadenſis. Cornut.* Dwarf early-flowering *Canada* Columbine.

7. AQUILEGIA *hortenſis, multiplex, flore magno cæruleo, C. B.* Double Garden Columbine, with large blue Flowers.

8. AQUILEGIA *flore variegato duplici. Suvert.* Double variegated Columbine.

9. AQUILEGIA *flore roſeo multiplici. C. B. P.* 145. The Roſe Columbine.

There are great Varieties of this Plant, which are preſerv'd in curious Gardens; the Flowers of which are very double, and beautifully variegated with Blue, Purple, Red, and White. Theſe are very ornamental Plants in Borders of large Gardens, producing their beautiful Flowers in *May* and *June*; and are very proper to mix with other Flowers, for Pots to adorn Chimnies or Halls, at that Seaſon.

They are all rais'd by ſowing the Seeds, or parting the old Roots, but the former Method is chiefly practis'd; for the old Roots are very apt to degenerate after they have blown two Years, and become quite plain.

The Seeds ſhould be ſown in a nurſery Bed in *Auguſt* or *September*; for the Seeds kept till Spring do ſeldom grow well; in the *March* following your young Plants will appear above Ground; you muſt therefore clear them from Weeds, and if the Seaſon ſhould be dry, refreſh them with Water, that they may gather Strength.

In the Beginning of *May* theſe Plants will be ſtrong enough to tranſplant; you muſt therefore prepare ſome Beds of good freſh undung'd Earth, planting them therein at eight or nine Inches Diſtance every way, keeping them clear from Weeds, and refreſhing them with a little Water, as they may require it.

At *Michaelmas* you may remove them into the Borders of your Flower Garden, and the *May* following they will produce Flowers; but if you intend to maintain their Roots, you ſhould not ſuffer them to ſeed, but crop off all their Flower-Stems ſo ſoon as the Flowers are paſt.

But in order to be ſure of having no ſingle or bad Flowers in your Borders, you may ſuffer them to remain in the nurſery Beds until they have blown, at which time you may ſtick a Stake by each Root you fancy to preſerve, and pull out all the ſingle or bad colour'd ones, and throw them away, cutting off all the Flowers from your beſt Roots ſo ſoon as they have ſhewn themſelves, which will greatly add to the preſerving them fair in their Colours; and theſe Roots will be ſtrong enough to divide at *Michaelmas*, when you may tranſplant them into your Borders, but do not divide them too ſmall, which will weaken their Bloom the ſucceeding Year.

In order to keep up a Succeſſion of good Flowers, you ſhould ſow freſh Seeds every Year; and if you can meet with a Friend, at ſome Diſtance, who is furniſh'd with good Flowers of this Kind, it will be very advantageous to both Parties, to exchange Seeds once in two Years, by which Means they will not be apt to degenerate into plain Colours.

ARALIA, Berry-bearing *Angelica.*

The *Characters* are;

The Flower conſiſts of many Leaves, which expand in Form of a Roſe, which are naked, growing on the Top of the Ovary: Theſe Flowers are ſucceeded by globular Fruit, which are ſoft and ſucculent, and are full of oblong Seeds.

The *Species* are;

1. ARALIA *Canadenſis. Tourn.* *Canada* Berry-bearing Angelica.

2. ARALIA *caule aphyllo, radice repente. D. Sarrazin. Tourn.* Berry-bearing Angelica, with a naked Stalk and a creeping Root.

3. ARALIA *arboreſcens, ſpinoſa. Vaill.* Angelica-Tree: *vulgo.*

The two firſt *Species* die to the Surface every Year, and riſe again the ſucceeding Spring, and in *July* and *Auguſt* produce their Flowers; and, if the Seaſon is warm, do perfect their Fruit in *September*.

Theſe are propagated either by ſowing their Seeds, or by parting of their Roots; which laſt being the moſt expeditious Method, is commonly practiſ'd in *England*; for the Seeds often abide in the Ground until the ſecond Year before they ariſe, and are two Years more before they flower.

They love a good freſh Soil, not too wet, and ſhould be planted early in the Spring, and are very hardy in reſpect to Cold.

The third Sort grows with us to the Height of ſeven or eight Feet: It has produc'd Flowers in the *Phyſick-Garden* at *Chelſea* two or three times, but has not perfected its Seeds in *England* that I have yet heard.

This Shrub requires a dry Soil, and a warm Situation, otherwiſe it is ſubject to be injur'd by Froſts in the Winter: This is only propagated by Seeds, which are frequently brought from *America*.

ARBOR, a Tree; is defin'd to be a woody Plant, the biggeſt of all in Thickneſs and Height, whoſe Stock is perennial and ſingle by Nature, which is divided into many larger Branches, which the *Greeks* call 'Αρκέμονας and ὄζȣς, and afterwards into many ſmall Branches, [Sprigs] which the *Greeks* call κλάδȣς, and the *Latins Surculos*.

ARBOR CAMPHORIFERA. *Vide* Camphorifera.

ARBOR CORAL. *Vide* Corallodendron.

ARBOR JUDÆ. *Vide* Siliquaſtrum.

ARBOR VIRGINIANA, *Citriæ vel Limoniæ folio, Benzoinum fundens. H. A.* The Benjamin-Tree: *vulgo*.

This Tree is found in great Plenty in moſt Parts of *Virginia* and *Carolina*, from whence it is brought to *England*, and was for ſeveral Years preſerv'd in Pots, and hous'd in Winter, but hath been ſince found to be hardy enough to reſiſt the ſevereſt Cold of our Winters in the open Ground.

This Plant may be propagated by laying down the young Branches in the Spring of the Year, which, if they are ſupply'd with Water in a dry Seaſon, will be rooted enough by the next Spring to tranſplant.

Theſe Trees produce ſmall yellowiſh Flowers out of the young Wood, at two Seaſons, *viz.* in *March* and *October*, but I never ſaw any Fruit ſucceed them. This Tree is kept in curious Gardens of Trees amongſt many other of the ſame Country, but I don't know any extraordinary Beauty or Uſe that belongs to it: Indeed, when it was firſt introduc'd, it was generally believ'd, that the Gum *Benjamin* of the Shops was an Exudation from this Tree, but it is now thought to proceed from a very different Tree.

An. **ARBOR** *Zeylanica, Cotini foliis, ſubtus lanugine villoſis, floribus albis, cuculi modo laciniatis. Pluk. Phyt.* The Snowdrop Tree: *vulgo*.

This Tree is very hardy in reſpect to Cold, ſtanding abroad in the open Air, without ſuffering from our ſevereſt Froſts, but is difficult to increaſe, the Layers being commonly two Years before they ſtrike Root, nor will they root at all, unleſs the Branches are very young, and they are ſlit at a Joint, as is practiſ'd in laying of Carnations. When theſe Layers are rooted, they may be tranſplanted into ſmall Quarters of flowering Shrubs, where, among thoſe of a middling Growth, this Tree will add to the Variety.

ARBOREOUS, [*Arboreus*, *Lat.* of or belonging to, or of the Nature of Trees.] An Epithet which Botaniſts apply to thoſe *Fungus's* or *Moſſes* which grow on Trees, in Diſtinction from thoſe that grow on the Ground, as *Agaric*, *Jews-Ear*, &c.

ARBOURS, [*Arboreta*, of *Arbor*, *Lat.*] Theſe were formerly in greater Eſteem with us than at preſent; few Gardens were without cover'd Arbours and ſhady Seats; but of late they have been much rejected, and that not without good Reaſon; for beſides the great Expence in their firſt erecting, they were a continual Charge in keeping them repair'd; for the Wet ſoaking thro' the Leaves of the Trees to the Woodwork, was, by the continual Shade, and for want of free Air, detain'd ſo long as to rot the Wood (which if wholly expos'd to the Weather, would have laſted ſeven or eight Years) in two or three; beſide, the Seats are continually damp, and unhealthy; for which Reaſon, cover'd Seats or Alcoves are every where at this Time preferr'd to them.

Arbours are generally made of Lattice-work, either in Wood or Iron, and cover'd with *Elms*, *Limes*, *Horn-beam*, or with *Creepers*, as *Honey-ſuckles*, *Jaſmines*, or *Paſſion-flowers*, either of which will anſwer the Purpoſe very well, if rightly manag'd.

ARBUTUS. The Strawberry-Tree.

The *Characters* are;

It is ever-green; the Leaves are roundiſh, and ſerrated on the Edges; the Flowers conſiſt of one Leaf, and are ſhap'd like a Pitcher; the Fruit is of a fleſhy Subſtance, and, in its outward Appearance, very like a Strawberry, but is divided into five Cells, in which are contain'd many ſmall Seeds.

The *Species* are;

1. ARBUTUS *folio ſerrato. C. B.* The common Strawberry-Tree.
2. ARBUTUS *folio ſerrato, flore oblongo, fructu ovato. Michel. Hort. Piſ.* Strawberry-Tree, with longer Flowers and Egg-ſhap'd Fruit.
3. ARBUTUS *folio ſerrato, flore duplici.* Strawberry-Tree, with double Flowers.

This Tree has its Name from the Reſemblance the Fruit bears to that of a *Strawberry*, but it is of an auſtere ſour Taſte; tho' I have been inform'd, that in *Ireland*, where this Tree abounds, the Fruit is ſold, and eaten. In *England* they are chiefly brought to the Markets with ſmall Branches of the Tree, having ſmall Bunches of Flowers upon them, and made up into Noſegays with other Flowers, and ſome Sprigs of the *Amomum Plinii*, or *Winter Cherry*, which at that Seaſon is very acceptable, when there are few Flowers to be had.

The Time of this Fruit being ripe, is in *November*, at which Seaſon the Flowers are blown for the next Year's Fruit; ſo that from the Time of flowering to the ripening of the Fruit, is one whole Year.

The beſt Method of propagating theſe Trees is, by ſowing their Seeds, which ſhould be preſerv'd in dry Sand till *March*; at which Time you ſhould ſow them upon a very moderate Hot-bed (which greatly promotes its Vegetation) covering it about a quarter of an Inch with light Earth, and ſcreening it from Froſts or great Rains: Toward the Middle or latter End of *March* your young Plants will begin to appear; you muſt therefore keep them clear from Weeds, and give them frequent Waterings, as the Seaſon may require; and if your Plants have done well, they will be, by *Autumn*, about five or ſix Inches high: But as theſe Trees are ſubject to receive Damage from Froſts, eſpecially while they are young, therefore you muſt hoop the Bed over, that when bad Weather comes, you may cover it with Mats and Straw to keep out the Froſt.

The Beginning of *April* following, you may tranſplant theſe Trees, each into a ſmall Pot; but in doing of this, be very careful to take them up with as much Earth to their Roots as poſſible, for they are bad rooting Plants, and very ſubject to miſcarry on being remov'd; and 'tis for this Reaſon that I adviſe their being put into ſmall Pots; for when they have fill'd the Pot with Roots, they may be turn'd out into large Pots, or the open Ground, without any Hazard of their dying.

When you have put your young Plants into the ſmall Pots, you ſhould plunge them into another very moderate Hot-bed, to encourage their taking new Root, ſhading them from the Sun in the middle of the Day, and giving them Water as they may require: In this Bed it will be proper to let the Pots remain moſt part of the Summer; for if the Pots are taken out, and ſet upon the Ground, the Smallneſs of their Size will occaſion the Earth in them to dry ſo faſt, that watering will ſcarcely preſerve your Trees alive; but if they are kept growing all the Summer, they will be near a Foot high by the next Autumn; but it will be adviſeable to ſcreen them from the Froſt during their Continuance in Pots, by plunging them into the Ground in a warm Place, and covering them with Mats in bad Weather.

When your Trees are grown to be three or four Foot high, you may ſhake them out of the Pots into the open Ground in the Places where they are to remain; but this ſhould be done in *April*, that they may have taken good Root before the Winter, which would be apt to manage them if newly planted.

Theſe Trees are tolerably hardy, and are ſeldom hurt, except in extreme hard Winters, which many times kills the young and tender Branches, but rarely deſtroys the whole Trees; therefore however dead your Trees may appear after a hard Winter, yet I would adviſe you to let them remain till the ſucceeding Summer has ſufficiently demonſtrated what are living, and what are dead; for the Winter *Anno* 1728-9, gave us great Reaſon to believe moſt of the Trees of this Kind were deſtroy'd, and many People were ſo haſty, as to dig up, or cut down many of their Trees; whereas all thoſe People who had Patience to let their Trees remain, found, that ſcarce one in five hundred fail'd to come out again the next Summer, and made handſome Plants that Seaſon.

ARCUATION; [of *Arcus* a Bow; of *Arcuo*, *Lat.* to bend or bow like an Arch.] The Raiſing of Trees by Layers.

The firſt Thing that is to be done, is, to procure large ſtrong Mother Plants, which are uſually call'd *Stools*. It is no matter whether the Trees be crooked, or otherwiſe deform'd; and the larger they are, the better they are to be cut down cloſe to the Ground. They are to be planted in a Border ſix Feet wide, and in a ſtrait Line ſix Feet aſunder.

The Border muſt be well trench'd, or dug clear from all *Roots*, *Clods*, *Stones*, or any other Obſtructions. Theſe Trunks or Stools being planted in this Trench, will throw out twenty, thirty, forty, or fifty Plants, which may be begun to be laid about the *Michaelmas* following; at which Time, if the Stools have been carefully manag'd, they will have ſhot five, ſix, or more main Branches out of the Root, and on every one of theſe, as many Side or Collateral Branches.

Theſe main Branches muſt be bent down to the Ground; and ſome cut them half through, that they may bend the eaſier.

When the main Branches are thus laid round the Stool, and pegg'd faſt down, then the ſmall ones may be pegg'd down too, if you pleaſe; and thus the *main Branches* or *Shoots* will be cover'd all over, except the very Top, and all the *ſmall* and *ſide Branches* muſt be cover'd two or three Inches thick upon the Joints: Some Perſons give the Branches a Twiſt, in order to make them take Root the ſooner. If they be mulch'd, or ſome ſtrawy Dung be laid over them, it will be of Uſe to keep them moiſt: They ought alſo to have a large Baſon of Earth made round them to hold the Water, in order to water them the enſuing Summer, which they will require at leaſt two or three times a Week, if the Weather be hot and dry.

About the Middle of *September* following, they may be open'd and examin'd, to ſee if they have taken Root or not, which it is very probable they will have done; but if not, they muſt be let alone to lie till the next Spring, and then they are to be taken up and planted in the Nurſery.

This may be done to the *Dutch*, *Witch* and *Engliſh Elm*, the *Abeal*, *Lime*, *Alder*, *Platanus*, and all Sorts of *Sallows* and *Willows*.

AREA, is the internal Capacity, or Content of any given Boundary or Limits, of what Figure or Shape ſoever it be.

ARGEMONE [of Ἄργεμα, becauſe it purges away the Miſtineſs of the Eyes: It is call'd the *Infernal Fig*, becauſe the *Capſule* pretty much reſembles a Fig; and *Infernal*, from its Aſperity.] Prickly Poppy.

The *Characters* are;

It hath an annual Root: The Leaves are laciniated, or jagged; which are terminated with Spines: The Flower conſiſts of many Leaves, which expand in Form of a Roſe: The Pointal of the Flower becomes a large trigonical Veſſel, which is divided into three Cells, wherein are contain'd many globular black Seeds.

There is but one *Species* of this Plant known, which is;

ARGEMONE *Mexicana*. *Tourn.* The Prickly Poppy.

This is an annual Plant, which is very common in moſt Parts of the *Weſt-Indies*, and is by the *Spaniards* call'd *Fico del Inferno*, or the *Devil's Fig*; there is no great Beauty nor Uſe of this Plant amongſt us, that I know of; but whoever hath a mind to cultivate it, ſhould, at firſt, ſow it on a Hot-bed, and in *June* tranſplant it out into the natural Borders, where, when once it has ſhed its Seed, there will not want a Supply of Plants for ſeveral Years after. I have been informed that Gumbouge is made from the Juice of this Plant.

ARGIL; [*Argilla*, *Lat.* a Sort of white Earth like Chalk, but more brittle.] Potters Clay.

ARA THEOPHRASTI; *vide* Cratægus.

ARISARUM. The Herb Friers Cowl.

The *Characters* are;

It agrees with the Dragon *and* Arum, *from both which this Plant differs, in having a Flower reſembling a Cowl.*

The *Species* are;

1. ARISARUM *latifolium, majus.* *C. B. P.* 196. Broad-leav'd Friers Cowl.

2. ARISARUM *anguſtifolium, Dioſcoridis, forte.* *C. B. P.* Narrow-leav'd Friers Cowl.

There are ſome other *Species* of this Plant, but thoſe two here-mention'd, are what I have obſerved in the *Engliſh* Gardens. They are both propagated by Off-ſets, which they ſend forth in Plenty; theſe ſhould be taken off from the old Roots, about the middle of *September*, which is the proper Seaſon for tranſplanting of them, their Leaves being at that Time almoſt decayed. Theſe Plants never riſe very high, ſo ſhould be placed amongſt others of low Growth, otherwiſe they may be overborn by their neighbouring Plants and deſtroyed. They ſhould have a freſh undunged Soil, and a Situation not too much expoſed to the Sun. They flower in *May*, but rarely produce any Seeds in our Climate.

ARISTA, of Corn, is that ſharp-pointed Needle that ſtands out from the Huſk or Hoſe of the Grain; the Beard or Awn of Corn, which the *French* call, *La Barbe du Blé*.

ARISTOLOCHIA; ['Αριϛολοχία, of ἄριϛος, beſt, and λοχεῖα, Purgations, which come forth after the Birth; as tho' it was the beſt Herb to expel the After-birth.] Birthwort.

The *Characters* are;

The Stalks are flexible; the Leaves are plac'd alternately on the Branches; the Flowers conſiſt of one Leaf, and are of an anomalous Figure, hollow'd like a Pipe, and ſhap'd like a Tongue, generally hooked: The Flower-cup turns to a membraneous, and, for the moſt part, oval-ſhap'd Fruit, which is divided into five Cells, and full of flat Seeds.

The *Species* are;

1. ARISTOLOCHIA *flore ex purpurâ nigro.* *C. B. P.* The round-rooted Birthwort.

2. ARISTOLOCHIA *longa vera.* *C. B. P.* True long-rooted Birthwort.

3. ARISTOLOCHIA *clematitis recta.* *C. B. P.* The climbing Birthwort.

4. ARISTOLOCHIA *Piſtolochia dicta.* *C. B. P.* *Spaniſh* Birthwort.

5. ARISTOLOCHIA *Piſtolochia dicta, Cretica, folio ſmilacis ſemper-virens.* *H. L.* The ever-green Birthwort from *Crete*.

6. ARISTOLOCHIA *polyrrhizos, auriculatis foliis, Virginiana.* *Pluk. Phyt.* *Virginian* Snake-root.

7. ARISTOLOCHIA *erecta, flore atro-purpureo, foliis anguſtis, radice repente.* *Plum. Cat.* Narrow-leav'd upright Birthwort with creeping Roots, commonly called *Contrayerva* in *Jamaica*.

8. ARISTOLOCHIA *folio cordiformi, flore longiſſimo auro-purpureo, radice repente.* *Plum. Cat.* Creeping rooted Birthwort, with long yellowiſh purple Flowers, and a heart-ſhap'd Leaf.

9. ARISTOLOCHIA *ſcandens, foliis laurinis, fructu maximo.* Climbing Birthwort with laurel Leaves, and the largeſt Fruit.

The firſt and ſecond Sorts are uſed in Medicine; but as they are very rare in *England*, their Roots are brought from the Southern Parts of *France*, (where they are very common) and are ſold in the Shops. Theſe Plants are both tolerably hardy, and will endure the Cold of our ordinary Winters very well, in the full Ground. Theſe Roots ſhould be planted early in the Spring, before they begin to ſhoot, in a warm Situation, and ſhould have a freſh light Soil, rather dry than moiſt. They ſhould be planted ſix Inches deep in the Earth, that they may be leſs expoſed to the Froſt, and in Summer the Drought will not ſo ſoon affect them. They will ſhoot up about two Feet high, and produce their Flowers in *June*, and in a kindly Seaſon they will perfect their Seeds in this Country. It will be very proper to have ſome Roots of each Sort in Pots, which may be ſhelter'd under a Frame in very ſevere Froſt, ſo that the Kinds may be preſerved, if thoſe in the full Ground ſhould be deſtroyed.

The third Sort is ſometimes uſed in Medicine. This is a terrible Plant for creeping at the Root, ſo that if once it has taken in a Garden, it will be difficult to extirpate again, and will deſtroy whatever Plants grow near it; therefore it ſhould be planted in ſome abject Part of the Garden by itſelf; for it will thrive in almoſt any Soil or Situation.

The fourth and fifth Sorts do grow wild in *Spain*, *Italy*, and the South of *France*; but in *England* they are preſerved for

Variety in Botanick Gardens. Theſe muſt be planted in Pots filled with light rich Earth, and ſhelter'd from ſevere Cold in Winter; otherwiſe they will be deſtroyed thereby; but they ſhould have as much free Air as poſſible in mild Weather. Theſe produce Flowers every Year; but never perfect their Seeds in this Country.

The ſixth Sort is the *Snakeroot*, which is greatly uſed in Medicine; but theſe Roots are brought over from *Virginia* and *Carolina*, where there are two or three *Species* of this Plant. In *England*, it is preſerved as a Curioſity, in Pots filled with light freſh Earth, and requires to be ſhelter'd from ſevere Cold in Winter; in Summer they muſt be frequently watered, and ſhould be placed in a well ſhelter'd Situation, where, in a good Seaſon, they will perfect their Seeds, by which new Plants may be obtain'd. Theſe Seeds ſhould be ſown on a Hot-bed early in the Spring, and when the Plants are come up, they muſt be tranſplanted into Pots, and managed as hath been directed for the old Plants.

The ſeventh, eighth, and ninth Sorts, are Natives of the warmeſt Parts of *America*, ſo muſt be preſerved with great Care in this Climate. Theſe may be propagated by ſowing their Seeds in the Spring; the beſt Method to raiſe them, is, to ſow the Seeds in Pots filled with light freſh Earth, and plunge them into a Hot-bed of Tanners-bark, obſerving to refreſh the Earth frequently with Water, as alſo to raiſe the Glaſſes, when the Sun is very hot, to let the Steam of the Bed paſs off; in about a Month or five Weeks after the Seeds are ſown, the Plants will begin to appear; when they ſhould be gently refreſhed with Water every other Day, and a proper Share of Air admitted to them, when the Weather is warm. When the Plants are advanced to be about two Inches high, they ſhould be carefully tranſplanted, each into a ſeparate Pot filled with freſh light Earth, and ſhould then be plunged into the Hot-bed again, obſerving to water and ſhade them until they have taken Root; after which Time they ſhould have Air admitted to them every Day in proportion to the Warmth of the Seaſon, and they muſt be frequently watered.

About the Beginning of *Auguſt* theſe Plants will have filled the Pots with their Roots, when they ſhould be ſhaken carefully out of the Pots, and their Roots trimmed; then they ſhould be planted into larger Pots filled with the ſame freſh Earth as before; and thoſe which are of low Growth ſhould be plunged into the Hot-bed again, but the taller Sorts ſhould be plunged into the Bark-ſtove, eſpecially the ninth Sort, which will riſe to a great Height.

The ſeventh Sort is known in *Jamaica* by the Name of *Contrayerva*, and is greatly uſed as an *Alexipharmic*, by the Inhabitants of that Iſland.

All theſe three Sorts will require to be kept in the Bark-ſtove, otherwiſe they will not thrive in this Climate.

ARMENIACA. Apricock.

ARMERIUS; Sweet William; *vide* Caryophyllus Barbatus.

ARTEMISIA, [Ἀρτεμισία, *Gr.* ſo call'd, according to ſome, of *Artemiſia* Wife of *Mauſolus* King of *Caria*, who brought this Plant into Uſe, and adopted it as hers; when before it was call'd *Parthenis*, the Virgin Goddeſs being feign'd to have given that Name to it; others derive it of Ἄρτεμις *Diana*, becauſe good for Diſeaſes of Women.] Mugwort.

The *Characters* are;

The Flowers and Fruit of this Plant are very like thoſe of the Wormwood, but grow erect upon the Branches: The Flowrets are of a purpliſh Colour; and the Leaves, for the moſt part, terminate in a ſharp Point, are cut into many Segments, and are of a dark Green on the upper Side, and hoary on the under Side.

The *Species* are;

1. ARTEMISIA *vulgaris, major, caule & flore purpuraſcentibus. C. B.* Common great *Mugwort*, with purpliſh Stalks and Flowers.

2. ARTEMISIA *vulgaris, major, caule ex viridi albicante. Tourn.* Common great *Mugwort*, with whitiſh green Stalks.

3. ARTEMISIA *foliis ex luteo variegatis. H. R. P.* The yellow ſtrip'd *Mugwort*.

4. ARTEMISIA *foliis ex albo variegatis.* The white ſtrip'd *Mugwort*.

The firſt of theſe *Species* is very common upon dry Banks and Dunghils in divers Parts of *England*, and is rarely admitted into a Garden. The ſecond Sort is a Variety of the firſt, which is rarely found in *England*: But the third and fourth Sorts are only preſerv'd in Gardens for the Beauty of their variegated Leaves. Theſe Sorts may all be propagated by parting of their Roots either in Spring or Autumn, and will grow in almoſt any Soil or Situation; but as they are ſubject to ſpread very far, and ſoon over-run a large Spot of Ground, ſo they ſhould be confin'd by cutting off their ſide Shoots to keep them within Compaſs; nor ſhould they be planted too near to other Plants, leſt, by their ſpreading Roots, they ſhould overbear and deſtroy them.

The firſt *Species* of this plant is uſed in Medicine: The Plant is commonly gather'd by the Herb-women in the Fields, and brought to the Markets: It is from one Species of *Mugwort* (and not improbably the firſt) that the famous *Moxa*, which is uſed to burn for curing the Gout, is taken, it being the *Lanugo* or downy Subſtance which adheres to the under Part of the Leaf.

ARTICHOKE, is call'd by the *Latins* Cinara.

The *Characters* are;

It is very like the Thiſtle, *but hath large ſcaly Heads, which are ſhap'd ſomewhat like the Cone of the* Pine-tree; *the Bottom of each Scale, as alſo at the Bottom of the Florets, is a thick fleſhy eatable Subſtance.*

The *Species* are;

1. CINARA *hortenſis, foliis aculeatis & non aculeatis. C. B.* The Garden Artichoke, with prickly and ſmooth Leaves.

2. CINARA *hortenſis, non aculeata, capite ſubrubente. H. R. P.* The Garden Artichoke, without Prickles, and reddiſh Heads.

3. CINARA *ſylveſtris, Bætica. Cluſ. Cur. Poſt.* The wild Artichoke of *Bætia*.

4. CINARA *ſpinoſa, cujus pediculi eſitantur. C. B. P.* The Chardon or Cardoon, *vulgô*.

I thought proper to introduce this Claſs under the Name *Artichoke*, which being the generally receiv'd Name of the only valuable Species, it might be better here plac'd than under the *Latin* Name.

ARTICHOKE.

There is at preſent but one Sort of *Artichoke* cultivated in the Gardens near *London*, which is that commonly known by the Name of the *Red Artichoke*; formerly the green Sort was the moſt common, but ſince the red Sort hath been introduc'd, the other has been rejected, as being vaſtly inferior in Goodneſs thereto.

The Manner of propagating this Plant, is from Slips or Suckers taken from the old Roots, in *February* or *March*, which, if planted in a good Soil, will produce large fair Fruit the *Autumn* following: But as this is a Plant which few Gardeners, that have not been inſtructed in the Kitchen Gardens near *London*, underſtand to manage well, ſo I ſhall be the more particular in my Directions about it.

At the latter End of *February*, or in *March*, according to the Goodneſs of the Seaſon, or Forwardneſs of the old *Artichoke* Stocks, will be proper time for dreſſing them, which muſt be thus perform'd: With your Spade remove all the Earth from about your Stock, down below the Part from whence the young Shoots are produced, clearing the Earth from between the Shoots, ſo as to be able to judge of the Goodneſs of each, with their proper Poſition upon the Stock; then make Choice of two of the cleareſt, ſtraiteſt, and moſt promiſing Plants that are produc'd from the under-part of the Stock, which you are to let remain for a Crop; then with your Thumb, force off all the other Plants and Buds, cloſe to the Head of the Stock from whence they are produc'd, and with your Spade draw the Earth about the two Plants which are left, and with your Hands cloſe it faſt to each of them, ſeparating them as far aſunder as they can conveniently be plac'd without breaking them, obſerving to crop off the Tops of the Leaves which hang down, with your Hands: Your Ground being levell'd between the Stocks, you may ſow thereon a ſmall Crop of ſpinage, which will be taken off before the *Artichokes* will cover the Ground; and be ſure to keep them clear from Weeds; and toward the latter End of *April*, or the Beginning of *May*, when your Plants begin to ſhew their Fruit, you muſt carefully look over your Stocks, and draw up all young Plants from them, which may have been produc'd ſince their Dreſſing, and cut off all Suckers which are produc'd from the Stems of the *Artichokes*, leaving only the principal Head, by which means your Fruit will be the larger; when your *Artichokes* are fit to gather, you muſt break, or cut them down cloſe to the Surface of the Ground, that your Stocks may make ſtrong freſh Shoots before *October*, which is the Seaſon for Earthing, or, as the Gardeners term it, Landing them up: which is thus done;

Cut off all the young Shoots quite cloſe to the Surface of the Ground, then dig between every Stock, raiſing all the Earth between each Row of Stocks into a Ridge, as is done in the common Method of trenching Ground, ſo as that the Row of *Artichokes* may be exactly in the Middle of each Ridge; this will be ſufficient to guard them againſt Froſt: and I would here recommend it to the Publick, as infinitely preferable to long Dung, which is by the Unſkilful often uſed, and is the Occaſion of their Fruit being ſmall, and almoſt without any Bottoms to them; for there is not any thing ſo hurtful to theſe, as new Dung being either buried near, or laid about them. Obſerve, that altho' I have mention'd *October* as the Seaſon for Earthing them, yet if the Weather proves mild, it may be deferred till any time in *November*.

When you have thus Earth'd them up, you have nothing more to do till *February* or *March*, by which time they will have grown thro' the Ridge of the Earth; and when the Weather is proper, muſt be dreſſed as was before directed.

When you have a mind to make a new Plantation, after having digged and buried ſome very rotten Dung in the Ground you have allotted for that Purpoſe, make choice of ſuch of your Plants as were taken from your old Stocks, which are clear, ſound, and not woody, having ſome Fibres to their Bottom; then with your Knife cut off that knobbed woody Part, which joined them to the Stock, and if that cuts criſp and tender, it is a Sign of its Goodneſs, but if tough and ſtringy, throw it away as good for nothing, and cut off the large outſide Leaves pretty low, that the Middle, or Heart Leaves, may be above them; your Plants being thus prepar'd, (if the Weather is very dry, or the Plants have been any time taken from the Stocks, it will be convenient to ſet them upright into a Tub of Water for three or four Hours before they are planted, which will greatly refreſh them) you muſt then proceed to Planting, which muſt be done by ranging a Line acroſs the Ground, in order to their being plac'd exactly in a Row, and with a meaſure Stick plant them at two Feet Diſtance from each other in the Rows; and if deſign'd for a full Crop, five Feet Diſtance Row from Row; your Plants muſt be ſet about four Inches deep, and the Earth cloſed very faſt to their Roots, obſerving, if the Seaſon proves dry, to keep them water'd two or three times a Week, until they are growing, after which they ſeldom require any.

N. B. You may ſow a thin Crop of Spinage upon the Ground before you plant your Plants, obſerving to clear it from about them after it is come up.

Theſe Plants, in a kindly Seaſon, or a moiſt Soil, will produce the largeſt and beſt *Artichokes*, ſome time in *Auguſt* and *September*, after all thoſe from the old Stocks are paſt; ſo that if you intend to continue you *Artichokes* thro' the whole Seaſon, you muſt plant freſh every Year, otherwiſe you can't poſſibly have Fruit longer than two Months, or ten Weeks.

If any of the Plants which you planted in the *Spring*, ſhould not Fruit in the *Autumn*, you may, at the Seaſon of Earthing your Roots, tie up the Leaves with a ſmall Willow Twig, *&c.* and lay the Earth up cloſe to it, ſo that the Top of the Plant may be above Ground; and when the Froſt comes on, if you will cover the Top with a little Straw, or Peaſe Haulm, theſe Plants will produce Fruit in *Winter*, or early in the *Spring*.

But if you intend to plant other Things between your *Artichokes*, you muſt allow nine or ten Feet between the Rows, as is often practis'd by the Kitchen Gardeners near *London*, who ſow the Ground between with Radiſhes or Spinage, and plant two Rows of Cauliflowers, at four Feet Diſtance Row from Row, and two Feet and a half Diſtance in the Rows between them; ſo that there are always five Feet allow'd for the *Artichokes* to grow; and in *May*, when the Radiſhes or Spinage are taken off, they ſow a Row of Cucumbers for Pickling, exactly between the two Rows of Cauliflowers, and at three Feet Diſtance from each other; and between the Rows of Cauliflowers and the *Artichokes*, plant a Row of Cabbages or Savoys for Winter Uſe, which, when the Cauliflowers are drawn off, and the *Artichokes* gather'd, will have full Liberty to grow; and by this means the Ground is fully employ'd thro' the whole Seaſon.

In thoſe which are planted at five Feet Diſtance Row from Row, you may plant in every other Row, a Line of Cabbages or Savoys, for Winter Uſe, which will be gone by the Time of landing them up; in the doing of which, you muſt lay the whole five Feet of Earth into one Ridge, except the Ground be extreme ſtiff, or the Plants young, in both which Caſes you may lay only three Feet and a half; the ſame Compaſs of Ground muſt alſo be allow'd where they are planted at a wider Diſtance.

And, if in the Spring, you find your Stocks ſhoot very weak, which may have been occaſion'd either by hard Froſts, or too much Wet, you muſt then uncover them, and with your Spade looſen and break the Earth about them, raiſing a ſmall Hill about each Stock, levelling the reſt between the Rows, which will greatly help them, and in three Weeks time after are commonly fit to ſlip.

Thoſe *Artichokes*, which are planted in a moiſt rich Soil, will always produce the largeſt and beſt Fruit; ſo that where ſuch a Soil can be obtain'd, it will be proper to make a freſh Plantation every Spring, to ſucceed the old Stocks, and ſupply the Table in Autumn. But the Roots will not live thro' the Winter in a very moiſt Soil, ſo that your Stocks which you intend ſhould remain, to ſupply the Table early, and to furniſh Plants, ſhould be in a drier Situation. You ſhould always obſerve to plant theſe in an open Situation, and not under the Drip of Trees, where they will draw up very tall, and produce ſmall inſignificant Fruit.

The third Sort is only preſerved in Botanick Gardens for Variety. This, and the fourth Sort, are particularly treated under the Article *Cinara*.

ARTICHOKES of *Jeruſalem*; *vide* Corona Solis.

ARTICULATION, is the Connection of Parts that conſiſt of Joints, or Knees; ſuch as are the *Siliquæ* [the Huſks] of many Plants, as of the *Ornithopodium*, *Coronilla*, which are joined together by a ſoluble Knot; whence thoſe Parts are call'd *Articuloſæ*, and are ſaid to be connected *Articulatim* or *Geniculatim*: And alſo thoſe Parts of Plants which have the ſame Form, are call'd *Articuloſæ*, altho' they have no Joints; ſo the Root of *Polygonatum* is ſaid to be *Articuloſe* or *Geniculated*.

ARUM; Wake Robin, *or* Cuckow Pint.

The *Characters* are;

The Leaves, which are intire, are long and triangular, and ear'd or darted at the Baſe; the Flower conſiſts of one Leaf, is of an Anomalous Figure, or ſhap'd like an Aſs's Ear; from the Bottom of the Flower riſes the Pointal, accompanied with a great many Embryo's, each of which becomes a roundiſh Berry, containing one or two roundiſh Seeds.

This Plant is call'd *Wake Robin*, from the ſharp acrid Taſte, which, if eaten, will occaſion a violent Pain in every Part of the Mouth and Throat, attended commonly with a great Defluxion of Water.

The *Species* are;

1. ARUM *vulgare, non maculatum. C. B. P.* Common Arum or Wake Robin.

2. ARUM *maculatum, maculis candidis. C. B. P. Arum* whoſe Leaves are mark'd with white.

3. ARUM *maculatum, maculis nigris. C. B. P. Arum* with black ſpotted Leaves.

4. ARUM *venis albis, Italicum maximum. C.B.P.* Greateſt *Italian Arum*, whoſe Leaves have white Veins.

5. ARUM *Africanum, flore albo, odorato. Par. Bat.* The *African Arum*, with white ſweet-ſmelling Flowers.

6. ARUM *eſculentum, Sagittariæ foliis viridinigricantibus. Sloan. Cat. Jam.* The *American* eatable *Arum*, with Leaves like Spearwort.

7. ARUM *maximum, Ægyptiacum, quod vulgo Colocaſia. C. B.* The *Egyptian Arum*, vulgarly call'd *Colocaſia*.

8. ARUM *maximum, Ægyptiacum, quod vulgo Colocaſia, cauliculis nigricantibus Zeylanica, H. L.* Greateſt *Egyptian Arum* or *Colocaſia*, with blackiſh Stalks.

The firſt Sort is very common under Hedges, and by the Sides of Banks, in moſt Parts of *England*. This is directed by the College of Phyſicians for medicinal Uſe; but the ſecond and third Sorts, which are Varieties of the firſt, and are often found interſperſed with it, I believe, may be either of them uſed indifferently. Theſe Plants are ſeldom kept in Gardens, being ſo common in the Fields, where they are uſually gathered for the Markets. The beſt Seaſon for taking up theſe Roots for uſe, is in *Auguſt*, after their Leaves are decayed; for when they are taken up while their Leaves are green, the Roots do ſhrink, and loſe moſt of their Virtue.

The fourth Sort is equally hardy with our common Sort, and will endure the Cold of Winters very well. This is preſerved in Botanick Gardens for Variety; but is ſeldom planted in Gardens of Pleaſure. All theſe Plants ſhould have a light dry Soil, and require no other Culture but to keep 'em clear from Weeds.

The fifth Sort produces, in the Spring, large white Flowers, upon a Pedicle four or five Feet long, making a handſome Shew in a Collection of Plants. The Flowers have a faint ſweet Scent, but continue a long time blowing.

This is propagated by parting the Roots, (which are knobbed) in *Auguſt*, when the Leaves are decay'd, and muſt be planted in Pots fill'd with good rich Earth, and hous'd in Winter with Oranges, *&c.*

The ſixth, ſeventh and eighth Sorts are tenderer, and will not live thro' the Winter without a Stove; theſe produce large fair Leaves, but have not produc'd any Flowers in *England* that I know of; the Roots of theſe three Sorts are quite of a different Nature from the other *Arums*, having a ſoft ſweet Taſte, ſomewhat reſembling that of a *Hazel Nut*, and are very much eaten in *America*, as is alſo the laſt in *Egypt*.

Theſe are propagated in the ſame manner as the firſt, but muſt be never expos'd to the open Air with us, which will ſoon deface their Leaves.

ARUNDO; the Reed.

This is diſtinguiſhed from the Graſſes by its Magnitude, and by its having a firm Stem.

The *Species* are;

1. ARUNDO *vulgaris paluſtris. J. B.* 2. 485. The common Reed.
2. ARUNDO *ſativa, quæ donax Dioſcoridis & Theophraſti. C. B. P.* The large manured Reed.
3. ARUNDO *Indica variegata, ſeu Laconica Theophraſti Cornut.* 55. The variegated Reed.
4. ARUNDO *Indica arborea*, MAMBU *vel* BAMBU *dicta.* The Bambu Cane.
5. ARUNDO *Indica arborea, amplo pediculato folio*, BAMBU SPECIES ALTERA. *Raii Hiſt.* 1316. The other Bambu Cane.
6. ARUNDO *ſaccharifera. C. B.* The Sugar Cane.
7. ARUNDO *ſcriptoria atrorubens. C.B.P.* Dark red Reed, which is uſed as a Pen for writing.
8. ARUNDO *repens vel chamæcalamus. C. B. P.* Dwarf creeping Reed.

The firſt Sort is ſo very common by the Sides of Rivers and large ſtanding Waters in divers Parts of *England*, that it is needleſs for me to ſay any thing of it's Culture. This is cut in *Autumn*, when the Leaves begin to fall, and the Stems are changed brown, for making Hedges in Kitchen Gardens, and for many other Uſes.

The ſecond Sort, altho' Native of a warm Country, yet will bear the Cold of our ſevereſt Winters in the open Ground; it dies to the Surface in *Autumn*, and riſes again the ſucceeding *Spring*; and if kept ſupplied with Water in dry Weather, will grow ten or twelve Feet high the ſame ſummer, and is very proper to intermix with ſmall Trees and Shrubs, or tall Plants and Flowers in *Boſquettes*, where, by the Oddneſs of its Appearance, it will have a good Effect, in adding to the Variety: This is propagated by parting the Roots early in the Spring, before they begin to ſhoot, and will, in a Year or two, if your Ground be good, make very large Stools; ſo that from each Clump, you may have twenty or thirty large Canes produced.

This Sort is brought from *Portugal* and *Spain*, and is uſed by the Weavers, as alſo to make fiſhing Rods.

The third Sort is a Variety of the ſecond, differing therefrom, in having variegated Leaves. This being weaken'd by the Variegation, is of much lower Growth, and is more in Danger of being deſtroyed by Froſt ſo ſhould be ſhelter'd in Winter.

The two Sorts of *Bambu* are of great Service to the Inhabitants of *India*, who make moſt of their common Utenſils of the Stems of theſe Canes, which grow to a prodigious Magnitude in thoſe Countries. In *England* they are preſerved as Curioſities, and require a Stove to preſerve them in Winter; they require a rich light Earth, and ſhould be frequently watered; their Roots ſpread very far, ſo they ſhould have a large Share of Room: I have known one of theſe Plants, when put into a large Tub, and placed in a Bark-bed in the Stove, by being often watered, produce one Stem from the Root upwards of ſixteen Feet high, in the Space of four Months. Theſe two Sorts may be propagated by Off-ſets, which they are very apt to ſet off, when they are allowed a large Share of Room for their Roots to ſpread; but if their Roots are confined, they will not thrive; when theſe Plants ſtrike their Roots thro' the Sides of their Tubs, and are permitted to run into the Bark-bed, they will thrive prodigiouſly; I have had one of theſe Plants, which was permitted to root into the Tan, which produced four Stems from the Root, each as large as a common Broom-ſtaff, and in four Months grew to be twenty Feet high.

The ſeventh Sort is what the *Turks* make their writing Pens withal; this grows in a Valley near Mount *Athos*, as alſo on the Banks of the River *Jordan*, but there are none of the Plants in *England*. This Sort may be managed as the *Bambu*, as may alſo the eighth Sort, which grows in *Arabia*.

The *Sugar Cane* is very tender, and cannot be preſerv'd without a Stove; it is kept as a great Curioſity in the Gardens of ſuch as love a Variety of Plants, as being the Plant from whence the Sugar is produc'd.

It will grow with us to the Height of eight or nine Feet, if carefully look'd after, and may be propagated by taking off the Side Shoots in the Spring, planting them in Pots of good rich Earth, plunging the Pots into a Hot-bed of Tanners-Bark, to promote their taking freſh Roots, and muſt be often watered: The main Stem is very ſubject to decay with us in Winter, but the Root commonly puſhes out many new Shoots; if this happens, you muſt mind to clear the young Shoots from the dead Leaves of the old Stem, which will greatly ſtrengthen them.

ASARUM; [of α Privative, and σαίρω, *Gr.* to adorn, as much as to ſay, a Plant fit for no Ornament.] Aſarabacca.

The *Characters* are;

The Calyx (or Flower Cup) is divided into four Parts; the Fruit is divided into ſix Cells, which are fill'd with oblong Seeds; to which may be added, the Leaves are roundiſh, thick, and almoſt of the Colour of thoſe of the Ivy Tree.

There are two *Species* of this Plant in the *Engliſh* Gardens; *viz.*

1. ASARUM. *C. B.* The common Aſarabacca.
2. ASARUM *Canadenſe. Cornut.* The *Canada* Aſarabacca.

The firſt of theſe Sorts is very common, and hath been found wild in ſome Parts of *England*, tho' but rarely; it delights in a moiſt ſhady Place, and is increas'd by parting the Roots in *Autumn*: This is the Sort which is uſed in Medicine.

The *Canada* Sort is tolerably hardy, and will endure our common Winters in the open Ground, being rarely hurt but by great Froſts, or planting it in a wet Soil. This is propagated as the other.

Both theſe Sorts preſerve their green Leaves in Winter, which decay as their new ones are produc'd: Their Flowers appear in *April*, which grow ſo cloſe to the Ground as not to be ſeen, unleſs you put away the Leaves with your Hand: The firſt Sort produces ripe Seeds, but it is not worth the Trouble of ſowing, it being two Years before theſe Plants will have any Strength, and they are much eaſier rais'd by Slips. The ſecond very rarely produces good Seeds in *England*.

ASCLEPIAS, [is ſo call'd of *Æſculapius* the firſt Founder of Phyſick; and the Plant deſervedly bears that Name, becauſe of its excellent Virtues; It is alſo call'd *Vincetoxicum* of *Vincere*, to overcome, and τοξικὰ Poiſons, *q. d.* a Plant overcoming Poiſons.] Hirundinaria *or* Swallow-wort.

The *Characters* are;

It hath a Flower conſiſting of one Leaf, which is divided into five Parts, expanded in Form of a Star: The Ovary becomes a Fruit, which is for the moſt part compos'd of two membraneous Huſks, which open from the Bottom to the Top, incloſing many Seeds, which are cover'd with a fine Down, and are fix'd to the Membrane, like as Scales are diſpos'd upon the Skins of Fiſhes: This Plant hath no milky Juice, wherein it differs from the Dogsbane.

The *Species* are;

1. ASCLEPIAS *albo flore. C. B.* The common Swallow-wort, with white Flowers.
2. ASCLEPIAS *nigro flore. C. B.* The common Swallow-wort, with black Flowers.
3. ASCLEPIAS *anguſtifolia, flore flaveſcente. H. R. Par.* The narrow-leav'd Swallow-wort, with yellow Flowers.
4. ASCLEPIAS *Africana, aizoides. Tourn.* The *African* Swallow-wort, *commonly called*, Fritillaria Craſſa.
5. ASCLEPIAS *Africana, aizoides, flore pulchrè fimbriato. Com. Rar.* The *African* Swallow-wort, with fair hairy Flowers, *commonly called*, Fritillaria Craſſa major.
6. ASCLEPIAS *Africana, aizoides, folio compreſſo digitato & criſtato. Boerh. Ind.* The *African* Swallow-wort, with creſted Leaves, *commonly called*, The Cockſcomb Fritillaria.

The three firſt Sorts are very hardy, and will endure the Winter's Cold in the open Ground; the firſt Sort is ſometimes uſed in Medicine, and is for that Purpoſe preſerv'd in the Phyſick Gardens; they are all three of them propagated by parting their Roots, either in *Spring* or *Autumn*, and will grow in almoſt any ſort of Soil; they may be alſo rais'd from Seeds, which muſt be ſown early in the *Spring*, in a Bed of common Earth, and the ſecond Year the young Plants will produce Flowers, but theſe rarely produce any good Seeds in *England*.

The fourth, fifth, and ſixth Sorts, are Natives of the *Cape of Good Hope*, and were firſt brought from thence into the *Dutch* Gardens, and were afterwards brought into *England*; theſe Plants are propagated by planting Cuttings in any of the Summer Months, which Cuttings ſhould be taken from the Plants, at leaſt a Week before they are planted, and laid in a dry Place, that the Wound may be heal'd, and the Moiſture evaporated, otherwiſe they are very ſubject to rot: theſe Cuttings muſt be planted in ſmall Pots fill'd with a ſandy Soil; and after having ſtood about a Week abroad in a ſhady Place, you may plunge the Pots into a very moderate Hot-bed, which will greatly forward their making new Roots; in about a Month's Time after planting, you muſt begin to harden them, by expoſing them to the open Air, but do not let them receive much Wet, which is a great Enemy to theſe Plants; and in the Beginning of *September*, you muſt houſe them with the ſmaller Sorts of *Aloes*, giving them very little Water in the Winter Seaſon.

The fifth Sort is very ſubject to flower every Year, but the fourth and ſixth Sorts flower but ſeldom; but neither of them is ſo apt to flower, if expos'd to the open Air in Summer; therefore it is the better way to let them remain in the Houſe moſt part of the Year, giving them as much free Air as poſſible, when the Weather will permit, and never letting them have much Water: With this Management all the Sorts will thrive much better, and oftener produce Flowers.

Altho' there is no great Beauty in theſe Flowers when blown, yet for their extreme Oddneſs they well deſerve a Place in every curious Collection of Plants.

Theſe Flowers ſo much reſemble in Smell ſtinking Fleſh, that the Flies will cover them with their Eggs, which come ſo far as juſt to have Life; but not finding proper Nutriment, they ſoon periſh.

ASCYRUM; [Ἄσκυρον, of *α* Privative, and σκύρον, Roughneſs, *q. d.* the ſmooth or bald Plant.] St. Peter's-wort.

The *Character* is;

This Plant differs from St. John's-wort, *only in having a Pyramidal Seed Veſſel, which is divided into five Cells.*

We have only two Sorts of this Plant in *England*; *viz.*

1. ASCYRUM *magno flore. C. B. P.* The large flowering St. Peter's-wort.
2. ASCYRUM *Balearicum, fruteſcens, maximo flore luteo, foliis minoribus, ſubtus verrucoſis. Salvador. Boerh. Ind. Myrto-Ciſtus Penæi. Cluſ. H.* The large flowering St. Peter's-wort from *Majorca*, with ſmall warted Leaves.

The firſt of theſe Plants was ſent into *England* by Sir *George Wheeler*, to the Phyſick Garden at *Oxford* from *Conſtantinople*, where he found it wild; this Plant produces very large Flowers, with a great Number of Stamina or Threads in the Middle, and makes a very agreeable Shew in the Wilderneſs Quarters, or in ſhady Borders, where it chiefly delights to grow: It is very hardy, and increaſes greatly by its creeping Roots, which will ſoon overſpread a Border; it is beſt when kept in ſmall Tufts, and not ſuffer'd to run too much, which often prevents its flowering, by having too great a Quantity of Branches; the Flowers are produc'd in *June* and *July*, but it ſeldom perfects its Seeds with us. This will grow in almoſt any Soil.

The ſecond Sort was firſt mention'd by Dr. *Lobel*, who receiv'd a dried Sample of this Plant from Dr. *Pennæ*, who found it in *Majorca* when on his Travels, and was by *Lobel* call'd *Myrto-Ciſtus*; the Flowers, as he thought, reſembling the *Ciſtus* or *Rock Roſe*, and the Leaves thoſe of the *Myrtle*.

But this Plant was not known to any of the modern Botaniſts, until one *Salvadore*, an Apothecary, who liv'd at *Barcelona*, went into thoſe Iſlands in ſearch of Simples, where he found this Plant, and ſending ſome Specimens thereof into *England* and *Holland*, which had ſome ripe Seeds in their Veſſels, they were ſown, and grew, from whence this Plant hath been ſpread into many curious Gardens.

This Plant is propagated, either from Seeds ſown on a moderate Hot-bed in the Spring, or by planting Cuttings in the Summer Months in Pots of good Earth, which ſhould be plung'd into an old Hot-bed, and kept water'd and ſhaded in the Heat of the Day, until they have taken Root, when you may by degrees expoſe it to the open Air, but it muſt be hous'd in Winter with *Myrtles*, *Amomum Plinii's*, &c. being too tender to endure the Cold of our Winters in the open Ground, but may, with a ſlight Shelter, be eaſily preſerv'd. It requires frequent, but gentle Waterings, and loves a looſe ſandy Soil, with a ſmall Mixture of very rotten Dung.

This is worthy of a Place in every curious Collection of Plants, for the Beauty of its red Shoots, ſmall criſp'd Leaves, and its continuing to flower moſt part of the Year.

ASH-TREE. *Vide* Fraxinus.

ASHES are eſteem'd by ſome a good ſuperficial Dreſſing of Corn and Meadow Land, as they give a new Ferment to ſuch Lands as are in any Degree ſluggiſh and unactive, and inrich thoſe which are jejune and ſlow, being endow'd with ſingular Qualities to make them prolifick.

All Sorts of *Aſhes* do, indeed, contain in them a very rich fertile Salt, and are the beſt Manure of any to lay upon cold, wet Land, but then they ought to be kept dry, that the Rain may not waſh away their Salt. Experience has ſhewn, that the *Aſhes* of any Sort of Vegetable are very advantageous to Land, by the Improvement that has been made in moſt Places in *England*, by burning Bean Stalks, Fern, Furze, Heath, Sedge, Straw, Stubble, *&c.*

Coal-Aſhes, or ſuch as are made of *New-caſtle*, *Scotch*, and other Pit-Coal, are much recommended by ſome; but the firſt are moſt approv'd of, becauſe they contain a greater Quantity of nitrous and ſulphureous Matter than the others do, tho' the reſt are good.

But theſe ought to be apply'd ſuperficially, and not ſo near the Roots of Plants; and if ſo, there are few Plants but will receive Benefit by them, by their nitrous and ſulphureous Qualities, being waſh'd down by the Rain, which will open by the Strength of Water, and cauſe it to heave in ſome Degree, as Lime will do when Water is thrown upon it.

Wood-Aſhes are commended as the Principal of ſuperficial Dreſſings for Land, in that they contain a vegetative kind of Salt.

Kiln-Aſhes, *i. e.* ſuch as are made of Straw, Furze, *&c.* are by ſome accounted as good as any of the ſpirituous Improvements of Lands that are lightiſh; but for ſuch as are heavy, they are look'd upon as ſcarce ſolid and ponderous enough. Theſe *Aſhes*, the Maltſters in the *Weſt-Country* ſift over their Corn and Graſs. Theſe are ſuppos'd, by their Heat, to cauſe a Fermentation, a Hollowneſs and Looſeneſs in the Mould, by which means the Rains enter it the more eaſily, and diſpoſe the Earth for giving up an Aſſumption of its vegetative Augment.

But theſe being light, ought never to be ſtrew'd nor ſifted in windy Weather, becauſe they would be blown away; and if it can be ſo order'd as to be done juſt before Snow or Rain, it would be the better.

Soap-Aſhes, (*i. e.* after the Soap-Boilers have done with them) are very proper for Lands that are very cold and ſour, and to kill Weeds of all Sorts: And Sir *Hugh Plat* mentions one at *Ware*, who having a Piece of Land over-run with Broom and Furze, manur'd it with *Soap-aſhes*, and had an incredible Crop of Wheat for ſix Years ſucceſſively.

Pot-Aſhes, after the Pot-aſh Men have done with them, are eſteem'd good for moſt Sorts of Land; but as they have been wet, and ſo moſt of the Salt drawn off by the Lee, they ought to be laid on much thicker than other Aſhes.

Turf-Aſhes are very good for all Sorts of Land, but eſpecially for Clay-Lands; but will be much better if mix'd with Lime.

But all theſe *Aſhes* ought to be kept dry from the Time they are made till they are uſed, for elſe the Rains will both waſh away their Goodneſs, and alſo make them clod, eſpecially ſome of the laſt-mention'd, ſo that they will not ſpread.

And beſides, one Load of *Aſhes* that have been kept dry, will go as far as two that have been expos'd to the Rain: And *Coal-Aſhes*, if moiſten'd with Chamber-lye or Soap-ſuds, will greatly add to their Strength.

All calcin'd Vegetables cauſe a fiery Heat and Vegetation, and when Wet comes, ſet the Ground to work, by a ſubtle Inſinuation, unlocking the Clods, and quickening the Sluggiſhneſs of the Earth; according to that eſtabliſh'd Maxim among Naturaliſts, *That all Fermentation is caus'd by the Interpoſition or Mixture of different Qualities one from the other.*

It is after this manner that *Coal-aſhes* operate ſo admirably in looſening and mouldering ſtiff, clayey Grounds, and as it is uſually term'd, making it rough, aſhy or ſandy-like: And, after the ſame manner, Sand mix'd with Clay does well, eſpecially when it is impregnated with ſaline Qualities.

ASPARAGUS, the firſt Sprigs of Herbs before unfolded into Leaves; and the youngeſt and tendereſt Branches that are eatable, are call'd *Aſparagus*.

ASPARAGUS: ['Ασπαραγὸς, *Gr.* ſignifies a young Shoot putting forth.] *Aſparagus*, Sparagus or Sperage, corruptly call'd Sparrow-graſs.

The *Characters* are;

It hath a roſaceous Flower, conſiſting of ſix Leaves, placed orbicularly, out of whoſe Centre riſes the Pointal, which afterwards turns to a ſoft Fruit, or almoſt globular Berry, and full of Seeds, which are commonly hard. To theſe Marks may be added, that the Leaves are finely cut.

The *Species* are;

1. Asparagus *ſativa. C. B. P.* 489. Garden Aſparagus.
2. Asparagus *ſylveſtris, tenuiſſimo folio. C. B. P.* 489. Wild Aſparagus with narrow Leaves.
3. Asparagus *maritimus, craſſiore folio. C. B. P.* 489. Sea Aſparagus with a thick Leaf.
4. Asparagus *aculeatus, ſpinis horridus. C. B. P.* 490. Prickly Aſparagus
5. Asparagus *foliis acutis. C. B. P.* Sharp leav'd Aſparagus.
6. Asparagus *aculeatus alter, tribus aut quatuor ſpinis ad eundem exortum. C. B. P.* Another prickly Aſparagus with three or four Spines riſing at the ſame Place.
7. Asparagus *aculeatus Africanus. H. L.* Prickly *African* Aparagus.
8. Asparagus *aculeatus maximus ſarmentoſus Zeylanicus. H. L.* The largeſt prickly buſhy Aſparagus of *Ceylon.*
9. Asparagus *Hiſpanicus, aculeis craſſioribus horridus. Inſt. R. H.* Spaniſh Aſparagus with terrible thick Prickles.
10. Asparagus *Creticus fruticoſus, craſſioribus & brevioribus aculeis, magna fructu. Tourn. Cor.* Shrubby Aſparagus of *Candy*, with thick and ſhort Prickles, and large Fruit.
11. Asparagus *orientalis, foliis gallii. Tourn. Cor.* Oriental Aſparagus with Ladies-Bed-ſtraw Leaves.
12. Asparagus *Africanus ſcandens, myrti folio anguſtiore. Hort. Piſſ.* Climbing *African* Aſparagus with a narrow Myrtle-leaf.

The firſt Sort here mentioned is that which is generally cultivated in Gardens for the Uſe of the Table, whoſe tender Shoots are eaten in the Spring, and are much eſteemed by all delicate Palates.

It is propagated by ſowing of the Seeds; in the procuring of which, you ſhould be particularly careful, ſince the Goodneſs of your future Crop, in a great meaſure, depends thereon: You ſhould therefore get it from ſome Perſon of Integrity, or if you have an Opportunity of ſaving it yourſelf, or in ſome other neighbouring Garden: You muſt look over the *Aſparagus* Beds in the Beginning of the Seaſon, and mark ſome of the largeſt and faireſt Buds with a Piece of Stick; which Buds, when they have branched out, may be faſten'd to Stakes thruſt into the Ground to preſerve them from breaking: Theſe Buds will many of them produce great Numbers of red Berries, which ſhould be ſuffer'd to remain upon the Branches until the latter End of *September*, when the Haulm will begin to decay; then cut off the Branches, and ſtrip the Berries into a Tub, where they may lie in a Heap to ſweat for three Weeks, by which means the outer Huſks will be rotten; then fill the Tub with Water, and with your Hands break all the Huſks by ſqueezing them between your Hands: Theſe Huſks will all ſwim upon the Water, but the Seeds will ſink to the Bottom, ſo that by pouring off the Water gently, the Huſks will be carry'd along with it, and by putting freſh Water two or three times, and ſtirring your Seed about, you will make it intirely clean; then ſpread your Seed upon a Mat, and expoſe it to the Sun and Air in dry Weather, until it is perfectly dry; when you may put it into a Bag, and hang it up in a dry Place till the Beginning of *February*; at which Time you muſt prepare a Bed of good rich Earth, whereon you muſt ſow your Seeds, (but not too thick, which will cauſe your Plants to be ſmall) and having trod your Seed into the Ground, rake it over ſmooth.

In the following Summer, keep it diligently clear'd from Weeds, which will greatly add to the Strength of your Plants; and toward the latter End of *October*, when the Haulm is quite wither'd, you may ſpread a little rotten Dung over the Surface of the Ground, about half an Inch thick, which will preſerve the young Buds from being hurt with the Froſts, *&c.*

The Spring following, your Plants will be fit to plant out for good, (for I would never chuſe Plants of more than one Year's Growth, having very often experienc'd them to take much better than older, and to produce finer Roots); you muſt therefore prepare your Ground by trenching it well, burying therein a good Quantity of rotten Dung at the Bottom of each Trench, ſo that it may lie at leaſt ſix Inches below the Surface of the Ground; then level your whole Plot very exactly, taking out all large Stones; but this ſhould not be done long before you intend to plant you *Aſparagus*, in which you muſt be govern'd according to the Nature of your Soil or the Seaſon; for if your Soil is dry, and the Seaſon forward, you may plant early in *March*; but in a wet Soil, it is better to wait till the End of that Month, or the Beginning of *April*, which is about the Seaſon that the Plants are beginning to ſhoot. I know many People have adviſ'd the planting of *Aſparagus* at *Michaelmas*; but this I have experienc'd to be very wrong, for in two different Years I was obliged to tranſplant large Quantities at that Seaſon, but I had better thrown away the Plants, for upon Examination, in the Spring, I found moſt of the Roots were grown mouldy and decaying, and I am ſure not one in five of them ſucceeded, and thoſe which did, were ſo weak as not to be worth their ſtanding.

The Seaſon being now come, you muſt, with a narrow-prong'd Dung-fork, carefully fork up your Roots, ſhaking them out of the Earth, and ſeparating them from each other, obſerving to lay their Heads even for the more convenient planting them, which muſt be perform'd in this manner.

Your Plot of Ground being levell'd, you muſt begin at one Side thereof, ranging a Line very tight croſs the Piece, by which you muſt throw out a Trench exactly ſtrait, and about ſix Inches deep, into which you muſt lay your Roots, ſpreading them with your Fingers, and placing them upright againſt the back of your Trench, ſo that the Buds may ſtand forward, and be about two Inches below the Surface of the Ground, and at twelve Inches Diſtance from each other; then with a Rake draw the Earth into the Trench again, laying it very level, which will preſerve the Roots in their right Poſition: Then remove your Line a Foot farther back, and make another Trench in the like manner, laying therein your Plants, as before directed, and continuing the ſame Diſtance Row from Row, only obſerving between every four Rows to leave a Diſtance of two Feet four Inches for an Alley to go between the Beds to cut the *Aſparagus*, &c.

Your Plot of Ground being finiſh'd and levell'd, you may ſow thereon a ſmall Crop of Onions, which will not hurt your *Aſparagus*, and tread in your Seeds, raking your Ground level.

When your *Aſparagus* is come up, (which will be in three Weeks or a Month after planting) you muſt with a ſmall Hough cut up all the Weeds, and thin your Crop of *Onions* where they may have come up in Bunches: But this muſt be done carefully, and in dry Weather, that the Weeds may die as faſt as they are cut up. This Work muſt be repeated about three times; which if well done, and the Seaſon not too wet, will keep the Ground clear from Weeds until the *Onions* are fit to be pull'd up, which is commonly *Auguſt*, and is known when their Greens fall down: when you have drawn off your *Onions*, you muſt clean your Ground well from Weeds, which will keep it clean till you earth the Beds; which muſt be done in *October*, when the Haulm begins to decay, for if you cut off the Haulm while green, the Roots will ſhoot freſh again, which will greatly weaken them: This young Haulm ſhould be cut off with a Knife, leaving the Stems two or three Inches above Ground, which will be a Guide for you to diſtinguiſh the Beds from the Allies; then with a Hough clear off all the Weeds into the Allies, and dig up the Allies, burying the Weeds in the Bottom, and throw the Earth upon the Beds, levelling it even, ſo that the Beds may be about five Inches above the Level of the Allies; then you may plant a Row of *Colworts* in the Middle of the Allies, but do not ſow or plant any thing upon the Beds, which would greatly weaken your Roots; nor would I ever adviſe the planting of *Beans* in the Allies, (as is the Practice of many) for it greatly damages the two out-ſide Rows of *Aſparagus*. In this manner it muſt remain till Spring, when you muſt hough over the Beds to deſtroy all young Weeds, and rake them ſmooth, and obſerve all the ſucceeding Summer to keep them clear from Weeds; and in *October* dig up the Allies again, as was before directed, earthing the Beds, *&c.*

The ſecond Spring after planting, you may begin to cut ſome of your *Aſparagus*; therefore now you muſt fork up your Beds with a flat prong'd Fork made on purpoſe, which is commonly call'd an *Aſparagus*-fork: This muſt be done before the Buds ſhoot in the Spring, and with Care, not to fork too deep, ſo as to bruiſe the Head of the Root; then rake the Beds over ſmooth, juſt before the Buds appear above Ground, which will deſtroy all young Weeds, and keep your Beds clean a great while longer than if left unrak'd, or done ſo ſoon as fork'd; and when your Buds appear about four or five Inches above Ground, you may then cut them; but it ſhould be done ſparingly, only taking the large Buds, and ſuffering the ſmall to run up to ſtrengthen the Roots; for the more you cut, the more the Roots will produce, but they will be the ſmaller, and ſooner decay. When you cut a Bud, you muſt open the Ground with your Knife, (which ſhould be very narrow and long in the Blade, and filed with Teeth like a Saw) to ſee whether there are any more young Buds coming up cloſe by it, which might be either broken or bruis'd in cutting the other; then with your Knife ſaw it off about two Inches under-ground. This may appear a very troubleſome Affair to People unacquainted with the practical Part; but thoſe who are employ'd in cutting *Aſparagus*, will perform a great deal of this Work in a ſhort Time; but the Care in doing it is abſolutely neceſſary to be obſerv'd by all who cut *Aſparagus.*

The manner of dreſſing your *Aſparagus* Beds is every Year the ſame as directed for the ſecond, *viz.* keeping them clear from Weeds, digging the Allies in *October*, and forking the Beds towards the End of *March*, *&c.* only obſerve every other Year to lay a little rotten Dung (from a *Melon* or *Cucumber* Bed) all over your Beds, burying ſome in the Allies alſo, at the Time for digging them up: This will preſerve the Ground in Heart to maintain your Roots in Vigour; and by which Management a Plot of good *Aſparagus* may be continued for ten or twelve Years in Cutting, and will produce good Buds.

The Quantity of Ground neceſſary to be planted with *Aſparagus*, to ſupply a ſmall Family, ſhould be at leaſt eight Rods; leſs than that will not do; for if you cannot cut one hundred at a time, it will ſcarcely be worth while; for you muſt be oblig'd to keep it after it is cut, two or three Days to furniſh enough for one Meſs; but for a larger Family, ſixteen Rods of Ground ſhould be planted, which, if a good Crop, will furniſh two or three hundred each Day in the Height of the Seaſon.

But as there are ſeveral People who delight in having early *Aſparagus*, which is become a very great Trade in the Kitchen Gardens near *London*, ſo I ſhall give proper Directions for the obtaining it any time in Winter.

You muſt firſt be provided with a Quantity of good Roots, (either of your own raiſing, or purchas'd from ſuch Gardeners as plant for Sale) that have been two Years planted out from the Seed-bed; and having fix'd upon the Time when you would willingly have your *Aſparagus* fit to cut, about ſix Weeks before, you ſhould prepare a Quantity of new Stable Horſe-dung, which ſhou'd be thrown in a Heap for a Week or more, to ferment; then dig out a Trench in the Ground where you intend to make the Bed, the Width of the Frames that are deſign'd to cover it, and the Length in proportion to the Quantity you intend to have, (which if deſign'd only to ſupply a ſmall Family, three Lights at a time will be ſufficient): Then lay down your Dung into the Trench, working it very regularly, and beat it down very tight with a Fork, laying it at leaſt three Feet in Thickneſs; then put your Earth thereon about ſix Inches thick, breaking the Clods, and laying it level, and at one End begin laying your Roots againſt a little Ridge of Earth, rais'd about four Inches high: Your Roots muſt be laid as cloſe as poſſible one to the other in Rows with their Buds ſtanding upright: and between every Row lay a ſmall Quantity of fine Mould, obſerving to keep the Crown of the Roots exactly level: When you have finiſh'd laying your Bed with Roots, you muſt lay ſome ſtiff Earth up to the Roots on the Out-ſides of the Bed, which are bare, to keep them from drying, and thruſt two or three ſharp-pointed Sticks, about two Feet long, down between the Roots in the Middle of the Bed at a Diſtance from each other. The Uſe of theſe Sticks is to let you know what Temper of Heat your Bed is in, which you may find by drawing up the Sticks, and feeling the lower Part; and if, after the Bed has been made a Week, you find it doth not heat, you may lay a little Straw or Litter round the Sides, or upon the Top, which will greatly help it; and if you find it very hot, it will be adviſeable to let it remain wholly uncover'd, and to thruſt a large Stick into the Dung on each Side of the Bed in ſeveral Places, to make Holes for the great Steam of the Bed to paſs off, which in a ſhort time will reduce the Bed to a moderate Heat.

After your bed has been made a Fortnight, you muſt cover the Crowns of the Roots with fine Earth about two Inches thick; and when the Buds appear above Ground through that Earth, you muſt again lay on a freſh Parcel about three Inches thick; ſo that in the Whole it may be five Inches above the Crowns of the Roots, which will be ſufficient.

Then you muſt make a Band of Straw (or long Litter) about four Inches thick, which you muſt faſten round the Sides of the Bed, ſo that the upper Part may be level with the Surface of the Ground; This muſt be faſten'd with ſtrait Sticks about two Feet long, ſharpen'd at the Points to run into the Bed, and upon this Band you muſt ſet your Frames, and put your Glaſſes thereon; but if after your Bed hath been made three Weeks, you find the Heat decline, you muſt lay a good Lining of freſh hot Dung round the Sides of the Bed, which will add a freſh Heat thereto; and in bad Weather, as alſo every Night, keep the Glaſſes cover'd with Mats and Straw, but in the Day-time let it be all taken off, eſpecially whenever the Sun appears, which ſhining through the Glaſſes, will give a good Colour to the *Aſparagus.*

A Bed thus made, if it works kindly, will begin to produce Buds for cutting in about five Weeks, and will hold about three Weeks in cutting, which, if rightly planted with good Roots, will produce in that time about three hundred Buds in each Light; ſo that if you would continue your *Aſparagus* until the Seaſon of the Natural being produc'd, you muſt make a freſh Bed every three Weeks, until the Beginning of *March*, from the Seaſon of your firſt Bed being made; for if your laſt Bed is made about a Week in *March*, it will laſt till the Seaſon of natural *Aſparagus*, and the laſt Beds will come a Fortnight ſooner to cut than thoſe made about *Chriſtmas*, and the Buds will be larger and better coloured, as they enjoy a greater Share of the Sun.

If you intend to follow this Method of forcing early *Aſparagus*, you muſt keep planting every Year a Quantity which you ſhall judge neceſſary, (unleſs you intend to buy it from ſome other Garden): The Quantity of Roots neceſſary to plant one Light, is commonly known by the Meaſure of the Ground where they grew; for in a good Crop, where few Roots are miſſing, one Rod of Ground will furniſh enough for a Light: but thoſe who plant *Aſparagus*, with a Deſign to take it up for Forcing at two Years end, plant ſix Rows in each Bed, at ten Inches diſtance only, and lay the Plants in the Rows about eight Inches aſunder, which will be a ſufficient Diſtance, as they are deſigned to remain but two Years. The beſt Ground for planting *Aſparagus* to have large Roots for Hot-beds, is a low, moiſt, rich Soil; but for thoſe that are to remain for a natural Produce, a middling Soil, neither too wet nor too dry: but a freſh ſandy Loam, when well dunged, is preferable to any other.

The ſecond Sort grows wild in the Fens of *Lincolnſhire*, and ſome other Parts of *England*; but this producing very ſlender Shoots, is rarely cultivated in Gardens. Tho' a Friend of mine, who had cultivated this Sort for ſome Years, aſſured me, it was ſweeter, and would come earlier in the Spring (without artificial Heat) than the Garden Kind.

All the other Sorts are preſerved in the Gardens of thoſe Perſons who are Lovers of Botany for Variety. Theſe may be all propagated by Seeds, which ſhould be ſown in Pots filled with light freſh Earth early in the Spring; theſe Pots may be placed on a moderate Hot-bed, which will greatly forward the Vegetation of the Seed: when the Plants begin to appear, they ſhould be inured to the open Air by Degrees, and muſt be kept clear from Weeds, as alſo in dry Weather muſt be frequently refreſhed with Water. In the Autumn theſe Pots muſt be either removed into the Green-houſe, or placed under a Hot-bed Frame, where they may be protected from Froſt; for as they are Natives of warm Countries, ſo they will not endure the Cold of our Climate in Winter: the Spring following, juſt before the Plants begin to ſhoot, the Roots ſhould be turned out of the Pots, and the Earth gently ſeparated from them; then they ſhould be parted, and as many of the beſt Roots as are intended to be preſerved, ſhould be planted each into a ſeparate Pot filled with light freſh Earth, and then placed on a very moderate Hot-bed, covered only with Mats, juſt to promote their new Roots, and when the Weather is mild, they may be expoſed to the open Air; theſe Plants may be placed abroad during the Summer Seaſon, but in Winter they muſt be protected from hard Froſt, which will otherwiſe deſtroy them. The only Culture which theſe Sorts require, is, to ſhift them every Spring into freſh Earth juſt before they begin to ſhoot; and as their Roots increaſe in Magnitude, ſo they ſhould be allowed larger Pots. In Summer they muſt be frequently watered, but in Winter, when their Green is decayed, they ſhould not have too much Water, leſt it rot them.

The laſt Sort never produces ripe Fruit in this Country, but it increaſes plentifully by Off-ſets, which ſhould be taken off in the Spring, before they ſhoot, otherwiſe they do not ſucceed ſo well. The Roots of this Sort are very ſubject to rot, where they have too much Wet in Winter.

ASPEN-Tree. *Vide* Populus.

ASPERIFOLIOUS *Plants*, [*Aſperifolius*, of *Aſper*, rough, and *Folium*, *Lat.* a Leaf] are ſuch Plants as are rough-leaved, having their Leaves placed alternately, or without any certain Order on their Stalks; they have a monopetalous Flower cut or divided into five Parts; after every Flower there ſucceed commonly four Seeds: Of this Claſs are *Bugloſs*, *Borage*, *Comfrey*, *Hounds-tongue*, &c.

ASPERUGO; Small wild Bugloſs.

The *Characters* are;

It hath a Flower conſiſting of one Leaf, which is ſhaped like a Funnel, and cut into ſeveral Segments; out of whoſe Empalement riſes the Pointal, fixed in the Bottom of the Flower, ſurrounded by four Embryo's, which afterwards become ſo many oblong Seeds, which ripen in the Empalement, that is much inlarged, whoſe Parts are then ſo cloſely contracted, that they adhere and cling together.

We have but one Sort of this Plant, which is,

ASPERUGO *vulgaris. Inſt. R. H.* Small wild Bugloſs, great Gooſe-graſs, or *German* Madwort.

This is an annual Plant, which is found wild in ſome Parts of *England*, as near *Newmarket*, at *Boxley* in *Suſſex*, and in *Holy Iſland.* It is preſerved in the botanick Gardens for Variety; it may be eaſily propagated by Seeds, which ſhould be ſown in Autumn; for if the Seeds are kept out of the Ground till Spring, they do not ſucceed ſo well: when the Plants come up, they require no other Culture but to keep them clear from Weeds, and in *May* they will flower; in *June* their Seeds will be perfected, which if ſuffered to ſcatter, will grow again in Autumn; ſo that when this Plant is once brought into a Garden, it will maintain itſelf, provided it be allowed a Place.

ASPERULA, Woodroof.

This Plant grows wild in ſhady Woods in many Parts of *England*, and flowers in *April* and *May*, and is ſometimes uſed in Medicine.

ASPHODELUS, [ʼΑσφόδελος of ἀσφαλὴς, *Gr.* Firm; and by *Pliny* it is called *Haſtula*, or *Baccillus Regius*, becauſe when it flowers, the Stalk reſembles a Royal Sceptre; it is the ſame Herb which is called alſo *Antiricon*, with which, as *Lucian* feigns, the Manes or Ghoſts are fed in *Pluto*'s Dominions] Kingſpear.

The *Characters* are;

The Stalk is round, ſmooth, ſtrong, and branchy; the Leaves are like thoſe of a Leek, but ſtronger and narrower; the Flowers are divided commonly as far as the Baſis, naked, ſtellated, embracing the Ovary like a Calyx: the Apex of the Ovary puts forth ſix Stamina, and a long Tube from the Center, which becomes a roundiſh Fruit, carnous, triangular, and divided into three Partitions, in which are incloſed triangular Seeds.

There are three or four Varieties of this Plant, which are well worth preſerving in all Flower-Gardens; *viz.*

1. ASPHODELUS *luteus & flore & radice. C. B.* The yellow Aſphodel *or* Kingſpear.
2. ASPHODELUS *albus, ramoſus, mas. C. B.* The great white branching Aſphodel *or* Kingſpear.
3. ASPHODELUS *albus, non ramoſus. C. B.* The white unbranched Aſphodel *or* Kingſpear.
4. ASPHODELUS *Allobrogicus, magno flore Lilii. H. L.* The large flowering *Savoy* Aſphodel *or* Kingſpear.

Theſe Plants are all of them extreme hardy, and will proſper in almoſt any Soil, that is not too ſtiff or wet, which is ſubject to rot the Roots in Winter: The Way to increaſe them is, by parting their Roots in *Auguſt*, before they ſhoot up their freſh green Leaves. Theſe Plants growing pretty tall, are proper for large Borders, or to mix with Flowers of large Growth, in ſmall Quarters or Boſquets in Wilderneſs-work, but muſt not be planted in Borders of ſmall Flowers, where, by their large ſpreading Roots, they would deſtroy their weaker neighbouring Plants.

The yellow Sort multiplies very faſt by Roots, and will ſoon overſpread a large Border, if ſuffered to remain unremoved, or the Side-Roots are not taken off: But the other Sorts are not ſo productive of Shoots from their Sides, and are much better kept within Bounds. They may all be raiſed from Seeds, which ſhould be ſown in *Auguſt*; and the *Auguſt* following, may be tranſplanted out into Nurſery-beds or Borders, and will produce Flowers the ſecond Year. The yellow and large-branched *Aſphodels* are ſometimes uſed in Medicine.

To this Article add;

1. ASPHODELUS *albus ramoſus minor, ſeu ramoſus alter. H. R. Par.* Small white branched Aſphodel *or* Kingſpear.
2. ASPHODELUS *purpuraſcens, foliis maculatis. C. B. P.* Purpliſh Aſphodel with ſpotted Leaves.
3. ASPHODELUS *foliis compreſſis aſperis, caule patulo. Inſt. R. H.* Aſphodel with rough compreſſed Leaves, and a ſpreading Stalk.
4. ASPHODELUS *Africanus anguſtifolius luteus minor. Inſt. R. H.* Small yellow *African* Aſphodel with narrow Leaves.
5. ASPHODELUS *ſpiralis luteus Italicus, flore magno. H. R. Par.* Yellow ſpiral *Italian* Aſphodel, with a large Flower.
6. ASPHODELUS *albus minimus. C. B. P.* Smalleſt white Aſphodel.
7. ASPHODELUS *foliis fiſtuloſis. C. B. P.* Aſphodel with fiſtulous Leaves.
8. ASPHODELUS *Creticus luteus ſerotinus patulus, folio aſpero. Tourn. Cor.* Late yellow ſpreading Aſphodel of *Candy*, with a rough Leaf.

All the Sorts of Aſphodel are very pretty Ornaments for a Flower-garden, and requiring very little Trouble to cultivate them, renders them more acceptable. They may be all propagated by Seeds, which ſhould be ſown ſoon after they are ripe, on a warm Border of light freſh Earth; in the Spring the Plants will appear, when you ſhould carefully clear them from Weeds, and in dry Weather they muſt be frequently watered; if this be duly obſerved, the Plants will have acquired Strength enough to be tranſplanted by the *Michaelmas* following; at which Time you muſt prepare a Bed of freſh Earth in the Flower-nurſery, into which you ſhould plant the Roots, at about ſix Inches Diſtance every Way; obſerving to plant them ſo low, as that the Top of the Roots may be three or four Inches under the Surface of the Bed; in this Bed they may remain one Year, during which Time they ſhould be frequently refreſhed with Water in dry Weather, and muſt be kept very clear from Weeds. In this Time the Roots will have acquired Strength enough to produce Flowers the following Year, ſo ſhould at *Michaelmas*, when their Leaves are decayed, be carefully taken up, and tranſplanted into the Flower-garden, obſerving to place them in the middle of the Borders, amongſt other hardy Kinds of Flowers, where being properly intermixed, they will make an agreeable Variety, and continue a long Time in Flower.

Theſe Plants may alſo be propagated by parting of their Roots, but this muſt not be too often repeated, leſt it weaken the Roots, and prevent their Flowering ſo ſtrong as they otherwiſe would do. Once in three Years will be often enough to tranſplant the Roots, at which Times you may ſeparate thoſe which are grown large, ſo as to make two or three Roots of each; but do not part them too ſmall, for that will ſo weaken them, as to prevent their flowering the following Summer. The beſt Time to tranſplant theſe Roots is at *Michaelmas*, juſt when their Leaves begin to decay.

ASPLENIUM, *or* Ceterach, [is ſo call'd of *Splen*, the *Spleen*, becauſe good againſt Diſeaſes of the Spleen; it is alſo call'd *Scolopendria*, becauſe the Leaves of this Plant, by their Figure, reſemble the Body and Feet of this Animal. The Name *Ceterach* is *Arabic*] Spleen-wort *or* Miltwaſte.

The *Characters* are;

The Leaves are like thoſe of the Polypody, *but leſs, and pretty round, notched toward the Side, downy, having a ſquamous Duſt, in which, by the Help of a Microſcope, membranous* [Capſulæ] *or Seed-pods lying cloſe to one another, are perceived, every one furniſhed with a little round Rope, which by its Conſtruction opening the Fruit into two Parts, pours forth certain very ſmall Seeds; the Root is fibrous. This Plant thrives in ſtony Places, as in Walls,* &c.

This Plant is of the Fern-kind, and grows upon old moiſt ſhady Walls in divers Parts of *England.*

ASTER, [ʼΑςὴρ, *Gr.* a Star; ſo call'd, becauſe the Flower is radiated with little Leaves after the manner of a Star, according to *Dioſcorides*: It is alſo called *Helenium*, of ἥλιος, the Sun; or, as others ſay, of *Helena*, the Daughter-in-law of *Priamus*] Starwort.

The *Characters* are;

It hath a fibroſe Root; the Leaves are, for the moſt part, intire, and are placed alternately on the Branches; the Stalks are branched; the Flowers are radiated, ſpecious, and have a ſcaly Cup: the Seeds are included in a downy Subſtance.

The *Species* are;

1. ASTER *Atticus, cœruleus, vulgaris. C. B.* The *Italian* blue Starwort.

2. ASTER *Pyrenaicus, præcox, flore cæruleo majore. Dod.* The early *Pyrenean* Starwort, with large blue Flowers.

3. ASTER *Novæ Angliæ, altiſſimus hirſutus, floribus maximis purpureo-violaceis. Par. Bat. Prod.* The tall rough *New England* Starwort, with large purple Flowers.

4. ASTER *Novæ Angliæ, latifolius, paniculatus, floribus ſaturate violaceis. H. L.* The broad-leaved panicled *New England* Starwort, with deep violet-colour'd Flowers.

5. ASTER *Novæ Angliæ, umbellatus, floribus dilute violaceis. H. L.* *New England* Starwort, with pale violet-colour'd Flowers growing in an Umbel.

6. ASTER *Virginianus, ſerotinus, parvo albente flore. Park.* The late-flowering *Virginian* Starwort, with ſmall whitiſh Flowers.

7. ASTER *cæruleus, ſerotinus, fruticeſcens, Tradeſcanti. Raii Hiſt.* *Tradeſcant*'s ſhrubby late-flowering blue Starwort.

8. ASTER *Tripolii flore. C. B.* Narrow-leav'd Starwort, with Flowers like *Tripolium.*

9. ASTER *Virginianus, pyramidatus, Hyſſopi foliis, aſperis, calycis ſquamulis foliaceis. Rand.* The *Virginian* Starwort, with Leaves like *Hyſſop*, and large blue Flowers with ſcaly Cups.

10. ASTER *Novæ Angliæ, linariæ folio, chamæmeli flore. Par. Bat.* *New England* Starwort, with Toad-flax Leaves, and Flowers like thoſe of Camomil.

11. ASTER *Americanus, Belvideræ foliis, floribus ex cæruleo albicantibus, ſpicis prælongis. Pluk. Phyt. Tab.* 78. *f.* 5. *American* Starwort, with Leaves like the *Belvidere*, and long Spikes of bluiſh white Flowers.

12. ASTER *ſerotinus ramoſus alter, flore purpuraſcente. H. R. Pur.* Another late-branch'd Starwort, with a purpliſh Flower.

13. ASTER *latifolius, tripolii flore. H. R. Par.* Broad-leav'd Starwort, with a Flower of *Tripolium.*

14. ASTER *tripolii flore, anguſtiſſimo & tenuiſſimo folio. Flor. Bat.* Starwort, with a *Tripolium* Flower, and very narrow ſlender Leaves.

15. ASTER *Canadenſis ſubhirſutus, ſalicis folio, ſerotinus, flore cæruleo. Inſt. R. H.* Late hairy *Canady* Starwort, with Willow Leaves, and a blue Flower.

16. ASTER *Atticus cæruleus minor. Inſt. R. H.* Small blue *Attick* Starwort.

17. ASTER *hirſutus Auſtriacus, cæruleo magno flore, foliis ſubrotundis. C. B. P.* Hairy *Auſtrian* Starwort, with a large blue Flower, and roundiſh Leaves.

18. ASTER *montanus cæruleus, magno flore, foliis oblongis. C. B. P.* Blue Mountain Starwort, with a large Flower, and oblong Leaves.

19. ASTER *Alpinus, flore purpuraſcente. Raii Hiſt.* *Alpine* Starwort, with a purpliſh Flower.

20. ASTER *Atticus Alpinus alter. C. B. P.* Another *Attick* Starwort of the *Alps.*

21. ASTER *Atticus cæruleus major. Inſt. R. H.* Greater blue *Attick* Starwort.

22. ASTER *maritimus paluſtris cæruleus, ſalicis folio. Inſt. R. H.* Marſh or Sea Starwort, with Willow Leaves, commonly called *Tripolium.*

23. ASTER *Canadenſis, foliis imis amplioribus cordatis & ſerratis. D. Sarrazin.* *Canady* Starwort, whoſe under-Leaves are broad, Heart-ſhaped, and ſerrated.

24. ASTER *virgæ aureæ latifoliæ folio ſubhirſuto, floribus fere umbellatis. D. Sarrazin.* Hairy Starwort, with broad Golden-rod Leaves, and Flowers growing almoſt in an Umbel.

25. ASTER *cæruleus ex* PROVINCIA MARIANA, *quaſi perfoliatus floribus ſparſis ſpicatis. Pluk. Mantiſ.* Blue Starwort from *Maryland*, whoſe Leaves almoſt ſurround the Stalk, and ſmall Flowers growing in Spikes.

26. ASTER *annuus, caule villoſo purpuraſcente, eryngii folio, flore maximo purpureo pulcherrimo, ſemine violaceo, Kiang-ſita Sinenſis. Jeſſieu.* Annual Starwort from *China*, with purple hairy Stalks, Eryngo Leaves, a beautiful large purple Flower, and a Violet-colour'd Seed.

27. ASTER *annnus, caule villoſo vireſcente, eryngii folio, flore maximo albo.* Annual Starwort from *China*, with hairy greeniſh Stalks, Eryngo Leaves, and a large white Flower.

28. ASTER *Americanus, foliis pinnatis & ſerratis, floribus aurantiis. Houſt.* *American* Starwort, with winged ſerrated Leaves, and Orange-colour'd Flowers.

29. ASTER *Americanus paluſtris, ſalicis folio ſerrato, floribus exiguis albidis. Houſt.* Marſh *American* Starwort, with a ſerrated Willow Leaf, and ſmall white Flowers.

30. ASTER *Americanus procumbens, bellidis minoris facie, Houſt.* Trailing *American* Starwort, with the Face of the leſſer Daizy.

31. ASTER *Africanus fruteſcens, lavendulæ folio, flore purpureo. Hort. Amſt.* Shrubby *African* Starwort, with a Lavender Leaf, and a purple Flower.

32. ASTER *Africanus ramoſus, hyſſopi foliis, floribus cæruleis. Olden. Inſt. R. H.* *African* branched Starwort, with Hyſſop Leaves, and blue Flowers.

33. ASTER *Americanus fruteſcens, ſatureiæ foliis ſcabris, floribus amplis ſaturate violaceis. Pluk. Alm.* Shrubby *American* Starwort, with rough Savory Leaves, and large Violet-colour'd Flowers.

The firſt, ſecond, eighth, and ninth Sorts are much preferable to the reſt, for ſmall Gardens, being not ſo apt to ſpread at the Root as are the others, and grow much lower, are leſs ſubject to ſhed their Seeds, and, with a ſmall Support, may be kept upright in a regular Shape. The ſecond Sort is the firſt in Flower; it grows about two Feet high, and produces large purple Flowers, but ſeldom in ſuch large Tufts as the firſt, nor are the Flowers ſo beautiful; however, as it comes to flower much ſooner, it deſerves a Place in every good Garden: This Sort is ſucceeded in Flower by the eighth, which is of ſhorter Growth, ſeldom riſing above a Foot in Height: The Flowers are much ſmaller, but are produced in very large Cluſters, ſo as to make a very agreeable Shew.

The firſt Sort ſucceeds theſe, and is one the moſt beautiful Kinds; it grows ſeldom more than two Feet high, and is eaſily kept in Compaſs; the Flowers are large, produced in great Tufts, and are of a fine blue Colour, with a yellow Thrum in the Middle, and is a great Ornament to Gardens in its Seaſon of Flowering. This is the *Amellus* of *Virgil.*

The third, fourth, and fifth Sorts, grow to the Height of four or five Feet, and produce large Quantities of Flowers, and are very proper for large Gardens, where they may have Room; but in ſmall Places they are very apt to over-run whatever is planted near them, and the Seeds are ſubject to ſhatter and fill the Garden with young Plants, if the Stalks are not cut down and carried away ſoon after the Flowers are paſt; for which Reaſons few People care to keep them, but yet in large Wilderneſſes they are very good to fill up Vacancies, and the Flowers are very proper to adorn Halls and Chimnies, and as they come at a Seaſon when few better Flowers appear, are the more valuable: But in order to keep them within Bounds, you ſhould at leaſt once a Year dig round them, and cut off all the ſpreading Roots, which would otherwiſe extend themſelves very far, and become unſightly, and with theſe Roots you may make freſh Plantations. Theſe come at a middle Seaſon to flower.

The ſixth, ſeventh, and ninth Sorts are very late Flowerers, ſeldom appearing till *October*, and do in a good Seaſon hold till the Middle of *November*; for which Reaſon they are much eſteem'd.

The ſeventh Sort grows to a great Height, and is very proper to intermix with other large Kinds; but it is not ſo ſubject to creep at the Root as they are, and the Flowers are large, growing in handſome Tufts.

The ſixth Sort flowers very late, but they are very ſmall, and grow ſparſedly on the Branches; for which Reaſon it is not ſo valuable as the other. But the ninth Sort is one of the moſt beautiful; the Flowers are large, and of a deep blue Colour; the whole Plant grows erect, and never creeps at the Root: It begins to flower toward the End of *September*, and continues till the Middle of *November*, and makes a very good Shew during that Seaſon.

The tenth Sort is a very handſome Plant, and is not ſo apt to ſpread as moſt of the other Kinds. This produces a great Quantity of white Flowers in *October*, and is worthy of a Place in every good Garden.

The eleventh Sort is apt to ſpread much by its creeping Roots, ſo ſhould not be placed amongſt other Plants, leſt it over-bear them. This continues flowering moſt part of *November.*

All the Sorts of *Starworts* are propagated by parting their Roots early in the Spring, and will grow in almoſt any Soil or Situation; the larger Sorts increaſe ſo faſt, that in a ſhort Time they will run over a large Spot of Ground, if not prevented: Theſe grow beſt in the Shade; the lower Kinds ſeldom creep at the Root, but muſt be taken up and planted every other Year, which will cauſe their Flowers to be the fairer. The ninth Sort may be increas'd by planting Cuttings of it in any of the Spring Months, which will flower the firſt Year: The Roots of this increaſing but ſlowly, this is the only Method to get a Stock of this Plant. This Plant, if ſet in Pots, and ſhelter'd in bad Weather, will continue flowering moſt part of the Winter, but dies to the Surface in the Spring, as do all the Sorts of *Starworts.*

The twenty-five Sorts firſt mentioned, are all of them very hardy Plants, which will endure the ſevereſt Cold of our Climate in the full Ground. Theſe are propagated by parting of their Roots, early in the Spring, before they begin to ſhoot; for, as many of the Sorts do not flower till late in the Autumn, ſo it will not be proper to tranſplant them after their Stems decay, which is ſeldom long before *Chriſtmas*, therefore it is better to be done in *February*.

The Seeds of the twenty-ſixth Sort were ſent from *China* to *Paris*, and ſown in the Royal Garden there, whence this Plant hath been diſtributed to ſeveral curious Gardens in *Europe*, and is become one of the greateſt Ornaments of the Flower-garden in Autumn. It begins to produce its Flowers the Beginning of *Auguſt*, and continues to produce new Flowers, until the Froſt prevents it.

This Plant is propagated from Seed, which ſhould be ſown on a warm Border ſoon after it is ripe (for if it be kept 'till Spring, it ſeldom grows.) The Plants will begin to appear early in the Spring, when they ſhould be clear'd from Weeds, and in very dry Weather muſt be refreſh'd with Water, which will forward their Growth; for during the firſt ſix Weeks or two Months after they come up, they make but ſmall Progreſs. The Beginning of *May* theſe Plants will be fit to tranſplant, when they ſhould be carefully drawn up, and planted in a Bed of rich Earth, ſix Inches aſunder, obſerving to water them frequently in dry Weather, and to keep 'em conſtantly clear from Weeds. When theſe Plants are about four or five Inches high, they ſhould be taken up with a Ball of Earth to their Roots, and tranſplanted, either into Pots, or into the Borders of the Flower-garden, where they are to remain, obſerving to water and ſhade them until they have taken Root; after which time thoſe in the Borders will require no farther Care, but to keep them clear from Weeds; but thoſe in the Pots muſt be frequently refreſh'd with Water, otherwiſe they will not grow large, nor produce near ſo many Flowers. In *Auguſt* theſe Plants will produce their beautiful Flowers, which will continue 'till the End of *September*; at which time the Seeds will ripen, when (as was before directed) ſome of it ſhould be ſown on a warm Border; but it will be proper to ſave ſome of the Seed 'till Spring, leſt, by a violent hard Winter, thoſe ſown in Autumn ſhould be deſtroyed.

The twenty-ſeventh Sort is a Variety of the twenty-ſixth, which accidently roſe from the ſame Seeds. This only differs from the former in the Colour of its Stalks and Flowers, which are white, ſo are not near ſo beautiful as the former, but for Variety a few of them may have Place in the Flower-garden.

This Plant is commonly called *Margarit*, by the *French* Gardeners.

The twenty-eighth, twenty-ninth, and thirtieth Sorts, were diſcovered by the late Dr. *William Houſtoun*, near *Vera-cruz* in the *Spaniſh Weſt-Indies*. The twenty-eighth and thirtieth grows plentifully on the ſandy Ground about *Old Vera-cruz*; and the twenty-ninth, in watery Places near the Sea. Theſe are all of them annual Plants, which may be propagated by ſowing their Seeds in Pots filled with light freſh Earth, early in the Spring; and then plunge the Pots into a Hot-bed of Tanners-bark, obſerving to water them frequently, as the Earth in the Pots ſhall require it; and in very hot Weather you ſhould ſhade the Glaſſes of the Hot-bed, during the Heat of the Day, to prevent the Earth from drying too faſt. When the Plants are come up, they muſt be frequently refreſhed with Water, and the Glaſſes of the Hot-bed ſhould be raiſed with Stones in the Heat of the Day, to admit Air to the Plants, otherwiſe they will draw up very weak. When the Plants are about an Inch high, they ſhould be carefully tranſplanted each into a ſeparate Pot, filled with light freſh Earth, and then plunged into the Hot-bed again, obſerving to ſhade the Glaſſes until they have taken new Root; after which time they ſhould have freſh Air admitted to them, by raiſing of the Glaſſes every Day, when the Weather will permit; you muſt alſo conſtantly ſupply them with Water, as you find the Earth in the Pots is dried. When the Plants have filled theſe Pots with their Roots, you muſt ſhift them carefully into Pots of a larger Size; and then plunge them into the Bark-bed in the Stove, where they will flower in *Auguſt*, and their Seeds will be perfected in *September*; after which the Plants decay.

The thirty-firſt, thirty-ſecond and thirty-third Sorts, are abiding Plants, which grow to the Height of ſix or eight Feet, and become ſhrubby. Theſe Plants may be propagated by Cuttings, which ſhould be taken off in *June*, and planted into Pots filled with light freſh Earth, and plunged into a moderate Hot-bed, obſerving to water and ſhade them until they have taken Root; after which time they ſhould be inured to bear the open Air by degrees. Towards the End of *July* they ſhould be taken out of the Hot-bed, and placed amongſt other exotick Plants, in a Situation where they may be defended from cold Winds; in this Place they may remain until the Beginning of *October*, when they ſhould be removed into the Green-houſe, obſerving to place them where they may enjoy a large ſhare of Air in mild Weather; otherwiſe their Shoots will become weak, and they will not produce their Flowers ſtrong, where their Shoots are too much drawn. Theſe Plants muſt be removed out of the Green-houſe in the Spring, at the time when Orange Trees are taken out, and ſhould be houſed again about the ſame time as thoſe are. In Winter they ſhould be frequently watered, but it muſt not be given them in large Quantities at that Seaſon. In Summer they muſt be plentifully watered in dry Weather, which will cauſe them to flower very ſtrong.

Theſe produce their Flowers in Autumn, and continue in Beauty a long time; during which Seaſon they afford an agreeable Proſpect, and greatly add to the Variety, amongſt other exotick Plants.

ASTERISCUS; [of *Aſter* or *Starwort*, which it is very like, except that the Seeds are not Pappous, but Channel'd.] Yellow Starwort.

This Plant having no *Engliſh* Name, I have call'd it *Yellow Starwort*, altho' it is very different in its *Characters* from that Plant; the Seeds of this being plain, and for the moſt part bordered round the Edges, having no Down adhering to them, and the Flowers being ſurrounded with a *Foliaceous Calyx*.

There are ſeveral *Species* of this Plant cultivated in the curious Botanick Gardens, but in *England* we have but three Sorts, which are preſerv'd for their Beauty, *viz.*

1. ASTERISCUS *annuus, foliis ad florem rigidis. Tourn.* The annual *Aſteriſcus*, with ſtiff Leaves and Flowers.

2. ASTERISCUS *annuus, Luſitanicus, odoratus. Boerh.* The *Portugal* ſweet-ſmelling annual *Aſteriſcus*.

3. ASTERISCUS *maritimus perennis patulus. Tourn.* The maritime Perennial dwarf *Aſteriſcus*.

The two firſt Sorts being Annuals, muſt be ſown in good Ground, and a warm open Situation, early in the Spring, in the Places where they are to remain, for they do not care for tranſplanting.

Theſe produce their Flowers in *Auguſt*, and if the Autumn is dry and warm, will perfect their Seeds in *September*, but in bad Years they often miſcarry.

The ſureſt Method to preſerve theſe Kinds, is, to ſow their Seeds in Autumn, on a dry Soil, and in a warm Situation, where the Plants will live thro' the Winter, and in the Spring they may be carefully removed, and planted where they are to flower. By this Method they will flower early in Summer, and produce very good Seeds.

The firſt Sort will grow near three Feet high, when planted in a good Soil, and will branch out and produce great Numbers of Flowers for upward of two Months; but the ſecond Sort is of humble Growth, and rarely riſes above a Foot high. This branches very much, and continues a long time in Flower.

The third Sort is propagated either from Seeds, or by planting Cuttings in any of the Summer Months; it is an abiding Plant, and continues flowering the greateſt Part of the Year, for which it is valued: This is tender, requiring a little Shelter in very hard Weather.

ASTEROIDES; Baſtard Starwort.

The *Characters* are;

It hath a compound radiated Flower, whoſe Disk is compoſed of many Florets which are hermaphrodite, and of Semi-florets which are female, and reſt upon the Embryo's, which are all included in a ſcaly Empalement. Theſe Embryo's afterwards become Seed, for the moſt part oblong.

The *Species* are;

1. ASTEROIDES *Alpina, ſalicis folio. Tourn. Cor.* Baſtard Starwort of the *Alps*, with a Willow Leaf.

2. ASTEROIDES *orientalis, petaſitidis folio, flore maximo. Tourn. Cor.* Oriental Baſtard Starwort, with a Butter-bur Leaf, and a large Flower.

3. ASTEROIDES *Americana minor annua. Vaill.* Leſſer *American* Baſtard annual Starwort.

The firſt of theſe Plants is pretty common in the *Engliſh* Gardens. This is a very hardy Plant, which is propagated by parting its Roots, (for it ſeldom produces good Seed in this Country); the beſt time to part the Roots is in *October*, about which time their Leaves decay. For if it be deferred till the Spring, and the following Seaſon ſhould prove dry, they will not flower ſo ſtrong as thoſe which were planted in Autumn, tho' they ſhould be conſtantly ſupplied with Water.

This Plant will thrive in almoſt any Soil or Situation, and continues to flower from *June* to *September*, which renders it worthy of a Place in every good Garden. This Plant is proper for large Borders, or to place under Groves of Trees, where if it be not too much ſhaded by the Trees, it will thrive very well, and add to the Variety. The Flowers are of a bright yellow Colour, and their Stems are about two Feet high, a great Number of which are produced from each Root, if they have ſufficient Strength.

The ſecond Sort was diſcovered by Dr. *Tournefort* in the *Levant*, and is at preſent rarely to be found in *England*. This may be propapated as the former Sort, but muſt have a warmer Situation; nor will it grow under the Drip of Trees. Theſe Plants ſhould not be tranſplanted oftener than every other Year, for when they are often parted and tranſplanted, they do not flower ſo well, nor make ſo large an increaſe.

The third Sort is an annual Plant, which muſt be raiſed on a Hot-bed, and planted into Pots filled with light rich Earth, and brought forward on another Hot-bed, obſerving not to draw them up too weak; and in *June* they ſhould be inured to bear the open Air by degrees, into which they ſhould be removed toward the End of the Month, and placed in a warm Situation, where they will flower in *July*, and their Seed will be perfected in *September*, ſoon after which time the Plants will decay.

ASTRAGALOIDES; Baſtard Milk-Vetch.

The *Characters* are;

It hath a papilionaceous Flower, out of whoſe Empalement riſes the Pointal, which afterwards becomes a Pod, ſhaped almoſt like a Boat, and full of Kidney-ſhap'd Seeds.

We have but one Sort of this Plant, which is;

Astragaloides *Luſitanica. Inſt. R. H.* Portugal Baſtard Milk-Vetch.

This Plant is only propagated by Seeds, which ſhould be ſown in the Place where it is to remain; for this Plant has a long tap Root, which runs deep into the Ground, ſo that it is very difficult to tranſplant, ſo as to thrive well, eſpecially if it be not done while the Plants are young; for I have ſeen Roots of this Plant, which have been four Feet long, and as large as a Man's Wriſt. The Seeds of this Plant ſhould be ſown in *March*, on a Border of light freſh Earth; and when the Plants are come up, they ſhould be thinned, where they grow too cloſe to each other, and muſt be carefully weeded; for if they are not kept very clean while they are young, the Weeds will ſoon over-bear and deſtroy them. Theſe Plants will require no other Culture, but only to dig about their Roots every Spring, juſt before they begin to ſhoot, being careful not to bruiſe or injure their Roots, and to make the Earth looſe about them. In Summer they muſt be kept clear from Weeds; with this Management the Plants will thrive very well, but they will not flower until the third Year after ſowing, but will continue to flower every Year after. The Stems of this Plant do uſually riſe three Feet high, the Flowers are produced in a long Spike, which are ſhaped like thoſe of the *Lupine*, and come out on Branches, from the Wings of the Leaves, all the way up the Stalks. The Flowers appear firſt white, before they are fully blown out; afterwards they are of a dark yellow Colour, and continue near a Month before they fall off. This Plant rarely produces good Seeds in *England*, ſo that it muſt be procured from Abroad.

ASTRAGALUS; Milk-Vetch.

The *Characters* are;

It hath a papilionaceous Flower, conſiſting of the Standard, the Keel, and the Wings. Out of the Flower-cup ariſes the Pointal, covered with a Sheath, which afterward becomes a bicapſular Pod, which is filled with Kidney-ſhap'd Seeds; to which Notes may be added, that the Leaves grow by Pairs along the middle Rib, with an odd one at the End.

The *Species* are;

1. Astragalus *luteus perennis procumbens vulgaris ſive ſylveſtris. Mor. Hiſt.* Wild Liquorice or Liquorice-Vetch.

2. Astragalus *luteus annuus Monſpeliacus procumbens. Mor. Hiſt.* Yellow annual trailing Milk-Vetch of *Montpelier*.

3. Astragalus *luteus perennis, ſiliqua gemella rotunda veſicam referente. Mor.* Yellow perennial Milk-Vetch, with a round Pod reſembling a Bladder.

4. Astragalus *annuus maritimus procumbens latifolius, floribus pediculo inſidentibus. Tourn.* Annual maritime trailing Milk-Vetch, with broad Leaves, and the Flowers ſitting on Pedicles.

5. Astragalus *annuus anguſtifolius, floſculis pediculis oblongis inſidentibus. Tourn.* Narrow-leav'd annual Milk-Vetch, whoſe Flowers ſtand on long Foot-ſtalks.

6. Astragalus *annuus anguſtifolius, floſculis ſubcœruleis, cauliculis adhærentibus. Tourn.* Narrow-leav'd annual Milk-Vetch, with blueiſh Flowers, adhering to the Stalks.

7. Astragalus *annuus procumbens, floribus glomeratis purpureis. Boerh. Ind.* Annual trailing Milk-Vetch, with purple Flowers growing in Cluſters.

8. Astragalus *Alpinus procerior alopecuroides. Tourn.* Taller Fox-tail Milk-Vetch of the *Alps*.

9. Astragalus *pumilis, ſiliqua epiglottidis forma. Tourn.* Dwarf Milk-Vetch, with a Pod ſhaped like the Epiglottis.

10. Astragalus *montanus purpureus Anglicus. Tourn.* *Engliſh* purple Milk-Vetch of the Mountains.

11. Astragalus *Alpinus, tragacanthæ folio, veſicarius. Tourn.* Bladder Milk-Vetch of the *Alps*, with a Goat's-Thorn Leaf.

12. Astragalus *Alpinus, tragacanthæ folio, ramoſus, flore cœruleo glomerato. Tourn.* Branched Milk-Vetch of the *Alps*, with a Goat's-Thorn Leaf, and blue glomerated Flowers.

13. Astragalus *orientalis altiſſimus, galegæ foliis amplioribus, flore parvo flaveſcente. Tourn. Cor.* Talleſt Eaſtern Milk-Vetch, with ample Goat's-rue Leaves, and a ſmall yellowiſh Flower.

14. Astragalus *orientalis altiſſimus, fraxini folio, flore è viridi flaveſcente. Tourn. Cor.* Talleſt Eaſtern Milk-Vetch, with an Aſh Leaf, and a greeniſh yellow Flower.

15. Astragalus *orientalis maximus incanus erectus, caule ab imo ad ſummum florido. Tourn. Cor.* Greateſt hoary upright Milk-Vetch, with a Stalk flowering from the Bottom to the Top.

16. Astragalus *Canadenſis, flore viridi flaveſcente. Acad. Reg. Scien.* Milk-Vetch of *Canady*, with a greeniſh yellow Flower.

The firſt Sort is very common in divers Parts of *England*, and is ſeldom preſerved in Gardens. This dies to the Root every Winter, and riſes again the following Spring. It flowers in *June*, and the Seeds are ripe in *Auguſt*. This may be propagated by ſowing the Seeds in the Spring, upon almoſt any Soil, or in any Situation, and requires no farther Care but to keep it clear from Weeds.

The tenth Sort grows wild in ſeveral Parts of *England*, but is not ſo common as the former. This may be propagated in the ſame manner as the former.

The ſecond, fourth, fifth, ſixth and ſeventh Sorts are annual Plants. Theſe may be propagated by ſowing of their Seeds in *March* upon a Bed of light freſh Earth, in an open Situation; and when the Plants are come up, they ſhould be thinn'd, leaving them about a Foot aſunder; after this there will be no other Trouble but to keep 'em clear from Weeds. Theſe will produce their Flowers in Summer, and in Autumn their Seeds will be perfected.

The other Sorts are all abiding Plants, but muſt be propapated by ſowing of their Seeds towards the latter End of *March*, on a Bed of freſh light Earth, obſerving not to bury the Seeds too deep, leſt they rot; and when the Plants are come up, they ſhould be thinned, leaving them about ſix Inches aſunder; and during the Summer following you ſhould conſtantly keep 'em clear from Weeds. In *October* you may tranſplant theſe Plants into the Borders where they are to remain, in doing of which you ſhould be careful to dig to the Bottom of their Roots; for moſt of them ſend forth long tap Roots; which go deep into the Earth, and, if cut or broken, rarely overcome it. Theſe Plants, many of them, grow very tall, and ſhould be allowed a great Share of Room. The fifteenth Sort is a beautiful Plant; it grows about four Feet high, and produces Flowers from the Bottom to the Top of the Stems, ſo that it makes a fine Appearance in a large Border. The ſixteenth Sort is ſomewhat tender, and is often deſtroyed in ſevere Froſt, but in mild Winters it will ſtand abroad very well.

ASTRANTIA; Maſterwort.

The *Characters* are;

It hath a roſe and umbellated Flower, conſiſting of ſeveral Leaves; the Apices are for the moſt part reflexed, and are placed orbicularly on the Flower-cup; this afterwards becomes a Fruit, compoſed of two Seeds, each of which is covered with a furrow'd Husk: to theſe Notes muſt be added, the Flowers are collected into a Head, ſurrounded with a Circle of Leaves.

The *Species* are;

1. ASTRANTIA *major, corona floris purpuraſcente. Tourn.* Black Maſterwort, with purpliſh Flowers.

2. ASTRANTIA *major, corona floris candida. Tourn.* Greater Maſterwort, with white Flowers.

Theſe Plants are both very hardy: They may be propagated either by ſowing of their Seeds, or parting their Roots. If they are propagated from Seeds, they ſhould be ſown early in the Spring, or in Autumn, ſoon after the Seeds are ripe, on a ſhady Border; and when the Plants are come up, they ſhould be carefully weeded, and where they are too cloſe, ſome of the Plants ſhould be drawn out, to allow Room for the others to grow, until *Michaelmas*, when they ſhould be tranſplanted where they are to remain; which ſhould always be in a moiſt Soil, and a ſhady Situation. The Diſtance theſe Plants ſhould be placed is two Feet, for their Roots will ſpread to a conſiderable Width, if they are permitted to remain ſome Years in the ſame Place. They require no other Culture, but to keep 'em clear from Weeds, and every third or fourth Year taken up at *Michaelmas*, and their Roots parted and planted again. Theſe Plants are ſeldom preſerved but in botanick Gardens, there being no great Beauty in their Flowers, nor are they uſed in Medicine at preſent; tho' by ſome Perſons they have been called *Black Hellebore*, and I believe have been uſed for that.

ATMOSPHERE; ['Ατμοσφαῖρα, of 'Ατμὸς, a Vapour, and σφαῖρα, *Gr.* a Sphere] is an Appendage of the Earth, which conſiſts of a thin, fluid, elaſtick Subſtance, call'd *Air*, ſurrounding the Terraqueous Globe to a conſiderable Height.

The whole Maſs or Aſſemblage of ambient Air, is commonly underſtood to be the *Atmoſphere*.

But the more accurate Writers reſtrain the Term *Atmoſphere* to that Part of the Air which is next to the Earth, which receives the Vapours and Exhalations, and which is terminated by the Refraction of the Light of the Sun.

Thoſe Spaces that are higher, and beyond theſe, are call'd *Æther*; and being ſuppos'd to be poſſeſs'd by a finer Subſtance, are call'd the *Ætherial Regions*, tho' theſe perhaps are not deſtitute of Air.

This *Atmoſphere* inſinuates itſelf into all the Vacuities of Bodies, and by that means becomes the great Spring of moſt of the Mutations here below, as Generation, Corruption, Diſſolution of Vegetables, *&c.* To the Preſſure of the *Atmoſphere* Plants owe their Vegetation, as well as Animals do their Reſpiration, Circulation, and Nutrition. See *Æther* and *Air*.

Dr. *Halley* found, by undoubted Experiments, that the Weight of *Mercury* to *Water*, is as $13\frac{1}{2}$ to 1, or very near it; and that the Specifick Weight of *Air* to *Water*, is as 1 to 800; ſo that the Weight of *Mercury* to *Air*, is as 10800 to 1; and a Cylinder of *Air* of 10800 Inches, or 900 Feet, is equal to an Inch of *Mercury*: ſo that if the *Air* was of an equal Denſity like *Water*, the whole *Atmoſphere* would be no more than $5\frac{1}{10}$ Miles high, and in the Aſcent of every 900 Feet, the *Barometer* would ſink an Inch; but the Expanſion of the *Air* increaſing in the ſame Proportion, as the incumbent Weight of the *Atmoſphere* decreaſes, that is, as the *Mercury* in the *Barometer* ſinks, the upper Parts of the *Air* are much more rarefied; and each Space anſwering to an Inch of *Quickſilver*, grows greater and greater, ſo that the *Atmoſphere* muſt be extended to a much greater Height.

Upon theſe and ſuch like Suppoſitions, it will appear, that at the Height of 45 Miles, the *Air* is ſo rarified, as to take up 3000 Times the Space it occupies here; and at 53 Miles high it would be expanded above 300000 Times: But it is probable, that the utmoſt Power of its Spring cannot exert itſelf to ſo great an Extenſion, and that no Part of the *Atmoſphere* reaches above 45 Miles from the Surface of the Earth.

ATRACTYLIS. Diſtaff-Thiſtle; *vide* CNICUS.

ATRIPLEX; Orrach.

The *Characters* are;

It hath no Leaves to the Flower, but conſiſts of many Stamina, which ariſe from a five-leav'd Empalement; the Pointal afterwards becomes the Seed, which is flat and orbicular, and is incloſed in the Empalement, which becomes a foliaceous Capſule, in which are included two Sorts of Seeds.

The *Species* are;

1. ATRIPLEX *hortenſis alba, ſive pallide virens. C. B. P.* Garden Orrach, of a pale green Colour.

2. ATRIPLEX *hortenſis nigricans. C. B. P.* Dark green Garden Orrach.

3. ATRIPLEX *hortenſis rubra. C. B. P.* Red Garden Orrach.

4. ATRIPLEX *latifolia, ſive Halimus fruticoſus. Mor. Hiſt.* Shrubby broad-leav'd Orrach, commonly called *Sea-purſlane-tree.*

5. ATRIPLEX *maritima fruticoſa, Halimus & Portulaca marina dicta, anguſtifolia. Raii Syn.* Shrubby Sea Orrach, commonly called *Sea-purſlane*, with a narrow Leaf.

6. ATRIPLEX *maritima laciniata. C. B. P.* Sea Orrach, with jagged Leaves.

7. ATRIPLEX *anguſto oblongo folio. C. B. P.* Long narrow-leav'd Orrach.

8. ATRIPLEX *anguſtiſſimo & longiſſimo folio. H. L.* Orrach, with very long narrow Leaves.

9. ATRIPLEX *ſylveſtris, fructu compreſſo roſeo & ſtellato. C. B. Prod.* Wild Orrach, with a compreſſed ſtarry and roſe-ſhap'd Fruit.

10. ATRIPLEX *Cretica maritima erecta, folio triangulari. Tourn. Cor.* Upright Sea *Candy* Orrach, with a triangular Leaf.

11. ATRIPLEX *Græca fruticoſa humifuſa, halimi folio. Tourn. Cor.* Dwarf ſhrubby Orrach, with a Sea-purſlane Leaf.

12. ATRIPLEX *orientalis fruteſcens, folio ampliſſimo argenteo. Tourn. Cor.* Shrubby Oriental Orrach, with a large Silver-colour'd Leaf.

13. ATRIPLEX *orientalis, frutex aculeatus, flore pulchro. Tourn. Cor.* Shrubby prickly Oriental Orrach, with a fair Flower.

The firſt of theſe Plants was formerly cultivated in the Kitchen-Gardens, as a culinary Herb, being uſed as Spinage, and is by ſome Perſons preferred to it, tho' in general it is not eſteemed amongſt the *Engliſh*; but the *French* now cultivate this Plant for Uſe. It may be ſown in the Spring as Spinage, and muſt be eaten young; for when it is run up to Seed, it is very ſtrong: This Plant, if ſuffer'd to ſhatter its Seeds in a Garden, will become a laſting Inhabitant, the Seeds often remaining ſeveral Years in the Ground, and every Time the Ground is dug, will ſend forth many of the Plants.

The ſecond and third Sorts are believed to be Varieties of the firſt, for they differ in nothing from that, but in the Colour of their Stalks and Leaves; however, this Difference is not accidental, for I have ſeveral Years cultivated all the three Sorts in the ſame Soil, and they have always retained their Difference from Seeds, and have not interchanged, as moſt Varieties generally do.

Theſe Plants are annual, ſo muſt be ſown for Uſe early in the Spring, or at *Michaelmas*, ſoon after the Seeds are ripe; at which Time it generally ſucceeds better than when it is ſown in the Spring, and will be fit for Uſe at leaſt a Month earlier in the Spring. Theſe Plants require no other Culture, but to hough them when they are about an Inch high, to cut them down where they are too thick, leaving them about four Inches aſunder, and to cut down all the Weeds. This muſt be done in dry Weather, otherwiſe the Weeds will take Root again, and render your Work of no Uſe. When your Plants are grown about four Inches high, it will be proper to hough them a ſecond time, in order to clear them from Weeds; and if you obſerve the Plants are left too cloſe in any Part, you muſt then cut them out. If this be well perform'd, and in dry Weather, the Ground will remain clean until the Plant is fit for Uſe. Where theſe Plants are ſown on a rich Soil, and allowed a good Diſtance, the Leaves will be very large, in which the Goodneſs of the Herb conſiſts. This muſt be eaten while it is young, for when the Stalks become tough, it is good for nothing. Some few Plants of each Kind may be permitted to ſtand for Seed, to preſerve their Kinds, which will ripen in *Auguſt*, and may then be cut and laid on a Cloth to dry, after which the Seeds may be beaten out, and put up for Uſe. The firſt Sort is ordered by the College of Phyſicians for medicinal Uſe.

The fourth Sort was formerly cultivated in Gardens as a Shrub, and by ſome Perſons they were formed into Hedges, and conſtantly ſheer'd to keep them thick; but I do not approve of this Plant for ſuch Purpoſes, on many Accounts, for it is too vigorous; the Shoots, in one Month, at the growing Seaſon of the Year, will be two Feet long, provided they have a good Soil, ſo that a Hedge of this Plant cannot be kept in tolerable Order, nor will it ever form a thick Hedge. But a worſe Inconvenience attends this Plant, for in very hard Winters it is often deſtroyed, as alſo in very dry Summers many of the Plants will decay, whereby there will become large Gaps in the Hedge.

But altho' this Plant be not proper for Hedges, yet it may have a Place in Wilderneſs Quarters, where it will ſerve to thicken, and the Silver-coloured Leaves will add to the Variety, amongſt other Shrubs of the ſame Growth. This will grow eight or ten Feet high, and if ſuffered to grow wild without pruning, will ſpread ſeveral Feet in Compaſs, and will ſometimes produce Flowers.

It may be propagated by Cuttings, which may be planted in any of the Summer Months, on a ſhady Border, where, if they are duly watered, they will ſoon take Root, and will be fit to tranſplant the *Michaelmas* following, when they ſhould be planted where they are to remain; for they do not ſucceed well in tranſplanting, when they are grown pretty large and woody.

The fifth Sort grows wild in divers Parts of *England* on the Sea-ſide, from whence the Plants may be procured; or it may be propagated by Cuttings, in the ſame manner as the former Sort. This is a low Under-ſhrub, ſeldom riſing above two Feet and an half, or at moſt three Feet high; but becomes very buſhy. The Leaves of this Kind are narrow, and of a whitiſh Colour, but are not ſo white as thoſe of the former. This may have a Place amongſt other low Shrubs; and if planted on a poor gravelly Soil, will abide ſeveral Years, and make a pretty Diverſity.

The ſixth, ſeventh, eighth, and ninth Sorts grow wild in *England* and *Holland*, and are ſeldom preſerved but in botanick Gardens, for the ſake of Variety. Theſe are propagated by Seeds, which may be ſown ſoon after they are ripe, when they will ſucceed much better than if they are ſown in the Spring. When the Plants are come up, they ſhould be thinned, ſo as to leave them four or five Inches diſtant, and kept clear from Weeds, which is all the Culture they require.

The tenth, eleventh, twelfth, and thirteenth Sorts were diſcovered by Dr. *Tournefort* in the *Levant*, who ſent their Seeds to the Royal Garden at *Paris*, from whence they have been communicated to ſeveral Gardens in *Holland* and *England*. The tenth Sort may be propagated by Seeds as the four former Sorts, but muſt have a warmer Situation, otherwiſe it will not perfect Seeds in this Country.

The other three Sorts may be propagated by Seeds, or by Cuttings, planted on a ſhady Border, as was directed for the fourth and fifth Sorts. Theſe muſt be planted in Pots, and ſheltered in Winter under a Garden-frame, where they may have as much free Air as poſſible in mild Weather; but in hard Froſt they muſt be ſheltered, otherwiſe it will deſtroy them. Some of theſe Plants may be planted on a warm Border, in a poor gravelly Soil, where they will endure the Cold of our ordinary Winters very well, and will make a pretty Variety amongſt Plants of the ſame Growth. The eleventh Sort will ſeldom riſe above two Feet high, but the twelfth and thirteenth Sorts will grow to be ſix or ſeven Feet high.

AVENA; Oats.

The *Characters* are;

It is of the Graſs-leav'd Tribe; the Flowers have no Petals, and are diſpoſed in a looſe Panicle; the Grain is eatable.

The *Species* are;

1. AVENA *vulgaris ſeu alba. C. B. P.* Common or white Oats.
2. AVENA *nigra. C. B. P.* Black Oats.
3. AVENA *nuda. C. B. P.* Naked Oats.

The firſt Sort here mentioned is the moſt common in *England*; the ſecond Sort being much leſs eſteemed, the white being the heavier Grain, and makes whiter Meal. The third Sort is leſs common than either of the former, eſpecially in the Southern Parts of *England*; but in the North of *England*, *Scotland*, and *Wales*, it is cultivated in plenty. This Sort is eſteemed, becauſe the Grain threſhes clean out of the Huſk, and need not be carried to the Mill to be made into Oatmeal or Griſt. An Acre of Ground doth not yield ſo many Buſhels of theſe, as of the common Oats, by Reaſon the Grain is ſmall and naked, and goes near in Meaſure; but what is wanting in the Meaſure, is ſupplied in Value.

Oats are a very profitable Grain, and abſolutely neceſſary, being the principal Grain which Horſes love; and are eſteemed the moſt wholeſome Food for thoſe Cattle, being ſweet, and of an opening Nature; other Grains being apt to bind, which is injurious to labouring Horſes. But if you feed them with this Grain, ſoon after they are houſed, before they have ſweat in the Mowe, or are otherwiſe dried, it is as bad on the other hand; for they are then too laxative.

This Grain is a great Improvement to many Eſtates in the North of *England*, *Scotland*, and *Wales*; for it will thrive on cold barren Soils, which will produce no other Sort of Grain; it will alſo thrive on the hotteſt Land. In ſhort, there is no Soil too rich or too poor for it, too hot or too cold for it. And in wet Harveſts when other Grain is ſpoil'd, this will receive little or no Damage; the Straw and Huſks being of ſo dry a Nature, that if they are houſed wet, they will not heat in the Mowe, or become mouldy as other Grain uſually do, ſo is of great Advantage in the Northern Parts of *England*, and in *Scotland*, where their Harveſt is generally late, and the Autumns wet.

The Meal of this Grain makes tolerable good Bread, and is the common Food of the Country People in the *North*. In the *South* it is eſteemed for Pottage and other Meſſes, and in ſome Places they make Beer with this Grain.

The beſt time for ſowing of Oats is in *February* or *March*, according as the Seaſon is early or late, and ſometimes I have known it ſown in *April*, and has been early ripe. The Manner of preparing the Ground, as alſo of ſowing the Grain, being the ſame as for other Corn, I ſhall not mention it in this Place.

AVENUES, are Walks or Entrances leading to a Place, and in Gardening, are Walks planted with Rows of Trees, made in the Front-end of the Garden, leading to the Front of an Houſe, or to a Garden Gate, to a Highway Gate or Wood, to terminate in a Proſpect.

As to ſuch *Avenues* that lead to an Houſe, they ought to be as wide as the whole Breadth of the Front, and if they be wider, they are better.

And as for ſuch *Avenues* to Woods or Proſpects, *&c.* they ought not to be leſs than ſixty Feet in Breadth; and becauſe ſuch Walks are a long time before they are ſhady, it will be convenient to plant another Row on each Side, rather than to loſe the Statelineſs that the main Walk will afford in Time by being broad, where any thing of a Proſpect is to be gained.

And as to the Diſtance one from another, they ſhould not be planted nearer to one another than thirty-five or forty Feet, eſpecially if the Trees are any thing of a ſpreading Kind; and the ſame Diſtance, if they are for a regular Grove.

As to the Trees proper for planting *Avenues*, they may be the *Engliſh Elm*, the *Lime Tree*, the *Horſe Cheſnut*, the *Common Cheſnut*, the *Beech*, and the *Abele*.

The *Engliſh Elm* is approv'd for all Places where it will ſucceed, and that will do in moſt Places, except in very wet or cold ſhallow Grounds. 1. Becauſe it will bear cutting, heading, lopping in any manner whatſoever, and probably with better Succeſs than any other Tree.

Others approve of the *Dutch Elm*, rough or ſmooth; the broad-leav'd or *Witch Elm*, becauſe they are of quicker Growth than the *Engliſh*, and will grow tolerably well in almoſt any Soil: It will alſo remove very well, and ſeldom miſcarries, if but an ordinary Care be taken of it, which the *Engliſh Elm* is ſubject to do. 2. Becauſe it is out with green Leaves in the Spring, with the earlieſt Plants, and continues its Beauty as long as almoſt any other Tree. 3. Becauſe it makes an incomparable Hedge, and is preferable to all others for lofty Eſpaliers.

Secondly, The *Lime Tree:* This is approv'd by others, becauſe it will do well in any tolerable Soil, if the Bottom be not wet and cold, and becauſe of the regular Shape it has in growing, the Agreeableneſs of its Shade, and the beautiful Colour of its Leaves.

Thirdly, The *Horſe Cheſnut* is recommended to be uſed every where in ſuch Places as are very well defended from ſtrong Winds; becauſe where-ever it grows freely, if it be not ſkilfully manag'd now and then by cutting, the Branches are ſubject to ſplit down: This Tree is valuable on account of its quick Growth, the Earlineſs of its coming out, the Nobleneſs of its Leaves, and the Beauty of its Flowers, being a fine Plant both for Shade and Ornament. This delights in a ſtrong, hearty Soil, but will do well in any tolerable Soil, if good Care be taken in the Planting of it.

Fourthly, The *common Cheſnut* will do well in a proper Soil, and will riſe to a conſiderable Height if planted cloſe together, but if it be planted ſingly, where the Tree can take its own natural Shape, it is rather inclin'd to ſpread and grow globous than tall.

Fifthly, the *Beech* is recommended by ſome, but this ſeldom ſucceeds well after tranſplanting, without extraordinary Care, tho' it arrives to a very large Tree in many Places in *England* where it grows naturally, and is the moſt tedious and troubleſome to raiſe to any tolerable Size in a Nurſery Way.

Sixthly, the *Abele:* This indeed grows more diſpers'd and looſe in its Head than any of the former, and conſequently is worſe for Defence; but yet is not to be left out from the Number of Trees for *Avenues*, becauſe it is the quickeſt in Growth of all the Foreſt Trees, and will thrive tolerably well in almoſt any Soil, and particularly in wet Ground, where few of the before-mention'd Trees will thrive: And this ſeldom fails in tranſplanting.

Seventhly, The *Oak*; but this is ſeldom uſed in planting *Avenues*, becauſe it requires ſo long a time to raiſe it up to any tolerable Stature in the Nurſery Way; nor is it apt to thrive much after it has been tranſplanted, if at any Bigneſs.

As for the *Alder*, *Aſh*, *Platanus*, and *Sycamore*, they are but rarely uſed for planting *Avenues*.

The old Method of planting Avenues with regular Rows of Trees, is what has been generally practis'd 'till of late Years; ſince the old Manner of laying out Gardens being with good Reaſon diſuſed, they have lately introduced a more magnificent Method of planting Avenues; which is to plant the Trees in Clumps, or Platoons, making the Opening much wider than before, and ſo place the Clumps of Trees at about three hundred Feet Diſtance from each other. In each of theſe Clumps ſhould be planted ſeven or nine Trees, according to the Fancy of the Owner, or the Perſon who deſigns the Plantation: But this is only to be practis'd, where the Avenue is of a tolerable Length; for, in ſhort Walks, it will not appear ſo ſightly as even Rows of Trees. In large Parks this Method of planting in Clumps has a very good Effect; for as a Perſon rides through the Avenue, the Opening between the Trees, to the Turf where the Deer are feeding, is much more agreeable, than in paſſing between ſtrait Rows of Trees. The Trees ſhould be planted about thirty Feet aſunder in the Clumps, and a little Ditch thrown up round each Clump, to prevent the Deer from coming to bark them.

AUGUST.

Work to be done in the KITCHEN GARDEN.

The Beginning of this Month you muſt ſow Onions, to ſupply the Table early in the Spring for Sallets, *&c.* and leſt the Winter ſhould prove ſevere, it will be proper to ſow a few *Welſh* Onions at the ſame time; for theſe will endure the greateſt Cold, when the common Sort are all deſtroy'd; but they are ſtronger than the common Sort, which is the only Reaſon they are not ſo much eſteem'd.

You muſt alſo ſow Spinage to ſtand the Winter, to ſupply the Kitchen in Winter and Spring. The beſt Sort to endure Cold is the prickly Kind, which is what moſt People ſow at this Seaſon, it being much hardier than the round-leav'd Kinds.

About the fifth or ſixth Day of this Month you ſhould ſow your early *Batterſea* Cabbage-ſeed; for that which is ſown earlier will run to ſeed in the Spring, if the Winter ſhould prove mild: And if it is ſown later than this time, the Plants will not have Strength to reſiſt the Cold, nor will they come ſo early, provided they do ſtand thro' the Winter.

The tenth or eleventh Day of this Month you ſhould ſow ſome Cauliflower-ſeed for the early Crop to be planted under your Bell or Hand-glaſſes, and under the Walls where they are deſign'd to ſtand open: But you ſhould alſo ſow ſome more Seeds about the fourteenth Day for a ſecond Crop, to plant under Frames to abide the Winter; for it often happens, in a mild Winter, that many of thoſe Plants which were firſt ſown, do run in the Spring; therefore if you have not a ſecond Supply, you will be at a great Loſs; beſides, theſe will come to flower after the firſt ſowing is gone, ſo that your Table will be ſupply'd much longer with the ſecond ſowing.

About the middle of this Month you ſhould ſow ſome common Cabbage-Lettuce, and ſome brown *Dutch* Lettuce to ſtand the Winter on warm Borders without covering; and about the twentieth Day of the Month you may ſow ſome Sileſia, Cos, and other large Kinds of Lettuce, to plant under Glaſſes, or upon Beds, to be cover'd in Winter, that they may come early the following Spring: you ſhould always obſerve, if the Weather be hot and dry when all theſe Seeds are ſown, to ſhade the Beds with Mats in the Heat of the Day, and to ſupply them duly with Water, otherwiſe the Plants will not come up regularly.

In moiſt Weather tranſplant Endive and Celery for blanching, which ſhould be well water'd to ſettle the Earth to their Roots; and if the Weather ſhould alter to Drought, they muſt be duly water'd until they have taken Root.

You may now tranſplant ſome of the Lettuces which were ſown the former Month, to ſupply the Kitchen in Autumn; theſe ſhould be planted in a warm Situation, leſt the Froſts, which often happen early in *October*, ſhould injure them: They muſt alſo be duly water'd until they have taken Root.

Toward the latter End of the Month you ſhould ſow ſeveral Sorts of Seeds which remain a long Time in the Ground, which, if ſown in the Spring, do often miſcarry; as Chervil, Angelica, Lovage, Maſterwort, Scurvygraſs, Fennel, Alexanders, Sweet-Seſeli, and ſome others, which always ſucceed better when ſown at this Seaſon, than when they are ſown in the Spring.

Your Beds of Coleworts, *&c.* which were ſown the laſt Month, ſhould be carefully weeded; and if the Plants are very thick, ſome of them ſhould be drawn out, and tranſplanted into another Spot, that thoſe which remain may have more room to grow.

Cut off the flowering Branches of moſt Sorts of Aromatick Plants, as Lavender, Roſemary, Savory, Hyſſop, *&c.* that they may make new Shoots before Winter; but do not perform this Work in dry Weather, for many times the Plants are deſtroy'd by it, when there happens to be a long Drought.

Pull up Onions, Garlick, Rocambole, and Shallots, when their Leaves begin to wither and fall; and ſpread them thin in an airy Place to dry, before you put them up where they are to remain for Winter uſe.

In dry Weather you muſt earth up your Celery which is large enough, obſerving not to bury the Hearts of the Plants, for that will rot them. You muſt alſo tye up your Endive, which is full grown, to blanch; this muſt alſo be perform'd when the Leaves are very dry, otherwiſe the Plants will rot.

Your Artichokes which were planted the laſt Spring, will now begin to ſhew their Fruit; therefore all ſmall Suckers which come out on the Sides of their Stalks, ſhould be cut off; for if they are permitted to remain on, they will weaken and ſtarve the top Fruit: You ſhould alſo clear them from Weeds, or any other large growing Plants, which ſtand near them.

Tranſplant your Brocoli (which was not planted out the former Month) into the Place where it is to remain for flowering, obſerving to water it duly until it has taken Root. Theſe Plants ſhould be planted in Rows about two Feet aſunder, and a Foot Diſtance from each other in the Rows.

You may yet tranſplant ſome Savoys, to come late in the Spring; but if the Winter ſhould prove ſevere, they will not grow to be large, nor will they cabbage; but in mild Winters they often ſucceed very well.

Obſerve to keep the Roots of your Melons from too much Wet, which many times cauſes the Plants to decay before the Fruit is ripe.

Your Cucumbers for pickling are now in Seaſon, therefore they ſhould be looked over twice a Week, to gather ſuch as are fit, for in a ſhort time they will grow too large for that Purpoſe; theſe muſt alſo be frequently water'd in dry Weather, which will cauſe them to produce a greater Quantity of Fruit.

The Aſparagus which was planted the laſt Spring, ſhould be carefully clear'd from Weeds; for at this Seaſon it will make new Shoots, which will be much ſtronger, where they are not injur'd by Weeds or other Plants, than on the contrary.

All your Winter Crops, as Parſnips, Leeks, Beets, Cabbages, *&c.* ſhould be conſtantly kept clear from Weeds, which, if ſuffered to grow, will greatly injure your Crops, and will ſoon ſcatter their Seeds at this Seaſon, whereby your Ground will be plentifully ſtock'd with Weeds, which cannot be rooted out in many Years.

The Dunghills ſhould alſo be cleared from Weeds, particularly Atriplex's and Nightſhade, which at this Seaſon are very common upon almoſt every Dunghill, and if the Seeds are permitted to ſcatter, when the Dung is carried into the Garden, they will be mixed therewith, and thereby fill your Ground with Weeds; therefore they ſhould be pull'd up, and caſt into an Heap to rot at ſome Diſtance from the Garden or Dunghill; for if they are only hough'd down, and permitted to lie upon the Dunghill, (as is by ſome practiſed) the Seeds will ripen as they lie, and be almoſt as bad as if they had been ſuffered to grow to Maturity.

You may in this Month plant Slips of Sage, Roſemary, Stœchas, Lavender, Maſtick, and other Aromatick Plants, where it was omitted in the Spring; but theſe will not be near ſo ſtrong, nor capable of reſiſting the Cold ſo well, as thoſe planted in the Spring, and therefore ſhould be ſhelter'd, if the Winter ſhould prove ſevere.

Cut ſuch Herbs as are now in Flower to diſtil, or to dry for Winter Uſe, always obſerving to hang them up in a dry ſhady Place; for if they are dried in the Sun, the will ſhrink up, and be little worth.

Continue to ſow the Seeds of Creſſes, Rape, Turnep, Radiſh, Muſtard, and other kinds of Sallet-herbs every Week, that the Table may not be unfurniſhed; for theſe ſoon grow too large for Uſe.

Gather all Sorts of Kitchen-Garden Seeds which are now ripe, ſpreading them upon Mats to dry, and then beat or rub them out of their Huſks or Pods, and put them up till the Seaſons for ſowing them.

Your Radiſh-ſeed, which is now in Pod, muſt be guarded, to prevent the Birds from devouring it, which they will do in a ſhort time, if they are not deſtroyed.

Sow Turneps for a latter Crop, which may be done any time before the Twentieth Day of this Month; but thoſe which are ſown later, do ſeldom apple well, eſpecially if the Autumn proves cold.

Earth up your Finnochia, which is full grown, to blanch it, that it may be fit for Uſe; and continue to tranſplant Celery into Drills, that you may have a Succeſſion to ſupply the Table thro' the Seaſon.

Products of the Kitchen-Garden *this Month.*

Cabbages, Kidney-beans, ſome large kinds of Peaſe, Artichokes, Garden-Beans, Carrots, Cabbage-Lettuces of ſeveral Sorts, Finnochia, Celery, Turneps, Cucumbers, Melons, Onions, Purſlain, all Sorts of young Sallet-herbs, ſome late Cauliflowers, Endive, and ſome other Sorts.

Work to be done in the Fruit Garden *and* Vineyard.

Look carefully over your Wall-fruit-trees to deſtroy Snails and other Vermin, which will gnaw your choice Fruits, and ſpoil them. You ſhould alſo deſtroy Sparrows and Tomtits, which will peck your choice Pears, Figs, and Grapes, as faſt as they ripen, where they are not defended; and you ſhould fix ſome Phials with Honey-water on different Parts of your Trees, to deſtroy the Waſps, which will drown themſelves by attempting to drink of the Water.

Where any Branches of your Trees do project from the Wall, or have been diſplaced by Winds, *&c.* they ſhould be carefully faſten'd to the Wall in their due Poſition, that the Fruit may receive the Benefit of the Sun to ripen it; but do not pull off the Leaves of the Trees, (as is by ſome Perſons practiſed) for this expoſes the Fruit too much, whereby it becomes hard, and ſeldom ripens kindly.

Your Vines in the Vineyard, and thoſe againſt the Walls, ſhould now be gone over for the laſt Time, pulling off all trailing Branches which have been lately produced; and faſten thoſe Branches which are looſe in their proper Places, that the Fruit (which is now full grown) may receive the Benefit of the Sun and Air to ripen it. You ſhould alſo obſerve to keep the Ground clear from Weeds between your Rows of Vines, that the Sun may dry up the Moiſture of the Ground every Day, and the Reflexion of Heat may be greater.

Untie the Buds of Fruit-trees which were inoculated the laſt Month, otherwiſe their Bandage will pinch the Bark of the Stocks, and prevent their growing equally in the Part where the Bud is put in. You ſhould alſo obſerve to clear the lower Part of your Stocks from Shoots, and keep the Ground clear from Weeds near the Roots of your Fruit-trees.

Fruits in prime, or yet laſting.

Apples; The Summer white Couſtin, Margaret Apple, Codlin, Summer Pearmain, Summer Pippin, with ſome others.

Pears; The Jargonelle, Windſor, Cuiſſe Madam, Orange Muſk, Gros Blanquette, Muſk Blanquette, Long-ſtalk'd Blanquette, Poire ſans Peau, Muſcat Robine, Amber Pear, Green Orange, Caſſolette, Magdalen Pear, Gros Oignonet, Poire Roſe, Summer Boncretien, Cailot Roſat, Ruſſellet, with ſome others of leſs Note.

Peaches; Red and white Magdalen, Early Newington, the Mignonne or Minion, Italian Peach, Nobleſs, Bellows or Bellis, Violette Hative, La Chevreuſe, (or Belle Chevreuſe) Early Admirable, Albemarle, Violet Peach, Nivette Peach, Montaubon, Royal George, Teton de Venus, purple Alberge, Chancellor, with ſome others.

Nectarines; Roman Red, Elruge, Newington, Brugnon, Italian, Murray, and Temple's.

Plums; Orleans, white Perdrigon, Violet Perdrigon, red Imperial, white Imperial or Bonum Magnum, Le Royal, Cheſton Plum, Drap d'Or, St. Katharine, Roche Courbon, Reine Claude, Myrabolan, green Gage, La Mirabelle, Abricot Plum, Prune Monſieur, Maitre Claude, Royale Dauphin, with ſome others.

Grapes; The July, white Sweet-water, black Cluſter, Munier, Chaſſelas, white Muſcadine, and Orleans.

Figs; The Early White, Long Blue, Long White, Round Blue, Italian White, Large Yellow, Brunſwick, and Cyprus Fig.

Filberts; Nuts, Mulberries; and in the Stove, the Anana or Pine-Apple.

Work to be done in the Nursery.

The Beginning of this Month you ſhould look carefully over the Stocks which were budded the laſt Month, and looſen the Bandage, leſt the Buds ſhould be pinch'd thereby; and where there are any Shoots produced below the Buds, they ſhould be cut off. You ſhould alſo look over your Trees which were budded the former Year, or grafted in the Spring, cutting off all ſuch Shoots as are produced below the Buds or Grafts; for if theſe are permitted to grow, they will ſtarve the Buds or Grafts.

Keep your Ground clear from Weeds between your Trees, and train up the ſeveral Sorts of Ever-greens, Foreſt Trees, and Shrubs, for the ſeveral Purpoſes they are deſigned; but do not trim the Stems of Standard Trees too cloſe; for if they have not ſome ſmall Shoots left on the Sides of their Stems to detain the Sap, they will not be able to ſupport their Heads.

Toward the End of this Month you may plant Cuttings of Laurels, and Honeyſuckles, in a ſhady Border, obſerving to keep them conſtantly refreſhed with Water; for if they ſhrink with Drought, they ſeldom recover again.

You ſhould now begin to clear and trench the Ground, where you intend to plant out Stocks, or young Foreſt Trees in Autumn, that the Rain may ſoak and mellow the Ground before the Seaſon of planting; and if your Land is ſtiff, the laying of it a Month or ſix Weeks in Ridges before it is planted, will mellow the Clods, and render them much eaſier to be broken, than if it was newly dug.

Work to be done in the Pleasure Garden.

Tranſplant the Layers of Carnations, Pinks, and Sweet-Williams, which by this Time will have taken good Root, if timely laid. Thoſe choice Sorts of Carnations which are deſigned for Pots, may be planted at this Time each in a ſmall Half-penny Pot, filled with freſh light Earth, and placed in a ſhady Situation until they have taken Root; after which they may be removed into a more open Situation, where they may remain until the Beginning of *October*, when they ſhould be placed under a Hot-bed Frame, or plunged into an old Bark-bed, and arched over with Hoops, that they may be cover'd in Winter, to protect them from hard Rains, Snow, and ſevere Froſt; but they ſhould be always open'd in mild Weather, otherwiſe they will draw up weak. In this manner they may be much better preſerved, than if they were planted out at firſt into the Pots where they are to remain for blowing, becauſe they will ſtand in a ſixth part of the Compaſs; and in Spring they may be turn'd out of the ſmall Pots with the Earth to their Roots, whereby they will not receive any Check, and placed into larger Pots to flower. But thoſe Carnations, Pinks, and Sweet-Williams, which are deſigned for the Borders of the Pleaſure Garden, ſhould be now planted in Beds in the Flower Nurſery, to remain till the Middle or latter End of next Month, when you muſt dig the Borders of the Pleaſure Garden, and new plant them, at which time theſe may be taken up with a Ball of Earth to their Roots, and planted in the Borders with other Flowers.

You may now ſhift your choice Auricula's into freſh rich Earth, obſerving to clear them from dead Leaves, and place them in a ſhady Situation until they have taken Root: This freſh Earth will ſtrengthen the Plants greatly, and improve their Flowers the following Spring.

You may remove the Bulbs of Iris's, Fritillaria's, and Hyacinths of *Peru*, and alſo the Roots of Lilies, Martagons, Crown Imperials, Pæonia's, and Flag-Iris's, whoſe Leaves are now decayed; but if ſuffered to remain longer in the Ground, will puſh out freſh Fibres, when it will be too late to remove them.

Gather all ſorts of Flower-ſeeds as they ripen, and ſpread them to dry in the Sun; after which they ſhould be preſerved in their Pods or Husks until the Seaſons for ſowing them; for the Seeds of moſt Plants may be kept longer good in their Pods than when they are rubb'd out.

Tranſplant Polyanthus's, Primroſes, and ſeedling Auricula's, obſerving to ſhade and water them until they have taken Root, as alſo to cloſe the Earth to their Roots, otherwiſe the Worms will draw them out of the Ground.

Cut down the Stalks of ſuch Plants as have done flowering, and are decayed; and faſten all tall growing Plants to Sticks, to ſupport them from being broken or blown down by ſtrong Winds, which often reign at this Seaſon.

Your Pots of annual Plants muſt now be duly water'd in dry Weather, otherwiſe they will ſoon loſe their Beauty; and ſuch of them as are tender, ſhould be removed into Shelter when the Nights begin to be cold, that they may perfect their Seeds, which in bad Seaſons do ſeldom ripen well, if they are not protected from the Inclemency of the Weather.

Toward the latter End of this Month you ſhould begin to prepare your Beds to receive your choice Hyacinths, Tulips, and Ranunculus's, that the Earth may ſettle before the Roots are planted; otherwiſe, when the Earth ſinks unequally, there will be Holes on the Tops of the Beds, which will detain the Water, whereby the Roots in thoſe Places will be rotted.

Clean all the Parts of your Flower-Garden from Weeds, which, if permitted to ſtand, will ſhed their Seeds in a ſhort time, whereby your Garden will be ſo ſtock'd with Weeds, as not to be rooted out in ſeveral Years.

You may now ſow the Seeds of Anemonies, Pulſatilla's, Ranunculus's, Crocus's, Fritillaria's, Hyacinths, Tulips, Narciſſus's, Cyclamens, Iris's, *&c.* in Pots or Boxes, filled with light rich Earth, obſerving not to cover thoſe Seeds which are thin and light, too deep; for theſe will rot in the Ground when buried deep, as the Ranunculus's, Pulſatilla's, Anemonies, and Fritillaria's; but the larger Seeds may be covered thicker. Theſe Pots or Boxes ſhould be placed where they may have the Morning Sun till Ten or Eleven o'Clock; for if they are too much expoſed to the Heat of the Sun at this Seaſon, the Seeds will not grow ſo well: They muſt alſo be frequently refreſh'd with Water, but it ſhould be given very gently, otherwiſe the Seeds will be in danger of being waſhed out of the Ground.

The Seeds of ſeveral Kinds of annual Flowers may now be ſown on warm Borders to ſtand the Winter, that they may flower early the following Summer, whereby they will be much ſtronger, and produce a greater Quantity of Flowers, than thoſe which are ſown in the Spring, and the Seeds will conſtantly ripen better. Of theſe are the Sweet Pea, Venus Navelwort, Dwarf Annual-Stock, Lobel's Catchfly, with ſome others.

Plants now in Flower in the PLEASURE-GARDEN.

Some Carnations, Painted Lady Pink, Old Man's-head Pink, Female Balſamine, Marvel of Peru, Amaranthus's, Amaranthoides, ſeveral ſorts of Starwort, Golden-Rods of ſeveral Kinds, Scarlet and Blue Cardinals-Flower, Campanula, Hollyhocks, Colchicum of Chio, Cyclamens, Greater Convolvulus of ſeveral Sorts, Flos Adonis, Venus Looking-glaſs, Venus Navelwort, Africans, French Marygold, Sweet Sultans, Indian Scabious, Nigella's, Candy Tuft, Apocynums, Sweet Pea, Tangier Pea, Everlaſting Peaſe, Sun-Flowers of many Kinds, Lavatera's, Mallows of ſeveral ſorts, Linaria's, Jacea's, Ketmia Veſicaria, Hieraciums, Stramoniums, Tuberoſes, Sclarea's, Geraniums, Lychnis's, Annual Stocks, Blattaria Lutea, Double Ptarmica, Xeranthemums, two Sorts of Marygolds from the *Cape of Good Hope*, Onagra's, Lyſimachia's, Veronica's, Autumnal Hyacinth, Globe Thiſtles, Dwarf Annual Stock, Naſturtium Indicum, Fairchild's Mule, Virginian Spiderwort, Catanance Quorundam, Elichryſum Americanum. Stœchas Citrina, Double Feverfew, Coronilla Herbacea flore vario, Buphthalmums, Aſteroides Alpina ſalicis folio, Eryngiums, Glauciums, Capnoides, Aſclepias albo flore, Aconitum Lycoctonum luteum, Aconitum ſalutiferum, Napellus cœruleus, Alcea's, Helianthemums, Double Sopewort, Argemone Mexicana, Antirrhinums, Lupines of ſeveral ſorts, Lavendula folio diſſecto, Iris Uvaria, Cerinthe, Perſicaria Orientalis, Alkekengi's, Limoniums, Moldavica's, Molucca lævis & ſpinoſa, Solanums of various Kinds, Melongena's, Hedyſarums, Phalangiums, Oriental Bugloſs, Alyſſons, with ſome others.

Hardy Trees and Shrubs now in Flower.

Common white Jaſmine, Paſſion-Flower, Periploca, Scorpion Senna, Althæa fruteſcens Bryoniæ folio, Agnus Caſtus, Althæa fruteſcens parvo flore, Kitmia's four ſorts, Honeyſuckles, Mallow-tree, Shrubby Canary Hypericum, Stinking ſhrubby Hypericum, Lauruſtinus, Double Virgin's-Bower, Bignonia, or Trumpet Flower, Traveller's Joy, Muſk Roſe, Monthly Roſe, Bladder Senna, Spaniſh Broom, with ſome others.

Work to be done in the GREEN-HOUSE, GARDEN *and* STOVE.

About the Beginning of this Month you may inoculate Orange-trees, obſerving to turn that Side of the Stock where the Bud is put in, from the Sun. Cut off Oranges, Jaſmines, and other Exoticks which were enarch'd the former Spring, from their Mother-trees, being careful in the Operation not to looſen the Graft from the Stock, nor ſhould the Clay or Wax be rubb'd off until the following Spring.

The Beginning of this Month is a proper Seaſon for ſhifting Aloes, Sedums, Ficoides's, Cereus's, Euphorbiums, and other exotick ſucculent Plants which now begin to grow, and will take Root again ſooner than at any other Time of the Year; you ſhould at the ſame time take off the Off-ſets of your Aloes, and plant them into ſmall Pots filled with freſh ſandy Earth, placing them where they may have the Morning Sun, obſerving to refreſh them now and then with a little Water in dry Weather, which if duly obſerved, there will be no Occaſion to give them any artificial Heat to encourage them to take Root, for at this Seaſon they are greatly diſpoſed to ſend forth Roots.

The ſeveral Kinds of tender Exotick Plants, which are conſtantly preſerved in the Bark-ſtoves, ſhould now be ſhifted, that they may make ſtrong Roots before Winter; for if they are ſhifted too late in the Seaſon, they do not recover it before the Cold comes on, which checks their Growth, ſo that they will not appear ſo vigorous, nor will they be ſo ſtrong to maintain themſelves in Winter; but if they are not ſhifted at this Seaſon, their Roots will be ſo matted in the Pots, that they will grow mouldy in Winter, and decay, which has often been deſtructive to many choice Plants.

Your Beds in which your Anana's are placed, ſhould be now refreſhed with ſome freſh Tanners-Bark, (provided it was not done the former Month) for the Evenings at this Seaſon do begin to grow cold, and if the Heat of the Beds do alſo decline, the Plants will not thrive; and this being the principal Seaſon of their Growth, it will prevent their ſtrengthening themſelves for Fruit the following Year; nor will the Heads or Off-ſets which have been newly planted, be ſufficiently furniſhed with Roots before Winter, if the Beds are not kept in a kindly Temper of Warmth; and as the Nights grow cold, the Glaſſes ſhould be cover'd with Mats, to keep them warm.

The ſeveral Kinds of hardy Green-houſe Plants ſhould now be ſhifted, and thoſe which require it, ſhould have larger Pots; for if their Roots are too much confined, and matted about the Pots, they will grow mouldy, and decay. When they are ſhifted, they ſhould be placed in a ſhady Situation, until they have taken Root, after which they may be expoſed again in the Sun, until the Time of houſing them: But you ſhould not expoſe them too much to ſtrong Winds, which will blow them out of the Pots again, when they have been lately removed.

You ſhould now take ſome of the Earth out of the Tubs or Pots of Orange-trees, filling them up again with rich freſh Earth, which will encourage them to ſupport their Fruit in Winter.

Waſh and cleanſe the Leaves and Stems of your Coffee-trees, and other Exotick Plants, from Filth, which they are very ſubject to contract at this Seaſon; and if it be not clean'd off, will intice Vermin, to the great Injury of your Plants.

Toward the latter End of the Month, you may remove your Cereus's, Euphorbiums, and other ſucculent Plants, which have been placed abroad, into the Stove again; for at this Seaſon the Nights begin to grow cold, and there often happens much Rain, which is very injurious to theſe Plants, when they are expoſed thereto.

Plants now in Flower in the GREEN-HOUSE, GARDEN, *and* STOVE.

Geraniums of ſeveral ſorts, Ficoides's of various kinds, Fritillaria Craſſa, ſeveral ſorts of Aloes, Sedums, Cotyledons, Myrtles, Oranges, Ciſtus's, Colutea Æthiopica, ſeveral ſorts of Paſſion-Flower, Senſitive Plant, Humble Plant, Indian Figs, Oleanders, Alcea's, Anemonoſpermos's, Myrto-Ciſtus, Ricinoides Staphyſagriæ folio, Ricinoides folio multifido, Quamoclit, Spaniſh Jaſmine, Arabian Jaſmine, Azorian Jaſmine, Indian yellow Jaſmine, Laurel-leaved Jaſmine, and Ilex-leaved Jaſmine, Apocynums, Acacia's, Senna Alexandrina, Caſſia's of ſeveral ſorts, Hedyſarums, Viburnums, Elichryſums, Indian Naſturtium with a double Flower, Jacobea's, Doria's, Senecio folio retuſo, Canna Indica, Fabago's, Trachelium umbellatum Azureum, Limonium Aſplenii folio, Limonium Siculum Gallas ferens, Turnera, Colvolvulus's of ſeveral ſorts, Plumeria, Phytolacca, Solanoides, Poliums, Solanums, Lotus argentea Cretica, Martynia, Indian Arrow-root, Aloes of ſeveral ſorts, with ſome others.

AURANTIUM, [this Plant is called of *Aurum, Lat.* Gold, on account of its Golden Colour; or, as others ſuppoſe, of the Province of *Orange*] The Orange-tree.

The *Characters* are;

The Leaves have two Lobes or Appendages at their Baſe, which are like Ears, and cut in Form of a Heart; the Fruit is round and depreſſed, and of a yellow Colour when ripe; the Juice is ſweet, in which it differs from the Citron *and* Lemon.

There is a very great Variety of this Tree preſerved in the Gardens of the Curious; to enumerate them all, would be too tedious in this Place; I ſhall therefore only mention the beſt known Sorts, and proceed to their Culture.

1. AURANTIUM *acri medulla, vulgare. Ferr. Heſp.* The common *Sevil* Orange.
2. AURANTIUM *medulla dulci, vulgare. Ferr. Heſp.* The ſweet *Sevil* Orange.
3. AURANTIUM *Sinenſe. Ferr. Heſp.* The *China* Orange.
4. AURANTIUM *criſpo folio. Ferr. Heſp.* The curl'd-leav'd Orange.
5. AURANTIUM *criſpo folio, elegantiſſime variegato. Boerh. Ind.* The ſtriped curl'd-leav'd Orange.
6. AURANTIUM *corniculatum. Ferr. Heſp.* The horned Orange.
7. AURANTIUM *folio variegato, vulgare, Anglicum dictum, Boerh. Ind.* The common ſtriped Orange.
8. AURANTIUM *hermaphroditum, partim Aurantium, partim Citrium.* The Hermaphrodite Orange.
9. AURANTIUM *anguſto ſalicis folio dictum. Boerh. Ind.* The Willow-leav'd Orange, *commonly call'd*, The *Turkey* Orange.
10. AURANTIUM *anguſto ſalicis folio, elegantiſſime variegato.* The ſtriped *Turkey* Orange.
11. AURANTIUM *fructu maximo, Indiæ Orientalis. Boerh. Ind.* The Pumpelmoes, *or* Shaddock.
12. AURANTIUM *flore duplici.* The double flower'd Orange.
13. AURANTIUM *fructu minimo.* The Nutmeg *or* Dwarf Orange.
14. AURANTIUM *fructu minimo, foliis ex albo variegatis.* The ſtriped Nutmeg *or* Dwarf Orange.

There is alſo a great Variety of *Oranges* with ſtriped Leaves, to be found in the curious Collections of theſe Trees, which differ in the Colour or Manner of the Stripes or Blotches; but theſe I ſhall paſs over, and proceed firſt to the Manner of raiſing them from Seed.

If you purpoſe to raiſe Stocks for budding of *Oranges*, you ſhould procure ſome *Citron*-Seeds which were duly ripen'd; for the Stocks of this Kind are preferable to any other, both for Quickneſs of Growth, as alſo that they will take Buds of either *Orange*, *Lemon*, or *Citron*: The beſt Seeds are uſually to be had from rotten Fruits, which are commonly eaſy to be procured in the Spring of the Year: Then prepare a good Hot-bed of either Horſe-dung or Tanners-bark, the laſt of which is by much the better, if you can eaſily procure it: When this Bed is in a moderate Temper for Heat, you muſt ſow your Seeds in Pots of good rich Earth, and plunge them into the Hot-bed, obſerving to give them Water frequently, and ſhade the Glaſſes with Mats in the great Heat of the Day; and raiſing the Glaſſes to give proper Air, leſt the Seeds ſhould ſuffer by too great Heat: In three Weeks Time your Seeds will come up; and if the young Plants are not ſtunted, either for want of proper Heat or Moiſture, they will be, in a Month's Time after their Appearance, fit to tranſplant into ſingle Pots; you muſt therefore renew your Hot-bed; and having prepared a Quantity of ſmall Half-penny Pots, (which are about five Inches over at the Top) fill theſe half full of good freſh Earth, mix'd with very rotten Cow-dung; and then ſhake out the young Plants from the large Pots, with all the Earth about them, that you may the better ſeparate the Plants without tearing their Roots; and having put a ſingle Plant into each of the ſmall Pots, fill them up with the ſame Earth as before directed, plunging the Pots into the new Hot-bed, giving them a good Watering to fix the Earth to their Roots, and obſerve to repeat the ſame very often, (for this Plant, when in a Hot-bed, requires much Water) and be ſure to ſcreen them from the Sun in the Heat of the Day: In this Method, with due Care, your Plants will grow to be two Feet high by *July*, when you muſt begin to harden them by degrees, in raiſing your Glaſſes very high; and when the Weather is good, take them quite off, but do not expoſe them to the open Sun in the Heat of the Day, which would be very injurious to them, eſpecially while young: Toward the End of *September* you muſt houſe them, obſerving to place them near the Windows of the Green-houſe, to prevent the Damps from moulding their tender Shoots: During the Winter-ſeaſon they may be often refreſhed with Water, but it muſt be done ſparingly, giving them but a little each Time; and in *March* or *April*, waſh their Heads and Stems, to clear them from the Filth that may have ſettled thereon, during their being in the Houſe; and you muſt alſo give them a gentle Hot-bed in the Spring, which will greatly forward them; but harden them by the Beginning of *June*, that they may be in right Order to bud in *Auguſt*, when you ſhould make Choice of Cuttings from Trees that are healthy and fruitful, of whatever Kinds you pleaſe, obſerving that the Shoots are round, the Buds of theſe being much better and eaſier to part from the Wood than ſuch as are flat: When you have budded the Stocks, you ſhould remove them into a Green-houſe, to defend them from Wet, turning the Buds from the Sun; but let them have as much free Air as poſſible, and refreſh them often with Water: In a Month's Time after budding, you will ſee which of them has taken; you muſt then untie them, that the Binding may not pinch their Buds, and let them remain in the Green-houſe all the Winter, and in the Spring prepare a moderate Hot-bed of Tanners-bark; and after having cut off the Stocks about three Inches above the Buds, plunge their Pots into the Hot-bed, obſerving to give them Air and Water, as the Heat of the Weather ſhall require; but be ſure to ſcreen them from the violent Heat of the Sun during the Heat of the Day: In this Management, if your Buds ſhoot kindly, they will grow to the Height of three Feet by *July*; at which time you muſt begin to harden them before the cold Weather comes on, that they may the better ſtand in the Green-houſe the following Winter: and as this will be a ſufficient Height for the Stems, you may ſtop the leading Shoot, in order to force out lateral Branches: In the firſt Winter after their ſhooting, you muſt keep them very warm; for by forcing them in the Bark-bed, they will be ſomewhat tenderer; but it is very neceſſary to raiſe them to their Height in one Seaſon, that their Stems may be ſtrait: for in ſuch Trees which are two or more Years growing to their heading Height, the Stems are always crooked: In the ſucceeding Years, their Management will be the ſame as in full-grown Trees, which will be hereafter treated of; I ſhall therefore now proceed to treat of the Management of ſuch Trees as are brought over every Year in Cheſts from *Italy*; which is, indeed, by much the quicker Way of furniſhing a Green-houſe with large Trees; for thoſe which are raiſed from Seeds in *England*, will not grow ſo large in their Stems under ten or twelve Years as theſe will have when brought over; and altho' their Heads are ſmall when we receive them, yet in three Years, with good Management, they will obtain large Heads, and produce Fruit.

In the Choice of theſe Trees, obſerve, firſt, the Difference of their Shoots and Leaves, (if they have any upon them) to diſtinguiſh their different Sorts; alſo prefer thoſe that have two good Buds in each Stock, (for many of them have but one, which will always produce an irregular Head;) the Straitneſs of the Stem, Freſhneſs of the Branches, and Plumpneſs of the Bark, are neceſſary Obſervations.

When you have furniſhed yourſelf with a Parcel of Trees, you muſt prepare a moderate Hot-bed of Tanners-bark, in Length and Breadth according to the Number of Trees; then put your Trees into a Tub of Water upright, about half-way of the Stems, leaving the Head and upper Part of the Stem out of the Water, the better to draw and imbibe the Moiſture: In this Situation they may remain two or three Days, (according to their Plumpneſs when you received them) then take them out, and clean their Roots from all Filth, cutting off all broken or bruiſed Roots, and all the ſmall Fibres, which are quite dried by being ſo long out of the Earth, and ſcrub the Stems with an hard Hair-bruſh, cleaning them afterwards with a Cloth; then cut off the Branches about ſix Inches from the Stem; and having prepared a Quantity of good freſh Earth, mix'd with very rotten Neats-dung, plant your Trees therein, obſerving never to put them into large Pots; for if they are but big enough to contain their Roots, it is ſufficient at firſt planting; and be ſure to put ſome Potſheards and large Stones in the Bottom of each Pot, to keep the Holes at the Bottom of the Pots from being ſtopp'd with Earth, that the Water may freely paſs off; then plunge theſe Pots into the Bark-bed, watering them well to ſettle the Earth to their Roots, frequently repeating the ſame as they may require it; and obſerve to ſcreen the Glaſſes of your Hot-bed from the Sun in the Heat of the Day.

If your Trees take to grow kindly, (as there is little Reaſon to doubt of it, if the Directions given be duly obſerved) they will have made ſtrong Shoots by the Beginning of *June*; at which Time you ſhould ſtop their Leaders, to obtain lateral Branches to furniſh their Heads: and now you muſt give them Air plentifully, and begin to harden them, that in the Middle of *July* they may be removed into the open Air, in ſome warm Situation, defended from the great Heat of the Sun and Winds, that they may be harden'd before Winter: About the End of *September* you ſhould houſe theſe Plants, ſetting them at firſt in the Front of the Green-houſe near the Glaſſes, keeping the Windows open at all Times when the Weather will permit; and about the latter End of *October*, when you bring in the

Myrtles, and other leſs tender Trees, you muſt ſet your *Oranges* in the warmeſt and beſt Part of the Houſe, placing lower Plants or Trees in the Front to hide their Stems: During the Winter, let your Waterings be frequent, but give them but little at a Time; for now their Heads are but ſmall, and therefore incapable to diſcharge too great a Quantity of Moiſture; and take great Care to guard them from Froſt.

In the Spring, when you begin to take out ſome of your hardieſt Sorts of Plants, to thin your Houſe, waſh and cleanſe the Stems and Leaves of your *Orange-Trees*, taking out the upper Part of the Earth in the Pots, filling them up again with good, freſh, rich Earth, laying thereon a little rotten Neats-dung round the Outer-ſide of the Pots, but do not let it lie near the Stem of the Trees; then place them at wider Diſtances in the Houſe, that the Air may circulate round their Heads, giving them Air diſcretionally as the Weather grows warm; but do not remove them into the open Air until the Middle of *May*, that the Weather is ſettled; for many Times, when they are removed out too ſoon, the Mornings often proving Cold, give them at leaſt a great Check, and many Times kill the extreme weak Part of the Shoots: Let the Situation for your *Orange*-Trees, during the Summer Seaſon, be as much defended from the Sun in the Heat of the Day, and ſtrong Winds, as poſſible, by tall Trees and Hedges, both of which, if they are expoſed thereto, are very hurtful to them.

As theſe Trees advance, it will be neceſſary in the Summer to ſtop ſtrong Shoots, when they grow irregular, to force out lateral Branches to fill the Head; but do not pinch off the Tops of all the Shoots, (as is the Practice of ſome) which will fill the Tree with ſmall Shoots, too weak to ſupport Fruit; but endeavour to form a regular Head, and obtain ſtrong Shoots, taking away weak trifling Branches where they are too cloſe.

During the Summer Seaſon your *Orange*-Trees will require frequent and plentiful Waterings in dry Weather, eſpecially if they are large; therefore you ſhould endeavour to have the Water as near the Trees as poſſible, to ſave the Trouble of carrying it, which, in a large Quantity of Trees, takes up much Time: Your Water ſhould be ſoft, and expoſed to the Air, but never add Dung of any ſort thereto, which, altho' by many frequently recommended, yet has always been found deſtructive to theſe and all other Trees, if much uſed; it being like hot Liquors to human Bodies, which at firſt taking ſeem to add Vigour, yet certainly leave the Body weaker after ſome Time than before.

Your *Orange*-Trees will require to be ſhifted and new potted every Year; therefore you muſt prepare a Quantity of good Earth, at leaſt a Year before you intend to uſe it, that it may be well mix'd, and perfectly rotten: the beſt Seaſon for this Work is about the End of *April*, that they may have taken freſh Root before they are removed out of the Green-houſe; and when this Work is performed, it will be neceſſary to let them remain in the Houſe a Fortnight longer than uſual, to be well ſettled.

In the performing this Work, after you have drawn the Trees out of the Pots, you muſt cut off all the Roots round the Outſide of the Ball of Earth, and take away all mouldy Roots, (if any ſuch be) then with a ſharp Iron Inſtrument, get as much of the old Earth from between the Roots as poſſible, being careful not to break or tear the Roots; then ſet the Root of the Tree into a large Tub of Water, for about a Quarter of an Hour, to ſoak the under Part of the Ball of Earth; and afterwards ſcrub the Stems of the Trees with a hard Hair-bruſh, cleaning them and the Heads with Water and a ſoft Woollen Cloth; your Pots being prepared, with ſome Potſheards and large Stones in the Bottom, put ſome of your freſh Earth into the Pot, about two Inches thick, and having placed your Tree thereon in the Middle of the Pot upright, fill it up with the ſame rich Earth, preſſing it down hard with your Hands; then water the Tree all over the Head, with a Watering-pot that has a Roſe upon the Spout, to let the Water fall light and thick, (as in a Shower of Rain;) and in watering theſe Trees, do it in the ſame Manner, during the Time they abide in the Houſe after ſhifting; this will greatly refreſh their Heads, and promote their taking freſh Roots.

When you firſt ſet theſe Trees abroad after ſhifting, you ſhould place them near the Shelter of Hedges, and faſten their Stems to ſtrong Stakes, to prevent their being diſturbed by Winds, which ſometimes will blow freſh-planted Trees out of the Pots, if too much expoſed thereto, and thereby greatly injure their new Roots.

If old *Orange*-Trees have been ill managed, and their Heads become ragged and decayed; the beſt Method to reſtore them, is, to cut off the greateſt Part of their Heads early in *March*, and draw them out of the Tubs or Pots, and ſhake off the Earth from their Roots, cutting away all ſmall Fibres and mouldy Roots; and then ſoak and clean their Roots, Stems, and Branches, planting them into good Earth, and ſetting them into a Hot-bed of Tanners-bark, as was directed for ſuch Trees as came from Abroad, managing them in the ſame Manner; by this Method they will produce new Heads, and in two Years time become good Trees again. But if theſe are large Trees, and have grown in Tubs for ſeveral Years, your beſt Way will be, to prepare a Parcel of rough Baſkets, (ſuch as are uſed for baſketing Ever-greens, when ſent to a diſtant Place;) let theſe be ſomewhat leſs than the Tubs you deſign to plant your Trees into, then plant your Trees herein, plunging them into the Hot-bed; and about the Beginning of *July*, when your Trees have good Shoots, you may remove them into the Tubs, with their Baſkets about them, filling the empty Space with the ſame good Earth; this will preſerve your Tubs from rotting in the Bark, and the Trees will do equally as well as if planted into the Tubs at firſt, provided you are careful in removing the Baſkets not to diſturb their Roots; and alſo, let them remain in the Green-houſe a Fortnight or three Weeks after planting, before you ſet them abroad.

Theſe Trees being new potted or tubb'd every other Year, thoſe Years in which they are not ſhifted, you muſt in *April* obſerve to take out as much of the old Earth from the Tops of the Pots and Tubs, and alſo round the Sides of them, as poſſible, without injuring the Roots of the Trees, and fill them up with freſh Earth; you muſt alſo waſh and clean their Stems and Leaves from Filth, which will greatly ſtrengthen their flowering, and cauſe them to ſhoot vigorouſly the following Summer.

In the Management of *Orange*-Trees which are in good Health, the chief Care ſhould be to ſupply them with Water duly, and not (as is ſometimes practiſed) ſtarve them in Winter, whereby their Fibres are dried, and become mouldy, to the great Prejudice of the Trees; nor to give them Water in too great abundance; but rather let their Waterings be frequent, and given in moderate Quantities. You muſt alſo obſerve that the Water has free Paſſage to drain off; for if it be detained in the Tubs or Pots, it will rot the tender Fibres of the Trees. During the Winter Seaſon they muſt have a large Share of Air, when the Weather is favourable; for nothing is more injurious to theſe Trees than ſtifling of them; nor ſhould they be placed too near each other in the Green-houſe; but ſet them at ſuch Diſtance, that their Branches may be clear of each other, and that the Air may circulate freely round their Heads. In Summer they ſhould be placed where the Winds are not violent, and to have the Morning and Evening Sun; for if they are too much expoſed to the Mid-day Sun, they will not thrive. The beſt Situation for them is near ſome large Plantation of Trees, which will break the Force of the Winds, and ſcreen them from the violent Heat of the Sun. In ſuch a Situation they may remain until the Beginning of *October*, or later, according as the Seaſon proves favourable; for if they are carried into the Green-houſe early, and the Autumn ſhould prove warm, it will occaſion the Trees to make freſh Shoots, which will be weak and tender, and ſo liable to periſh in Winter, and ſometimes it will occaſion the Flowering in Winter, which greatly weakens the Trees.

The *Shaddock* and *Citron* are much tenderer than either the *Orange* or *Lemon*, ſo ſhould be ſet into the Green-houſe ſooner, and have a warmer Situation in Winter, otherwiſe their Fruit will all drop off.

The beſt Compoſt for *Orange*-Trees is Two-thirds of freſh Earth from a good Paſture, which ſhould not be too light, nor over-ſtiff, but rather a Hazel Loam; this ſhould be taken about ten Inches deep with the Sward, which ſhould be mixed with the Earth to rot, and One-third Part of Neats-dung; theſe ſhould be mixed together, at leaſt twelve Months before it is uſed, obſerving to turn it over every Month, to mix it well, and to rot the Sward; this will alſo break the Clods, and cauſe the Mould to be finer. Before you make uſe of this Earth, you ſhould paſs it thro' a rough Screen, to ſeparate the great Stones and the Roots of the Sward therefrom; but by no means ſift the Earth too fine, for this is very prejudicial to moſt Plants, but particularly to *Orange*-Trees.

AURICULA MURIS, or PILOSELLA; Mouſe-ear.

This is a ſort of Hawkweed, with ſmall hairy Leaves, which are white underneath; the Plant trails upon the Ground, taking Root at the Joints, by which Means it will ſoon ſpread over a large Compaſs of Ground.

This is very common in *England*; it grows chiefly on dry barren Places, or upon old Walls.

AURICULA URSI, [*i. e.* Bear's-ear; ſo called, becauſe the Antients fancied it reſembled the Ear of a Bear] Bear's-ear, or Auricula.

The *Characters* are;

It hath a perennial Root; the Leaves are ſmoother and thicker than thoſe of the Primroſe; the Cup of the Flower is ſhorter, ſo that the Tube appears naked; the Flower is ſhaped like a Funnel, the upper Part is expanded and divided into five Segments; this is ſucceeded by a globular Seed-veſſel, containing many ſmall Seeds.

To enumerate the Diverſities of this Plant, would be almoſt endleſs and impoſſible: for every Year produces vaſt Quantities of new Flowers, differing in Shape, Size, or Colour of the Flowers; and alſo in the Leaves of theſe Plants, there is as great a Variety, ſo that the ſkilful Floriſt is oftentimes capable of diſtinguiſhing the particular Sorts thereby.

But as it ſeldom happens, that ſuch of theſe Flowers as are at one Time in great Eſteem, continue to be regarded a few Years after, (there being ſtill finer or larger Flowers produced from Seeds, which are what the Floriſts chiefly ſeek after) ſo it would be needleſs to mention any of them: Wherefore I ſhall proceed to give the Characters of a good *Auricula.*

1. *The Stem of the Flower ſhould be lofty and ſtrong.*
2. *The Footſtalk of the Flower ſhould be ſhort, that the Umbel may be regular and cloſe.*
3. *The Pipe or Neck of each Flower ſhould be ſhort, and the Flowers large and regularly ſpread, being no ways inclinable to cup.*
4. *That the Colours are very bright, and well mixed.*
5. *That the Eye of the Flower be large, round, and of a good White, or Yellow, and that the Tube or Neck be not too wide.*

All the Flowers of this Kind, that want any of the above-mentioned Properties, are now rejected by every good Floriſt; for as the Varieties every Year increaſe from Seeds, ſo the bad ones are turn'd out to make Room for their Betters; but in ſome People the Paſſion for new Flowers ſo much prevails, that ſuppoſing the old Flower greatly preferable to a new one, if it is of their own raiſing, the latter muſt take Place of the old one.

In order to obtain good Flowers from Seeds, you muſt make choice of the beſt Flowers you have, which ſhould be expoſed to the open Air, that they may have the Benefit of Showers, without which they ſeldom produce good Seeds; the Time of their Ripening is in *June*, which you will eaſily know, by their Seed-veſſel turning to a brown Colour, and Opening; you muſt therefore be careful leſt the Seeds be ſcatter'd out of the Veſſel, for it will not be all fit to gather at the ſame Time.

The Time for ſowing this Seed, is commonly in *Auguſt*; but if it be ſown any Time before *Chriſtmas*, it will be Time enough.

The beſt Soil for this Seed, is good, freſh, light, ſandy Mould, mix'd with very rotten Neat's-dung, or Tanners-bark; with this you ſhould fill your Pots, Boxes, or Baſkets, in which you intend to ſow your Seeds; and having levell'd the Surface of the Earth very ſmooth, ſow your Seeds thereon, covering it very lightly with rotten willow Mould, then cover the Box, *&c.* with a Net or Wire, to prevent the Cats, Fowls, *&c.* from ſcratching out, or burying your Seeds too deep; let theſe Boxes, *&c.* be placed ſo as to receive half the Day's Sun, during the Winter Seaſon; but in the Beginning of *March*, remove them where they may have only the Morning Sun till Ten of the Clock; for your young Plants will now ſoon begin to appear, which, if expoſed to one whole Day's Sun only, will be all deſtroyed.

During the Summer Seaſon, in dry Weather, often refreſh them with Water; but never give them too great Quantities at once: In the *July* following, your Plants will be large enough to tranſplant, at which Time you muſt prepare a Bed, or Boxes, filled with the above-mention'd Soil, in which you may plant them about three Inches ſquare, and (if in Beds) you muſt ſhade them every Day, till they are thoroughly rooted, as alſo in very hot dry Weather; but if they are in Baſkets or Boxes, they may be removed to a ſhady Place.

When you have taken all your Plants which are now come up out of your Boxes or Pots, level the Earth gently again; for it often happens, that ſome of the Seeds will lie in the Ground two Years before they appear, eſpecially, if they were covered too deep when ſown.

The Spring following many of theſe Flowers will ſhew; when you may ſelect ſuch of them as have good Properties, which ſhould be removed each of them into a Pot of the ſame prepared Earth, and preſerved until the next Seaſon, at which Time you will be capable to form a Judgment of the Goodneſs of the Flower; but thoſe that produce plain-colour'd, or ſmall Flowers, ſhould be taken out, and planted in Borders in the Out-parts of the Garden, to make a Shew, or gather for Noſegays, *&c.* the others, which do not produce their Flowers the ſame Year, may be taken up, and tranſplanted into a freſh Bed, to remain till you ſee how they will prove.

The Manner of propagating theſe Flowers when obtained, is from Off-ſets, or Slips, taken from the old Roots in *April*, when the Flowers are in Bloom; theſe Off-ſets muſt be planted into ſmall Pots, filled with the ſame ſort of Earth, as was before directed for the Seedlings, and, during the Summer Seaſon, ſhould be ſet in a ſhady Place, and muſt be often refreſhed with Water, but in the Winter ſhould be ſheltered from the violent Rains; the Spring following, theſe young Plants will produce Flowers, tho' but weak; ſoon after they are paſt flowering, you muſt put them into larger Pots, and the ſecond Year they will blow in Perfection.

But in order to obtain a fine Bloom of theſe Flowers, you muſt obſerve the following Directions.

Firſt, Preſerve your Plants from too much Wet in Winter, which often rots and ſpoils them, but let them have as much free open Air as poſſible; nor ſhould they be too much expoſed to the Sun, which is apt to forward their budding for Flower too ſoon; and the froſty Mornings, which often happen in *March*, do thereby deſtroy their Buds, if they are not protected therefrom.

Secondly, In the Beginning of *February*, if the Weather is mild, you muſt take off the upper Part of the Earth in your *Auriculas* Pots, as low as you can without diſturbing their Roots, and fill up the Pots with freſh rich Earth, which will greatly ſtrengthen them for Bloom; as alſo prepare your Offſets for tranſplanting in *April*, by cauſing them to puſh out new Roots.

Thirdly, You muſt cover your Pots with Mats in froſty Weather, during this Time of their budding for Flower, leſt the ſharp Mornings blight them, and prevent their blowing.

Fourthly, when your Flower-ſtems begin to advance, and the Bloſſom-buds grow turgid, you muſt protect them from haſty Rains, which would waſh off their white mealy *Farina*, and greatly deface the Beauty of their Flowers; but at the ſame time, obſerve to keep them as much uncovered as poſſible, otherwiſe their Stems will be drawn up too weak to ſupport their Flowers, (which is often the Caſe when their Pots are placed under Walls) and give them gentle Waterings to ſtrengthen them; but let none of the Water fall into the Center of the Plant, or among their Leaves.

Fifthly, When your Flowers begin to open, you ſhould remove their Pots upon a Stage, (built with Rows of Shelves, one above another, and covered on the Top, to preſerve them from Wet; this ſhould be open to the Morning Sun, but ſhelter'd from the Heat of the Sun in the Middle of the Day;) in this Poſition they will appear to much greater Advantage, than when the Pots ſtand upon the Ground; for their Flowers being low, their Beauty is hid from us; whereas when they are advanced upon Shelves, we ſee them in a full View; in this Situation they may remain, until the Beauty of their Flowers are paſt; when they muſt be ſet abroad to receive the Rains, and have open free Air, in order to obtain Seeds, which will fail if they are kept too long under Shelter. When your Seed is ripe, obſerve to gather it when it is perfectly dry, and expoſe it to the Sun in a Window upon Papers, to prevent its growing mouldy, and let it remain in the Pods till the Seaſon for ſowing it.

AURICULA URSI MYCONI: *Vide* Verbaſcum.

AXIS *of a Plant.* *Axis* is properly that round, ſmooth Cylinder, about which a Wheel is turn'd; whence, by way of Metaphor, that long, round, ſmooth Part, placed in the Center in ſome Fruits, or Cat-tails, on Nut-trees, *&c.* about which the other Parts are diſpoſed, may be call'd the *Axis.* The *French* call it *Ame*, *Noyau*, or *Poinçon.*

AZEDARACH, the Bead-tree.

The *Characters* are;

It hath pennated Leaves ſomewhat like thoſe of the Aſh; the Flowers conſiſt of five Leaves, which expand in Form of a Roſe; in the Center of the Flower is a long fimbriated Tube, containing the Style; the Fruit is roundiſh and fleſhy, containing a hard furrow'd Nut, which is divided into five Cells, each containing one oblong broadiſh Seed.

The *Species* are;

1. AZEDARACH. *Dod.* The Bead-tree.
2. AZEDARACH *ſemper-virens & florens. Tourn.* The Bead-tree, which is always green and flowering.

The firſt Sort is propagated only by Seeds, (which may be obtained from *Italy* or *Spain*, where theſe Trees annually produce ripe Fruits in the Gardens where they are planted ; for it is not an Inhabitant of either of thoſe Countries :) the Seeds or Berries ſhould be ſown in Pots filled with good freſh light Earth, and plunged into a Hot-bed of Tanners-bark, where (if the Seeds are freſh) they will come up in about two Months Time : When the Plants are come up, you ſhould water them frequently, and begin to let them have a large Quantity of free Air, by raiſing the Glaſſes every Day ; and in *July* you ſhould expoſe them to the open Air, in a well ſhelter'd Situation, that they may be harden'd before Winter. In *October* you ſhould remove the Pots into the Conſervatory, where they ſhould be placed near the Windows, that they may enjoy free open Air, when the Weather is open ; for they don't care to be over-topp'd with other Plants. During the Winter Seaſon, you muſt refreſh them gently with Water ; but by no means repeat this too often, nor give them too much each time ; for their Leaves being fallen, they will not be in a Condition to throw off a Superfluity of Moiſture.

In *March* following, you may ſhake out your Plants from the Seed-pots, and divide them, planting each into a ſeparate ſmall Pot, filled with light freſh Earth, plunging them into a moderate Hot-bed, which will greatly promote their Rooting, and increaſe their Growth ; but you ſhould not draw them too much, but give them a large Share of Air, when the Weather is good ; and in *June* you ſhould remove them out into the open Air as before ; and during the three or four Winters, while the Plants are young, you muſt houſe them, to ſecure them from the Cold ; but when the Plants are grown pretty large and woody, they will endure to be planted in the open Air : The beſt Seaſon for this is in *April*, at which time you ſhould ſhake them out of the Pots, being careful not to break the Earth from the Roots, but only pare off with a Knife the Outſide of the Ball of Earth ; then open your Holes, and put in the Plant, cloſing the Earth to its Roots, obſerving, if the Weather is dry, to give it ſome Water, which ſhould be repeated twice a Week, until the Plants have taken Root : but you muſt obſerve to plant them on a dry Soil, and in a warm Situation, otherwiſe they will be liable to miſcarry in ſevere froſty Weather.

I have been informed, that there was formerly a large Tree of this Kind, in the Gardens of the Biſhop of *London*, at *Fulham*, which produced Flowers ſeveral Years ; but this, with many other valuable Trees, which were grown to a conſiderable Height in the ſame Gardens, have been long ſince demoliſhed.

At preſent I don't know of any of theſe Trees in *England*, which are arrived to any conſiderable Stature ; but I have tranſplanted one Tree, which is ſeven Years old, into the open Ground in the Phyſick-Garden, which I find reſiſts the Cold extremely well without any Shelter.

The outſide Pulp of this Fruit is in ſome Countries eat, but I don't find it is much commended ; but the Nut is by the *Monks* (and other Religious Perſons in *Roman* Catholick Countries) bored thro' with an Awl, and ſtrung as Beads, with which they ſay their *Pater-noſter*, which has occaſioned its being call'd the *Bead-tree*.

The ſecond Sort is at preſent very rare in *England*, being in very few Gardens ; this is much tenderer than the common Sort : It is propagated by Seeds, which muſt be ſown on a Hot-bed in the Spring ; and when the Plants are come up two or three Inches high, they muſt be tranſplanted each into a ſmall Half-penny Pot, filled with freſh light Earth, and plunged into a Hot-bed of Tanners-bark, obſerving to water and ſhade them, until they have taken Root, after which they muſt have Air and Water in Proportion to the Warmth of the Seaſon, or the Bed in which they ſtand. In this Bed they may remain until *Michaelmas*, when the Pots muſt be removed into the Stove, where they muſt have a moderate Share of Heat, and be often refreſhed with Water. The Spring following, they muſt be removed into larger Pots ; and if they are plunged into a moderate Hot-bed, to facilitate their taking Root, it will greatly promote their Growth ; but they ſhould not remain too long in this Bed, nor be too much drawn, which will weaken them. As the Summer advances, ſo they ſhould be inured by Degrees to bear the open Air, into which they ſhould be removed in *June*, obſerving to place them where they may be ſcreen'd from ſtrong Winds, and not too much expoſed to the Mid-day Sun. In this Situation they may remain till *Michaelmas*, when they muſt be removed into the Stove, and managed during the Winter Seaſon as was directed for the foregoing Winter ; and as the Plants grow large, they will be more hardy, when a ſmall Share of Heat will preſerve them in Winter, and in Summer they may be expoſed in a well ſhelter'd Situation. With this Management they will produce Flowers extremely well, and ſometimes they will fruit in *Europe*.

The common Sort has flower'd three or four Years ſucceſſively in the *Phyſick Garden* at *Chelſea* ; and the laſt Seaſon there was a good Quantity of Fruit on ſeveral Plants, but they were not perfected : but as theſe Plants are young, they can't nouriſh the Fruit ſo well as thoſe which are well grown ; ſo I doubt not but in a few Years they may produce ripe Fruit here.

AZEROLE, or L'AZAROLE : *Vide* Meſpilus.

B A

BACCA, *i. e.* a Berry, is a round Fruit, for the moſt part ſoft, and covered with a thin Skin, containing Seeds in a pulpy Subſtance ; but if it be harder, and covered with a thicker Skin, it is called *Pomum* ; *i. e.* an Apple.

BACCÆ, are ſmall roundiſh Fruits, that grow ſcattering upon Trees and Shrubs ; and in that are diſtinguiſh'd from *Acini*, which are Berries hanging in Cluſters.

Baccæ, in a more ſtrict Senſe, are uſed for a ſmaller thin-ſkinn'd Fruit, of a ſoft Pulp and Fleſh, including moiſt Seeds in a thinner Membrane.

BACCHARIS, Plowman's Spikenard. *Vide* Conyza.

BACCIFEROUS, [*Baccifer, Lat.* of *Bacca*, a Berry, and *fero, Lat.* I bear] is an Epithet added to the Names of any *Trees, Shrubs*, or *Plants*, that bear Berries, as *Bryony, Dwarf Honey-ſuckle, Lily of the Valley, Aſparagus, Butchers Broom, Night-ſhade, Solomon's-ſeal*, and many others.

BALAUSTIA. *Vide* Punica.

BALAUSTIUM, the Flower of the wild Pomegranate.

BALLOTE, [Βαλλωτὴ, ſo call'd by *Dioſcorides*, and is reckon'd among the Plants that were known to the Antients ; the Virtues of which *Dioſcorides* hath ſufficiently ſet forth. It is alſo call'd *Herba Jaculatoria*, becauſe it is good for thoſe wounded with Darts] Stinking black Horehound.

The *Characters* are ;

It hath Leaves like the Dead-Nettle, *the Flowers are produced in Bunches at the Joints of the Stalks, from the Pedicle of the Leaves, which have one ſingle Footſtalk, and ſtand but on one Side of the Stalks ; the Cup of the Flower is tubulous, and hath five Angles, divided into five Segments at the Top ; the* Galea *(or Creſt) of the Flower is hollow, and the Beard is cut into three Parts, the middle Part being broad, and ſhaped like a Heart ; each Flower is ſucceeded by four naked Seeds.*

We have two Varieties of this Plant growing wild in *England* ; which are,

1. BALLOTE. *Matth.* 825. *Marrubrium nigrum, ſive Ballote. J. B.* The ſtinking black Horehound.
2. BALLOTE, *flore albo. Tourn.* Stinking black Horehound, with white Flowers.

The firſt of theſe Plants is common upon moſt dry Banks near *London*, and is ſeldom ſuffer'd to have a Place in Gardens ; but this being a Plant ſometimes uſed in *Phyſick*, I thought proper to mention it in this Place : It may be eaſily propagated by either Seeds or Roots, but is very apt to increaſe too faſt in a Garden. This is the common *Black Horehound* of the Shops. The ſecond Sort is a Variety of the firſt, which is found ſometimes with the other wild.

BALM. *Vide* Meliſſa.

BALSAMINA, the Female Balſamine, *or* Balſam Apple.

The *Characters* are ;

It hath an anomalous Flower, which conſiſts of an unequal Number of Leaves, having ſometimes two, three, four, ſix, or more Leaves, with a Calcar *or* Spur *to the Flower : Theſe Flowers are ſucceeded by turbinated Veſſels, reſembling Pods, which, when ripe, upon the firſt Touch burſt, and caſt forth ſeveral roundiſh Seeds.*

The *Species* are ;

1. BALSAMINA *lutea, ſive Noli me tangere. C. B.* The yellow Balſamine, *or* Touch me not.

2. Balsamina *fœmina, flore purpureo.* The Female Balſamine, with purple Flowers.
3. Balsamina *fœmina, flore candido. H. L.* The white Female Balſamine.
4. Basamina *fœmina, flore rubro. H. L.* The Red Female Balſamine.
5. Balsamina *fœmina, flore majore candido. Tourn.* The large white-flower'd Balſamine.
6. Balsamina *fœmina, flore majore ſpecioſo. Tourn.* The large ſpecious-flower'd Female Balſamine.
7. Balsamina *fœmina, flore partim candido, partim purpureo.* The purple and white-ſtrip'd Balſamine.
8. Balsamina *fœmina, flore majore, elegantiſſime variegato.* The large-flower'd ſtrip'd Balſamine.
9. Balsamina *fœmina, flore majore pleno, elegantiſſime variegato.* The double large-flower'd ſtrip'd Balſamine, or immortal Eagle Flower.

The firſt of theſe *Species* is preſerv'd in Gardens, for the Diverſion it affords when the Seed Veſſels are ripe, by deſiring ignorant Perſons to gather them, who are ſurpriz'd to find, upon the firſt Touch, that the Pods fly to Pieces in their Hands: This Plant is very hardy in reſpect to Cold; and altho' it is Annual, yet, if ſuffer'd to caſt its Seeds, will come up every Spring without any Care; it delights beſt in moiſt ſhady Places, where, if it is not rooted out, it will multiply faſt enough.

The other Sorts are commonly rais'd on Hot-beds in the Spring, and afterwards planted into Pots or Borders, to adorn Court-Yards and Parterres. The ſecond, third, and fourth Sorts will come up in the common Ground, without any artificial Heat, and make ſtronger Plants than when rais'd in a Hot-bed, and ſtand longer in Flower, but the four laſt mention'd Sorts are much tenderer, and muſt be rais'd on a Hot-bed, and afterward planted in Pots, and ſet into a freſh Hot-bed to bring them forward (eſpecially the laſt Sort) which otherwiſe will not flower ſoon enough to produce ripe Seeds. There are two different Kinds of this large double-flower'd *Balſamine*, one is brought from the *Weſt-Indies*, by the Name of the *Cockſpur*; this is very apt to produce large ſtrong Plants, but rarely begins to flower till the End of the Summer, and then very often hath but ſmall Quantities of Flowers, and ſeldom produces ripe Seeds in *England*.

The other Sort is brought from *China*, by the Name of *Immortal Eagle Flower*; this Plant produces large beautiful double Flowers in great Quantities, and is one of the fineſt annual Plants we have, continuing a long Time in Flower (eſpecially if ſhelter'd from the Violence of Wind and Rain, both of which are great Enemies to this Plant); this Sort alſo ripens Seeds very well, but is apt to degenerate in a few Years with us to ſingle Flowers, and plain Colours.

Theſe Plants muſt be taken great Care of while young, and in the Hot-bed, particularly to give them as much free Air as poſſible, to prevent their running up too ſlender; nor muſt they have much Water, which often rots them at Bottom near the Surface of the Ground.

When you put theſe Plants into Pots, obſerve to chuſe ſuch as have clear ſpotted Stems, which always produce ſtrip'd Flowers, and thoſe with greeniſh Stems white Flowers, and the red Stems red Flowers: So that if you have Plants enough, you need only take the ſtrip'd ones. And in order to preſerve them from degenerating, you ſhould take off all ſingle or plain-colour'd Flowers from your Plants, and not ſuffer them to ſeed, by which means you will preſerve this beautiful Plant many Years longer than you otherways could.

BALSAMITA; Coſtus Hortorum, or Coſt-Mary.

The *Characters* are;

The Flowers are naked, and of a yellow Colour, growing in Umbels on the Top of the Stalks; the Leaves are intire, and are crenated about the Edges.

We have at preſent but one *Species* of this Plant in the *Engliſh* Gardens, which is;

Balsamita *major. Dod.* The large Coſt-Mary.

This Plant was formerly in greater Requeſt than it is at preſent; many People were fond of it in Soups with other Herbs; and its Uſe in Medicine is, at preſent, but ſmall: However, as it hath been an old Garden-Herb, I thought proper to mention it in this Place.

This Plant increaſes very faſt at the Root, and will grow in almoſt any Soil or Situation, ſo that whoever hath a mind to propagate it, need only plant a few Slips in the Spring or Autumn, in any common Border, and they will ſoon be furniſh'd with enough of it.

BAMIA MOSCATA. *Vide* Ketmia.

BANANA. *Vide* Muſa.

BANISTERA. *Houſt.*

This was ſo called from a famous *Botaniſt*, who loſt his Life in the Search of Plants in *Virginia*, ſo we have no *Engliſh* Name for the Plant.

The *Characters* are;

It hath a papilionaceous Flower, which is ſucceeded by one naked Seed, whoſe outer Membrane is extended into a winged Leaf, after the Manner of the Maple Seed.

The *Species* are;

1. Banistera *Americana ſcandens, foliis laurinis. Houſt.* Climbing Baniſtera with Laurel Leaves.
2. Banistera *Americana ſcandens, folio ſubrotundo, flore ex aureo coccineo. Houſt.* Climbing *American* Baniſtera, with a roundiſh Leaf, and a Flower from Gold to a ſcarlet Colour.
3. Banistera *Americana ſcandens, foliis citri, flore cæruleo ſpicato. Houſt.* Climbing *American* Baniſtera, with a blue ſpiked Flower.
4. Banistera *Americana ſcandens, foliis ſubrotundis, ſubtus pubeſcentibus. Houſt.* Climbing *American* Baniſtera, with roundiſh Leaves, of a whitiſh Colour underneath.
5. Banistera *Americana ſcandens, Pſeudoacaciæ folio, flore purpuraſcente. Houſt.* Climbing *American* Baniſtera, with a baſtard Acacia Leaf, and a purpliſh Flower.

Theſe Plants are all of them Natives in the warmeſt Parts of *America*, where they grow in the Woods, and twiſt themſelves round the Trunks of other Trees or Plants which grow near them, ſome of them growing four or five Feet high, and others will riſe to the Height of ten, twelve, or fourteen Feet; but muſt be ſupported by other Plants, for they do not grow erect.

The firſt, ſecond and third Sorts grow plentifully in the Woods in *Jamaica*, but the other two Sorts were collected by the late Dr. *William Houſtoun*, at *Carthagena* in the *Spaniſh Weſt-Indies*. Theſe Plants were called *Maples*, by Sir *Hans Sloane* and Father *Plumier*, from the Reſemblance which their Seeds have to thoſe of the *Maple*; but the Flower differing ſo remarkably from that of the *Maple*, the late Dr. *Houſtoun*, with good reaſon, ſeparated it from that *Genus*, and gave the Name of *Baniſtera* to them.

Theſe Plants may be propagated by Seeds which muſt be procured from the Places of their Growth. The ſureſt Method to ſucced, is to take the Seeds when they are fully ripe, and put them into a Tub of Earth or Sand, (for if they are brought over dry, they will not grow): when the Seeds arrive, they ſhould be immediately ſown in Pots filled light freſh Earth, and plunged into a Hot-bed of Tanners-bark, obſerving to keep the Earth conſtantly moiſt. Theſe Seeds will ſometimes lye ſeveral Months in the Ground, before they ſhoot, and at other times they will come up in a Month or five Weeks after ſowing. When the Plants begin to appear, they muſt be duly watered, and conſtantly kept clear from Weeds, and in warm Weather the Glaſſes ſhould be raiſed to admit freſh Air to the Plants. When they are about two Inches high, they ſhould be carefully ſhaken out of the Pots, and parted, planting each into a ſeparate ſmall Pot,and then plunged into the Hot-bed again, obſerving to water and ſhade them until they have taken new Root; after which time they muſt have a large Share of freſh Air in warm Weather, and muſt be frequently watered.

When the Plants have filled theſe ſmall Pots with their Roots, they ſhould be ſhaken out, and tranſplanted into Pots of a larger Size; and muſt be plunged into the Bark-bed again. When they are grown too tall to remain under the Glaſſes of the Hot-bed, they muſt be removed into the Bark-ſtove, and placed amongſt other tender exotick Plants, where if they thrive well, they will produce Flowers in two or three Years.

BARBA CARPA; *vide* Ulmaria.

BARBA JOVIS; Jupiter's Beard, *or* Silver Buſh.

The *Characters* are;

It hath pennated or winged Leaves; the Flowers are papilionaceous, and are ſucceeded by ſhort oval Pods, in which is, for the moſt part, contained one roundiſh Seed.

The *Species* are;

1. BARBA *Jovis, pulchre lucens. J. B.* The Silver Buſh; *vulgo.*

2. BARBA *Jovis, Hiſpanica, incana, flore luteo. Tourn. Spaniſh* Jupiter's Beard.

3. BARBA *Jovis, Caroliniana, arboreſcens, Pſeudoacaciæ foliis.* Baſtard Indigo *Incolis. Rand. Act. Phil. N.* 407. Baſtard Indigo, or *Carolina* Barba Jovis.

4. BARBA *Jovis, Africana, foliis viridibus pinnatis, flore cæruleo. Boerh. Ind.* The *African* Jupiter's Beard, with deep green Leaves and blue Flowers.

5. BARBA *Jovis Græca, linariæ folio argenteo ampliori, flore luteo parvo. Tourn. Cor. Greek* Jupiter's Beard, with a ſilver toad-flax Leaf, and ſmall yellow Flowers.

6. BARBA *Jovis Americana, annua, humilis, ramoſiſſima, floribus ſpicatis cæruleis.* Dwarf annual *American* Jupiter's Beard, with blue Flowers growing in a Spike.

7. BARBA *Jovis Americana, ſcandens, floribus cæruleis, ad alis foliorum conglobatis.* Climbing *American* Jupiter's Beard, with blue Flowers, coming out from the Wings of the Leaves.

8. BARBA *Jovis Americana, humilis, rotundifolia & villoſa, flore vario. Houſt.* Dwarf *Americana* Jupiter's Beard, with round hairy Leaves and a variable Flower.

9. BARBA *Jovis Cretica fruteſcens, incana, flore ſpicato purpureo amplo. Breyn. Prod.* 2. Shrubby Jupiter's Beard of *Crete*, with white Leaves, and large purple Flowers growing in a Spike.

The firſt of theſe Plants is very common in many Gardens; the ſecond is, at preſent, more rare with us; the third Sort was rais'd from Seeds ſent from *Carolina*, by Mr. *Cateſby*, and is by the Inhabitants made into a coarſe ſort of *Indigo*: This grows to be a large Shrub, and will reſiſt the Cold in the open Air very well; it is alſo a beautiful flowering Shrub, and for Diverſity merits a Place in Quarters of curious flowering Trees. This Plant will ſometimes produce ripe Seeds, by which means it may be eaſily propagated, and will alſo take Root by laying down the Branches in the Spring, which by the next Spring will be fit to tranſplant out: It delights in a ſandy dry Soil, and muſt have Room to ſpread its Branches, which extend a conſiderable Diſtance from the Stem: This Tree is very ſubject to ſplit if expos'd to ſtrong Winds.

The fourth Sort may be preſerv'd with the firſt and ſecond in a common Green-Houſe: They are not very tender, but require much free Air in good Weather, and frequent Waterings; They are all propagated by Seeds, which ſhould be ſown on a Hot-bed in the Spring, and tranſplanted into Pots of good light Earth (but not over-dung'd) and hous'd in Winter, with Myrtles, *&c.* and have a good Effect in adding to the Diverſity of the Green-houſe: Theſe Plants will ſometimes take Root from Cuttings; but as 'tis difficult to obtain Plants this Way, and the Seeds many times ripen very well with us, ſo I would recommend the raiſing them that Way, as the moſt ſure and expeditious.

The fifth and ninth Sorts were diſcovered by Dr. *Tournefort* in the *Archipelago*, and were brought to the Royal Garden at *Paris*, from whence they have been diſtributed to ſeveral of the *European* Gardens: Theſe may be propagated in the ſame Manner as the firſt Sort, and do require the ſame Culture.

The ſixth Sort is an annual Plant which was diſcovered by Dr. *William Houſtoun* at *Campechy*. This is only propagated by Seeds, which muſt be ſown very early in the Spring on a good Hot-bed, and when the Plants are come up two Inches high, they ſhould be each tranſplanted into a ſmall Pot filled with freſh light Earth, and plunged into a Hot-bed of *Tanners* Bark, obſerving to water and ſhade 'em until they have taken Root, after which time they ſhould have *Air* and *Water* in proportion to the Heat of the Seaſon. In *July* theſe Plants will flower, and if the Plants are preſerved either in the Stove, or under Glaſſes, they will perfect their Seeds in *September*, and ſoon after they will decay.

The ſeventh and eighth Sorts may be propagated from Seeds, which muſt be ſown as hath been directed for the ſixth; but theſe are abiding Plants, which muſt be placed in the Stove amongſt other *American* Plants, and will produce their Flowers every Year.

BARBAREA, or Winter-Creſs; *vide* Siſymbrium.

BARDANA, Burdock; *vide* LAPPA.

BAROMETER, [of βαρόμετρον, of βάρος a Weight or Burden, and μέτρον a Meaſure] is an Inſtrument or Machine for meaſuring the Weight of the Atmoſphere, or the minute Variations of the Weight or Preſſure of the incumbent Air, in order to determinate the Changes of Weather.

This Machine is founded on the *Toricellian* Experiment, ſo call'd from the Inventor *Toricellius*.

It conſiſts of a long Tube of Glaſs, hermetically ſealed at one End; and being fill'd with Quickſilver, is inverted ſo as to have one End of it immerg'd in a Baſon of ſtagnant Quickſilver, and the other hermetically ſeal'd, which is expos'd to the Preſſure of the outward Air: Out of which open End (after ſuch Immerſion) the Quickſilver in the Tube being ſuffer'd to run as much as it will into the ſtagnant Quickſilver, in which that Mouth or open End is immers'd; there is wont to remain a Cylinder of Quickſilver ſuſpended in the Tube, about twenty-eight, twenty-nine, or thirty Inches high, meaſuring from the Surface of the ſtagnant Quickſilver perpendicularly; but more or leſs within ſuch Limits, according as the Weight or Preſſure of the Air incumbent on the external ſtagnant Quickſilver expos'd to it, is greater or leſſer, leaving the upper Part of the Tube void, or at leaſt empty of common Air.

The *Phænomena* of the *Barometer* are various; and the Cauſes aſſign'd for them by ſeveral Authors as various; nor is the Uſe of it in predicting the Weather yet perfectly aſcertain'd.

The greateſt Height the Mercury has been known to ſtand at *London*, is thirty Inches three Eights, and its leaſt twenty-eight Inches: And though, as Mr. *Boyle* obſerves, the *Phænomena* of the *Barometer* are ſo very precarious, that it is very difficult to form any general Rules about the Riſe and Fall thereof, in that which ſeems to hold moſt univerſally, *viz.* That when the high Winds blow, the *Mercury* is the lower, ſometimes fail; yet the following Obſervations have been made by ſeveral Authors.

Dr. *Halley* obſerves, that in calm Weather, when the Air is inclin'd to rain, the Mercury is continually low; in ſerene good ſettled Weather, high.

That on great *Winds*, tho' unaccompany'd with Rain, the Mercury is loweſt of all, with regard to the Point of the Compaſs the Wind blows on; that, *cæteris paribus*, the greateſt Heights of the Mercury are on Eaſterly and North-eaſterly Winds; that after great Storms of Wind, when the Mercury has been low, it riſes again very faſt.

That in calm froſty Weather it ſtands high.

That the more northernly Places find greater Alterations than the more ſouthern; and that within the *Tropicks*, and near 'em, there is little or no Variation of the Mercury at all.

Dr. *Beal* obſerves, That *cæteris paribus*, the Mercury is higher in cold Weather than in warm, and uſually higher at Morning and Evening than at Mid-day.

That the Mercury is higher in ſettled and fair Weather than either a little before, or after, or in the Rain; and that it generally deſcends lower after Rain than it was before it: If it chance to riſe higher after Rain, it is generally follow'd by a ſettled Serenity.

That there are frequently great Changes in the Air without any perceptible Alterations in the *Barometer*.

As to the Predictions from the *Barometers*, Dr. *Halley* has found,

That the Riſing of the Mercury forebodes fair Weather after foul, and an Eaſterly or North-eaſterly Wind.

That the Falling of the Mercury portends Southerly or Weſterly Winds, with Rain, or ſtormy Winds, or both.

That in a Storm the Mercury beginning to riſe, is a pretty ſure Sign that it begins to abate.

Mr. *Patrick* obſerves, That the Falling of the Mercury in hot Weather preſages Thunder: That when foul Weather happens after the Fall of the Mercury, it ſeldom holds long: And the ſame is obſerv'd, if fair Weather ſucceeds preſently after its Riſe.

Dr. *Halley* alſo obſerves, as we have mention'd, That within the *Tropicks*, and near them, there is very little or no Variation of the Height of the Mercury at all.

Hence Mr. *Pointer* conceives, That the principal Cauſe of the Riſe and Fall of the Mercury is from the variable Winds which are found in the *Temperate Zones*, and whoſe great Unconſtancy here in *England* is moſt notorious.

A ſecond Cauſe he takes to be, uncertain Exhalation and Perſpiration of the Vapours lodging in the Air, whereby it comes to be at one time much more crowded than at another, and conſequently heavier; but this latter in a great meaſure depends upon the former.

And from theſe Principles he endeavours to explain the ſeveral *Phænomena* of *Barometer*.

1. The Mercury's being low, inclines it to Rain, becauſe the Air being light, the Vapours are no longer ſupported thereby, being become ſpecifically heavier than the Medium wherein they are floated; ſo that they deſcend towards the Earth, and in their Fall, meeting with other aqueous Particles, they incorporate together, and form little Drops of Rain; but the Mercury's being at one Time lower than another, is the Ef-

fect of two contrary Winds blowing from the Place where the *Barometer* ſtands; whereby the Air of that Place is carried both Ways from it, and conſequently the incumbent Cylinder of Air is diminiſh'd, and accordingly the Mercury ſinks: As for inſtance, if in the *German* Ocean it ſhould blow a Gale of Weſterly Wind, and at the ſame Time an Eaſterly Wind in the *Iriſh* Sea; or if in *France* it ſhould blow a Northerly Wind, and in *Scotland* a Southerly, it muſt be granted that that Part of the Atmoſpere impendent over *England* would thereby be exhauſted and attenuated, and the Mercury would ſubſide, and the Vapours which before floated in thoſe Parts of the Air, of equal Gravity with themſelves, would ſink to the Earth.

2. The greater Height of the *Barometer* is occaſion'd by two contrary Winds blowing towards the Place of Obſervation, whereby the Air of other Places is brought thither and accumulated; ſo that the incumbent Cylinder of Air being increas'd both in Height and Weight, the Mercury preſſed thereby muſt needs riſe and ſtand high, as long as the Winds continue ſo to blow; and then the Air being ſpecifically heavier, the Vapours are better kept ſuſpended, ſo that they have no Inclination to precipitate and fall down in Drops; which is the Reaſon of the ſerene good Weather, which attends the greater Heights of the Mercury.

3. The Mercury ſinks the loweſt of all by the very rapid Motion of the Air in Storms of Wind.

For the Tract of the Region of the Earth's Surface, wherein theſe Winds rage, not extending all round the Globe, that ſtagnant Air which is left behind, as likewiſe that on the Sides, cannot come in ſo faſt as to ſupply the Evacuation made by ſo ſwift a Current, ſo that the Air muſt neceſſarily be attenuated when and where the ſaid Winds continue to blow, and that more or leſs, according to their Violence: Add to which, that the horizontal Motion of the Air being ſo quick as it is, may, in all Probability, take off ſome Part of the perpendicular Preſſure thereof; and the great Agitation of its Particles, is the Reaſon why the Vapours are diſſipated, and do not condenſe into Drops, ſo as to form Rain, otherwiſe the natural Conſequence of the Air's Rarefaction.

4. The Mercury ſtands the higheſt upon an Eaſterly or North eaſterly Wind, becauſe in the great *Atlantick* Ocean on this Side the thirty-fifth Degree of North Latitude, the Weſterly and South-weſterly Winds blow almoſt always Trade; ſo that when-ever here the Winds come up at Eaſt and North-Eaſt, 'tis ſure to be check'd by a contrary Gale as ſoon as it reaches the Ocean; wherefore, according to what is made out in the ſecond Remark, the Air muſt needs be heap'd over this Iſland, and conſequently the Mercury muſt ſtand high, as often as theſe Winds blow.

This holds true in this Country; but is not a general Rule for others, where the Winds are under different Circumſtances: And he ſays, he has often ſeen the Mercury here as low as twenty-nine Inches upon an Eaſterly Wind, but then it blew exceeding hard, and ſo comes to be accounted for by what was obſerv'd upon the third Remark.

5. In calm froſty Weather, the Mercury generally ſtands high, becauſe, as he conceives, it ſeldom freezes but when the Winds come out of the *Northern* and *North-eaſtern* Quarters, or at leaſt unleſs thoſe Winds blow at no great Diſtance off:

For the Northern Parts of *Germany*, *Denmark*, *Sweden*, *Norway*, and all that Tract, from whence North-eaſtern Winds come, are ſubject to almoſt continual Froſt all the Winter, and thereby the lower Air is very much condens'd, and in that State is brought hitherwards by thoſe Winds; and being accumulated by the Oppoſition of the *Weſterly* Wind blowing in the Ocean, the Mercury muſt needs be preſs'd to a more than ordinary Height; and as a concurring Cauſe, the ſhrinking of the lower Parts of the Air into leſſer Room by Cold, muſt needs cauſe a Deſcent of the upper Parts of the Atmoſphere, to reduce the Cavity made by this Contraction to an *Equilibrium*.

6. After great Storms of Wind, when the Mercury has been very low, it generally riſes again very faſt: He ſays, he once obſerv'd it to riſe an Inch and a half in leſs than ſix Hours after a long continu'd Storm of South-weſt Wind.

The Reaſon is, becauſe the Air being very much rarefy'd by the great Evacuations that ſuch continued Storms make thereof, the neighbouring Air runs in the more ſwiftly, to bring it to an *Equilibrium*, as we ſee Water runs the faſter for having a great Declivity.

7. The Variations are greater in the more northerly Places, as at *Stockholm* greater than at *Paris*, [compar'd by Mr. *Paſcal*] becauſe the more northerly Parts have uſually greater Storms of Wind than the more *ſoutherly*, whereby the Mercury ſhould ſink lower in that Extreme; and then the northerly Winds bringing the condens'd and ponderous Air from the Neighbourhood of the Pole, and that again being check'd by a Southerly Wind, at no great Diſtance, and ſo heap'd up, muſt of Neceſſity make the Mercury, in ſuch caſe, ſtand higher in the other Extreme.

8. This Remark, that there is little or no Variation near the Equinoctial, does above all others confirm the Hypotheſis of the variable Winds being the Cauſe of theſe Variations of the Height of the Mercury; for in the Places above-named, there is always an eaſy Gale of Wind, blowing nearly upon the ſame Point, *viz.* E. N. E. at *Barbados*, and E. S. E. at St. *Helena*; ſo that there being no contrary Currents of the Air to exhauſt or accumulate it, the Atmoſphere continues much in the ſame State.

However, upon Hurricanes (the moſt violent of Storms) the Mercury has been obſerv'd very low; but this, but once in two or three Years, and it ſoon recovers its ſettled State, of about twenty-nine Inches and a half.

Dr. *Wallis* alſo made the following Obſervations on the *Barometer*:

That in thick foggy Weather, he found his Quickſilver to riſe, which he aſcrib'd to the Heavineſs of the Vapours in the Air.

That in Sun-ſhiny Weather it roſe, and commonly the clearer, the more; and this he thought might be imputed partly to the Vapours rais'd by the Sun, and making the Air heavier, increaſing the elaſtick or ſpringy Power of the Air: Which latter, he rather adds, becauſe he had ſometimes obſerv'd in Sun-ſhiny Weather, when Clouds had come for ſome conſiderable Time, as ſuppoſe an Hour or two, the Quickſilver has fallen; and then upon the Sun's breaking out again, it has riſen as before.

In rainy Weather it uſes to fall, the Reaſon of which is obvious, becauſe the Air is lightened by ſo much as falls, in ſnowy Weather likewiſe; but not ſo much as in Rains: And he had ſometimes obſerv'd it, upon a hoar Froſt falling in the Night.

In windy Weather he found it generally to fall, and that more univerſally, and more diſcernibly than upon Rain, which he attributed to the Winds moving collaterally, and thereby not ſuffering it to preſs ſo much directly downwards; (the like of which we ſee in Swimming, *&c.*) and that he had never found it lower than in high Winds.

That he had divers times upon diſcerning his Quickſilver to fall, without any viſible Cauſe at home, look'd abroad, and found (by the Appearance of broken Clouds, or otherwiſe) that it had rain'd not far off, tho' not with them, whereupon the Air being then lightened, the heavier Air with them, where it rained not, might have in Part diſcharg'd itſelf on that lighter.

Dr. *Liſter*'s Obſervations on the *Barometer* are as follow:

In *England*, in a violent Storm, or when the Quickſilver is at the very loweſt, it then viſibly breaks, and emits ſmall Particles (as he informs us he had more than once obſerv'd) which Diſorder he looks upon as a kind of fretting; and conſequently at all Times of its Deſcent, it is more or leſs upon the Fret.

In this Diſorder of the Quickſilver, he imagines it to have its Parts contracted; becauſe the Quickſilver them emits freſh Particles of Air into the Tube, which increaſing the Bulk of the Air, and conſequently its Elaſticity, the Quickſilver is neceſſarily depreſs'd thereby.

And that much Air is mix'd with it, appears from the Application of a heated Iron to the Tube, as is practis'd in the purging of it that Way.

Now when the Quickſilver riſes in the Tube (which it certainly does both in hot and froſty Weather) it may then be ſaid to be in a natural State, free, open, and expanded like itſelf, which it ſeems it ever is within the *Tropicks*, and with us only in very hot, and very froſty Weather.

But when it deſcends, it is then contracted, and as it were convuls'd, and drawn together; as it moſtly is in our Climate of *England*, and more or leſs (as we gueſs) in all Places on this Side the *Tropicks*.

Which Contraction plainly appears from the concave Figure of both Surfaces, not only in that of the Quickſilver in the Tube, but alſo, if well obſerv'd, in that which ſtagnates in the Pot or Diſh itſelf.

The Difficulty ſeems to lie in reconciling the ſame Effect of the Quickſilver's riſing in the Tube, from ſuch ſeemingly different Cauſes, as great Heat, and intenſe Froſt: And thoſe who ſhall aſſent in one Particular, and grant that Warmth is a probable Cauſe of its Reſtitution to its Nature, will yet be at a Stand how to imagine, that great Froſt ſhould likewiſe bring the Quickſilver nearer to its own Nature too.

To which he anſwers, that *Salts* liquified, will coagulate or cryſtalize, *i. e.* will return to their own proper Natures, both in Cold, and in Heat; and therefore, tho' moſt Men practiſe the ſetting them in a cool Cellar for that Purpoſe, yet ſome (as *Zwelfer*) adviſe, as the beſt Means to have them ſpeedily and fairly cryſtaliz'd, to keep them conſtantly in *Balno*.

Thus alſo the *Lympha* of the *Blood* becomes a Jelly, if it be ſet in a cool Place, and the ſame is inſpiſſated in like Manner by Warmth.

This Account of Dr. *Liſter*'s, however ingenious, is objected againſt, as coming far ſhort of accounting for the *Phænomena* of the *Barometer*, and that in ſome reſpects it contradicts them.

The Changes of the Weight of the Atmoſphere, muſt be laid down as the Cauſe of thoſe in the *Barometer*; but then whence thoſe Alterations ariſe in the Atmoſphere, will be no eaſy Matter to determine.

It is probable the Winds which are driven this or that Way, may have a great Share; and the Vapours and Exhalations ariſing from the Earth, alſo the Changes of the Air in the neighbouring Regions; and alſo the Flux and Reflux occaſioned in the Air by Moon.

Dr. *Halley* is of Opinion, the Winds and Exhalations are ſufficient, and on their footing, gives a very probable Rationale of the *Barometer*, the Subſtance of which is to the Purpoſe following:

1. The Winds muſt neceſſarily alter the Weight of the Air in any particular Country, and that either by bringing together or accumulating a greater Quantity of Air, and ſo loading the Atmoſphere of any Place; which will be the Caſe, as often as two Winds blow at the ſame Time, from oppoſite Points towards the ſame Point; or by ſweeping away Part of the Air, and removing ſome of the Load, give Room for the Atmoſphere to expand itſelf, which will be the Caſe, when two Winds blow at the ſame Time, and from the ſame Point oppoſite Ways; or in the laſt Place by cutting of the perpendicular Preſſure of the Atmoſphere, which happens as often as any ſingle Wind blows briſkly any Way; it being found by Experiment, that a ſtrong Blaſt of Wind, even made by Art, will render the Atmoſphere lighter, and accordingly the Mercury in a Tube, under which it paſſes, as well as in another at a Diſtance from it, ſubſides conſiderably.

2. The cold, nitrous Particles, and even Air itſelf condens'd in the Northern Parts, and driven elſewhere, muſt load the Atmoſphere, and increaſe its Preſſure.

3. Dry, heavy Exhalations from the Earth, muſt increaſe the Weight of the Atmoſphere, and heighten its Elaſtick Force, as the Specifick Gravity of *Menſtruums* are found to be increas'd, by diſſolv'd Salts and Metals.

4. The *Air* being render'd heavier from theſe and the like Cauſes, is thereby the more able to ſupport the Vapours, which being likewiſe intimately mix'd with it, and ſwimming every where equally throughout it, make the Weather ſerene and fair.

Again, the Air being made lighter from the contrary Cauſes, it becomes unable to ſupport the Vapours, wherewith it is replete; theſe therefore precipitating, are gathered into Clouds, and thoſe in their Progreſs coaleſce into Drops of Rain.

Theſe Things being obſerv'd, it appears pretty evident, that the ſame Cauſes, which increaſe the Weight of the Air, and make it more able to ſupport the Mercury in the *Barometer*, do likewiſe make a ſerene Sky, and a dry Seaſon; and the ſame Cauſes which render the Air lighter, and leſs able to ſupport the Mercury, do likewiſe generate Clouds and Rain.

Hence, Firſt, when the Air is lighteſt, and the Mercury in the *Barometer* loweſt, the Clouds are very low; and when after Rain the Clouds break, and a calm Sky again ſhines forth, being purg'd of its Vapours, it appears exceedingly bright and tranſparent, and affords an eaſy Proſpect of remote Objects.

Secondly, when the Air is heavier, and the Mercury ſtands higher in the Tube, the Weather is calm, tho' ſomewhat leſs clear, by Reaſon that the Vapours are diſpers'd every where equally; if any Clouds now appear, they are very high, and move ſlowly; and when the Air is heavieſt of all, the Earth is frequently found invelop'd in pretty thick Clouds, which appear to be formed out of the groſſer Exhalations, and which the Air is then able to ſuſtain, tho' a lighter Atmoſphere could not.

Thirdly, Hence it is, that with us the Mercury ſtands higheſt in the coldeſt Seaſons, and when the Wind blows from the North, and North-eaſt Corners: For in that Caſe there are two Winds blowing towards us at the ſame Time, and from oppoſite Corners, there being a conſtant Weſt Wind found in the *Atlantick* Ocean, in a Latitude that correſponds to ours. To this it may be added, that the cold condens'd Air of the Northern Parts is brought hither in a North Wind.

Fourthly, Hence in the Northern Regions, the Variation of the Mercury is more ſenſible than in the Southern ones; the Winds being found both more ſtrong, more frequent, more various, and more oppoſite to each other in the former than the latter.

Laſtly, Hence it is, that between the Tropicks, the Variation of the Mercury is ſcarce ſenſible; the Winds there being extremely gentle; and uſually blowing the ſame Way.

Now this Account, however well adapted to many of the particular Caſes of the *Barometer*, yet comes ſhort of ſome of the moſt principal, and the moſt obvious ones; and is beſides liable to ſeveral Objections.

For firſt, If the Wind were the ſole Agent in effecting theſe Alterations, we ſhould have no Alterations without a ſenſible Wind, nor any Wind without ſome Alteration of the Mercury; both which are contrary to Experience.

Secondly, If two Winds be ſuppos'd blowing from the ſame Place, *viz. London*, oppoſite Ways, *viz.* N. E. and S. W. there will be two others blowing from oppoſite Points, *viz.* N. W. and S. W. to the ſame Place; which two laſt will balance the firſt, and bring as much Air towards the Point, as the others ſwept from it. Or thus; in Proportion as the Air is carried off N. E. and S. W. the adjacent Air will crowd in from the other Points, and form a couple of new Currents in the Direction N. W. and S. E. to fill up the Vacancy, and reſtore the Equilibrium; this is a neceſſary Conſequence from the Laws of Fluids.

Thirdly, If the Wind were the ſole Agent, the Alterations in the Height of the Mercury would only be relative or topical; there would be ſtill the ſame Quantity ſupported at ſeveral Places taken collectively. Thus what a Tube at *London* loſt, another at *Paris*, or at *Piſa*, or at *Zurich*, &c. would gain at the ſame Time. But the very contrary is found true in Fact; for from all the Obſervations hitherto made, the *Barometers* riſe and fall together in ſeveral Parts of the Globe; ſo that it muſt be ſome Alteration in the abſolute Weight of the Atmoſphere, that accounts for the Riſe and Fall of the Mercury.

Laſtly, Setting all Objections aſide, theſe popular *Phænomena*, the Fall of the Mercury before, and the Riſe after Rain, are really unexplicable on the Foot of this Hypotheſis; for ſuppoſe two contrary Winds ſweeping the Air from over *London*, it is known, but few Winds, if any, reach above a Mile high; all therefore they can do, will be to cut off a certain Part of the Column of the Air over *London*: If the Conſequence of this be the Fall of the Mercury, yet there is no apparent Reaſon for the Rains following it: the Vapours indeed may be let lower, but it will only be till they come into an Air of the ſame ſpecifick Gravity with themſelves, and there they will ſtick as before.

M. *Leibnitz* has endeavour'd to ſupply the Defects of this Hypotheſis with a new one of his own. He aſſerts, That a Body immers'd in a Fluid, only weighs with that Fluid, while it is ſuſtain'd thereby; ſo that when it ceaſes to be ſuſtain'd, *i. e.* to fall, its Weight ceaſes to make a Part of the Fluid, which by this Means becomes lighter.

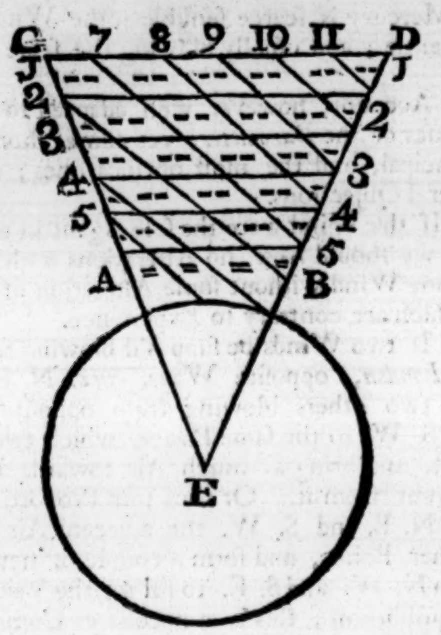
Thus, he adds, that the watery Vapours, while ſuſtain'd in the Air, increaſe its Weight; but when let fall, ceaſe to weigh along with it. Thus the Weight of the Air is diminiſh'd, and thus the Mercury falls, and Rain enſues.

But this Principle of M. *Leibnitz* is falſe, notwithſtanding the Experiment he brings to confirm it, as Dr. *Deſaguliers* has made appear by the Counter-experiment. For while a Body is immers'd in a Fluid, whether it be equal with it, or heavier, or lighter than the Fluid, whether it be at Reſt or in Motion, it adds to the Fluid a Weight of an equal Bulk of the Fluid, as follows from that Law in *Hydroſtaticks, that Fluids gravitate according to their perpendicular Altitudes.*

But however, if this Principle of M. *Leibnitz* were true, yet it is defective, and that in the ſame reſpect with Dr. *Halley*'s; nor would it account for the *Phænomena* more than the other.

For ſuppoſing the Vapours, by being condens'd, to be put in a Motion downward, and ſo ceaſing to gravitate with the Atmoſphere, they will therefore fall till they reach a Part of the Atmoſphere of the ſame ſpecifick Gravity with themſelves, and there they will hang as before: If the Mercury falls, it will be only during the Time of that Deſcent; for theſe once fix'd, the former Gravity is retriev'd; or were it not retriev'd, yet no Rain would enſue the Fall of the Mercury.

In order to account for theſe Variations of the *Phænomena* of the *Barometer*, Mr. *Chambers* advances what follows: Suppoſe any Number of watery Vehicles, *v. g.* a Million floating in any part of the Atmoſphere, over any determinate Portion of the Globe; as for Inſtance, over A B; if the upper Veſicles be condens'd by the Cold of the upper Regions, their ſpecifick Gravity will be increas'd, and they will deſcend; the horizontal Claſs 1 *v. g.* to 2, 2 to 3, *&c.* where meeting with other Veſicles, not yet precipitated, they will coaleſce or run into larger Veſicles, by the known Laws of Attraction.



Or, if we rather chuſe to have the Wind act, let it drive horizontally or obliquely: In the former Caſe, the Veſicles Claſs 8 will be driven againſt 9, that againſt 10, *&c.* or the oblique Claſs A 7 driven againſt 5, 8 againſt 4, *&c.*

By this means likewiſe will the Particles coaleſce, and form new and larger Veſicles as before; ſo that their Number, which before was a Million, will now be reduced, *v. g.* to an Hundred Thouſand: But by the ſame Coalition, whereby their Number is diminiſh'd, their ſpecifick Gravity is increaſed, *i. e.* they come to have more Matter in the ſame Space, or under the ſame Surface, as may eaſily be proved by Principles of Geometry.

For, in augmenting the Maſs of any homogeneous Body, the Increaſe of Surface does not keep pace with that of the Solidity; but that of the former is as the Square of the Diameter, and that of the latter, as the Cube of the ſame.

If then the Diameter of a Veſicle were 4, and its Surface and Maſs 24; after Coalition, if its Diameter be 6, its Surface or Bulk will be 54, and its ſolid Content 81. But ſince the ſame Quantity of Matter is now in a leſs Space, or under leſs Dimenſions, it will loſe of its Weight by the Reſiſtance of the Medium.

This is evident; for a Body immers'd in a Fluid loſes nothing of its Weight, but by the Friction of its Parts againſt thoſe of the Fluid; but the Friction is evidently as the Surface: Therefore, where the Surface is leſſen'd, the Reſiſtance muſt be ſo too. Conſequently the Veſicles, whoſe Gravity, before the Coalition, was equal to the Reſiſtance of the Medium, now that Reſiſtance is diminiſh'd, will deſcend, and that with a Velocity in a *Ratio* of the Increaſe of the Maſs to the Increaſe of the Surface.

In their Deſcent, as they ariſe at denſer Parts of the Atmoſphere, *v. g.* at 4, 5, *&c.* their Maſs and Surface again will be increas'd by new Coalitions; and thus by conſtant freſh Acceſſions, more than equal to the conſtant Reſiſtances, they will be enabled to purſue their Journey, thro' all the Stages of the Air, till they reach the Earth; their Maſſes exceedingly Magnified, and in the Form of Rain.

Now that the Vapours are got down, let us conſider how the *Barometer* muſt have been affected in their Paſſage, ere any of the Veſicles began to ſubſide, either from the Action of the Cold or of the Wind, they all floated in the Portion of the Atmoſphere A B C D, and all gravitated towards the Center E.

Here now each reſpectively reſiding in a Part of Medium, of the ſame ſpecifick Gravity with itſelf, will loſe as much of its Weight as is equal to that of a Part of the Medium of the ſame Bulk with itſelf, *i. e.* each will loſe all its Weight.

But then, whatever Weight each loſes, it communicates to the Medium, which now preſſes on the Surface of the Earth A B, with its own Weight, and that of its Veſicles conjointly.

Suppoſe then this united Preſſure keeps up the Mercury in the *Barometer*, at thirty Inches; by the Coalition of the Veſicles from the Cauſes aforeſaid, their Surfaces, and conſequently their Friction, are leſſen'd; they will therefore communicate leſs of their Weight to the Air, *i. e.* leſs than the Whole; and conſequently will deſcend with the Exceſs, *i. e.* with a Velocity equal to the Remainder, as before obſerved.

Now, as the Veſicles can act no otherwiſe upon the Surface of the Earth A B, but by the Mediation of the interjacent Air; in Proportion as their Action on the Medium is leſs, their Action on the Earth will be the leſs.

It is alſo evident, that the Surface of the Earth A B muſt be leſs preſſed than before; and that in Proportion as the Veſicles reſerve more of their Weight uncommunicated to the Medium, to promote their own Deſcent, *i. e.* in Proportion to the Velocity of the falling Veſicles, which is again in Proportion to their Bulks.

Thus, as the Veſicles deſcend, their Bulks continually increaſing the Friction, and therefore the Preſſure on the Earth, and laſtly, the Height of the Mercury, will continually decreaſe during the whole Time of the Fall.

Hence we ſee, both why the Veſicles, when once beginning to fall, perſevere; why the Mercury begins to fall at the ſame time; and why it continues and ceaſes to fall together with them: which were the great *Deſiderata* in the Philoſophy of the *Barometer*.

He ſays, he ſees but one Objection againſt this Theory, and that is, that the Veſicles being put in Motion, and ſtriking againſt the Particles of the Medium, and one another, with ſome Moment, will meet with a conſiderable Reſiſtance from the *vis inertiæ* thereof; by which means their Deſcent will be retarded, and the Preſſure of the Atmoſphere retriev'd; the *Impetus* of the moving Veſicles being ſuppoſed to compenſate for their Loſs of Surface.

Thus a heavy Body ſuſtain'd in a Fluid by a Hair, and moved up and down therein, preſſes more on the Bottom than when held at reſt; which additional Preſſure will be the greater, as the Velocity of the falling Veſicles is the greater, a greater Impulſe being requir'd to break thro' the *vis inertiæ* of the contiguous Particles, in a leſs Time than in a larger.

But there is both Reaſon and Experiment againſt this Objection; for beſides that the Velocity of the Veſicles in theſe Circumſtances muſt be very ſmall, and their Impulſe very inconſiderable; beſides that, the *vis inertiæ* of the Air muſt be very weak, by reaſon of its extreme Subtilty; and that it muſt be a very improper Vehicle to convey an Impulſe to a Diſtance, by reaſon of its Elaſticity.

We find, that even in Water (a groſs, unelaſtick Medium) and a piece of Lead, (a ponderous Body, which falls with a great Moment) that even here the Body, in its Deſcent thro' the Fluid, gravitates conſiderably leſs than when ſuſtain'd at reſt therein. In which the ſeveral Experiments of *Reaumur*, *Ramarrini*, and *Deſaguliers*, all agree.

Mr. *Patrick* gives us the following Rules and Obſervations for the Riſing and Falling of the Mercury, in order to foreknow the Weather by the *Barometer*.

It has been obſerv'd, that the Motion of the Mercury does not exceed three Inches in its Riſing or Falling in the *Barometer* of the common Form.

2. That its leaſt Alterations are to be minded, in order to the right finding of the Weather by it.

3. The Riſing of the *Mercury* preſages in general fair Weather, and its Falling foul, as Rain, Snow, high Winds and Storms.

4. In very hot Weather, the Falling of the Mercury foreſhews Thunder.

5. In Winter the Riſing of the Mercury preſages Froſt; and in froſty Weather, if the Mercury falls three or four Degrees, there will certainly follow a Thaw; but if the Mercury riſes in a *continued Froſt*, it will certainly ſnow.

6. When foul Weather happens *ſoon* after the falling of the Mercury, you may expect but little of it; and you may judge the ſame, when the Weather proves fair *ſhortly* after the Mercury has riſen.

7. When the Mercury riſes much and high in foul Weather, and continues ſo for two or three Days before the foul Weather is over, you may expect a *Continuance* of fair Weather to follow.

8. When the Mercury falls much and low in fair Weather, and continues ſo for two or three Days before the Rain comes, then you may expect a great deal of Wet, and probably high Winds.

9. The unſettled Motion of the Mercury, denotes uncertain and changeable Weather.

10. You are not ſo ſtrictly to mind the Words engraven on the Plates, tho' for the moſt part it will agree with them, as the Riſing and Falling of the Mercury; for if it ſtands at much Rain, and riſes up to changeable, it preſages fair Weather, altho'

altho' not to continue ſo long as it would have done if the Mercury were higher; and ſo on the contrary.

The following Rules and Obſervations have been made by another.

1. A ſtill Air, clear Sky, and the Mercury falling, with a froſty Morning in *October* and *November*, indicates much Rain or Snow about to ſucceed, eſpecially if the Wind be in any Point of the South.

2. If the Mercury riſes very ſuddenly and haſtily after Rain, it is generally a Sign that more Rain will ſucceed in a few Days, if the Wind be in any Point of the South.

3. If there be a compleat Circle or Halo at a Diſtance from the Body of the Moon (eſpecially if the Mercury fall) it is taken to be an infallible Sign of Rain or Snow.

4. If the Mercury falls when the Wind is full South, it is another never-failing Sign of Rain.

5. If the Mercury riſes not much, or continues low after the Fall of much Rain, the Wind being in any Point of the South, you may expect a fair and clear Sky, *ſtante cardine*.

6. If after Rain the Wind change into any Point of the North, with a clear and dry Sky, and the Mercury riſes, it is a certain Sign of fair Weather.

7. A Continuance of fair Weather, the Wind being in the North, and the Mercury high or riſing, is never ſucceeded by Rain, till the Wind changes into ſome Point of the South.

8. A Continuance of Rain from the South, is ſcarce ever ſucceeded by ſettled fair Weather, before the Mercury riſes much, and the Wind changes either to the Weſt, or ſome Point of the North.

9. The Reaſon why the *Barometer* ſeems to fail, in truth, is, that in Winter time, when the Wind is in the North, and the Mercury high, a deep Snow may fall without any Alteration of the *Barometer*; but in ſuch caſe it is only an Indication of very low Clouds, and a clear Atmoſphere above; the Conſequence of which is, the ſucceeding of a clear Air, and froſty Weather.

10. If in a Morning the Sky be red, with a ſudden cloudy Air, or the Mercury ſticks or ſtands with a concave Superficies, it is a ſure Sign of Rain or Snow to fall that very Day.

11. If the Mercury fall ſuddenly in Summer, eſpecially if the Wind be in the South, and the Air hot, heavy Rains, attended with Storm, Thunder, and Lightning, commonly ſucceed.

12. If the Mercury ſubſides when the Wind is in any Point of the North, Rain is to be expected, and a great deal of Rain if the Mercury continue to ſubſide.

13. If the Wind change into the Weſt, (as it commonly does) or ſome Point of the North; after there has been Rain in the South, and the Mercury riſes, the Rain yet falling, you may conclude that there will be but little Rain.

14. If in *fair Weather* the Mercury ſubſides very much, and continues to do ſo for two or three Days before Rain comes, you may expect high Winds, and a great deal of Wet.

15. If Rain follows *immediately* upon the ſubſiding of the Mercury, you need not fear *much Rain*.

16. It is remarkable, that moſt of the common and uſual Signs of Rain fall during the Seaſon of the Dog-days, and therefore are not to be regarded while the Mercury continues high.

N. B. The Mercury will fall for a Thaw, if it is not attended with Rain if the Wind change from the North to any Point of the South, becauſe a Thaw is always attended with a warm Miſt, and a very moiſt Air.

BARLERIA.

This Name was given to this Genus of Plants by Father *Plumier*, in honour of *Jacobus Barelier* of *Paris*, who was a famous Botaniſt. We have no *Engliſh* Name for it, but the Inhabitants of the Iſland of *Jamaica* call it *Snap-dragon*.

The *Characters* are;

It hath a perſonated Flower, conſiſting of one Leaf, whoſe upper Lip or Creſt is erect, but the under is divided into three Parts; from whoſe Empalement riſes the Pointal in the hinder Part of the Flower, which afterwards becomes a quadrangular oblong membranaceous Fruit, with one Capſule in which are lodged flat roundiſh Seeds.

The *Species* are;

1. BARLERIA *ſolani folio, flore coccinea. Plum. Nov. Gen.* Barleria with a Night-ſhade Leaf, and a ſcarlet Flower.

2. BARLERIA *aculeata, ſolani folio anguſtiore, flore cœruleo. Plum. Nov. Gen.* Prickly Barleria, with a narrow Night-ſhade Leaf, and a blue Flower.

The firſt of theſe Plants is very common in *Jamaica*, and ſeveral other Parts of the *Weſt-Indies*, but at preſent it is very rare in *England*. It grows to the Height of three or four Feet, and divides into many ſlender Branches, which are hoary. On the Top of the Branches come out the Flowers, which are of a fine red Colour, and ſhaped like thoſe of the *Antirrhinum* or Calves-ſnout; theſe Flowers are ſucceeded by quadrangular Seed-veſſels, which are about an Inch long, which contain a great Number of flat brown Seeds. Theſe Seeds when ripe, are caſt out with Violence on their Veſſels being touched.

The ſecond Sort is leſs common in *Jamaica* than the firſt, but it grows in great Plenty on ſome of the *French* Iſlands in *America*. This doth not riſe above two Feet high; the Leaves are narrower than thoſe of the former Sort, and the Flowers are of a fine blue Colour.

Theſe Plants are propagated by Seeds, which ſhould be carefully gathered when ripe, and muſt be ſown in Pots filled with light freſh Earth early in the Spring; theſe Pots muſt be plunged into a Hot-bed of Tanners-bark, and ſhould be frequently watered; but this muſt be done with great Caution, otherwiſe the Seeds may be waſhed out of the Earth. In about a Month's Time the Plants will begin to appear, when they ſhould be watered two or three times a Week, according as the Earth in the Pots ſhall become dry. In very warm Weather the Glaſſes of the Hot-bed ſhould be raiſed, in order to admit freſh Air to the Plants, as alſo to let out the Steam which may ariſe from the Bed: but if the Nights are cold, the Glaſſes ſhould be covered with Mats, to preſerve a gentle Warmth in the Bed; otherwiſe the Plants will ſtarve.

When the Plants are about an Inch high, they ſhould be carefully ſhaken out of the Seed-pots, and each planted into a ſeparate Half-penny Pot, filled with light freſh Earth, and then plunged into a moderate Hot-bed of Tanners-bark, obſerving to water and ſhade them until they have taken new Root; after which Time they ſhould have the Glaſſes of the Hot-bed raiſed every Day, in Proportion to the Warmth of the Seaſon, and the Heat of the Bed in which they are placed. You muſt alſo water them frequently, but you muſt obſerve to let the Water fall gently on them, otherwiſe you will deſtroy the Plants when they are ſmall.

In two Months after their removing (if the Plants have thriven) they will have filled the ſmall Pots with their Roots; therefore they ſhould be ſhaken out of thoſe Pots, and their Roots trimmed, and then put into Penny-pots, which ſhould be filled with light freſh Earth, and plunged into the Hot-bed again, where (if the Frames are deep enough to contain the Plants, without preſſing of their Tops) they may remain all the Summer Seaſon, obſerving to admit a large Share of freſh Air in warm Weather, as alſo to refreſh them with Water as often as they ſhall require it. With this Management the Plants will ſometimes produce their Flowers the ſame Seaſon, but they ſeldom produce good Seeds in this Climate the firſt Year; ſo that at *Michaelmas*, you ſhould remove ſome Plants of each Kind into the Bark-ſtove, where they ſhould be often refreſhed with Water during the Winter Seaſon, but it ſhould not be given to them in large Quantities. The Stove ſhould be kept to temperate Heat, which will preſerve theſe Plants thro' the Winter in good Health, and the following Summer they will produce Flowers and Seed in great Plenty.

BASELLA, or climbing Night-ſhade from *Malabar*.

The *Characters* are;

It hath an annual Root: The Stalks are climbing, and of a purple Colour: The Leaves are round, thick and ſucculent, and of a dark green Colour: From the Foot-ſtalk of the Leaves are produc'd Spikes of Flowers, which are Male and Female, in different Parts of the Spike: The Female Flowers are ſucceeded by flat Berries, in each of which is contained one hard Seed.

The *Species* are;

1. BASELLA. *Hort. Mal.*

2. BASELLA *flore albo, caule & foliorum pallide virentibus.* Climbing Night-ſhade from *Malabar*, with white Flowers, and pale green Stalks and Leaves.

3. BASELLA *Sinica, foliis & caulibus viridibus, minus ſucculentibus, fructu minori. Jeſſ.* Climbing *Indian* Night-ſhade, with green Stalks and Leaves, which are leſs ſucculent, and a ſmall Fruit.

Theſe Plants muſt be ſown early in the Spring upon a Hot-bed; and when they come up, muſt be planted into Pots of good freſh Earth, and ſet into a freſh Hot-bed, in order to bring them forward; and when grown too high to be contain'd under the Glaſſes, may be ſet into the Green-houſe, or in ſome well-defended Part of the Garden, that they may ripen their Seeds. There is no great Beauty in the Flower, but for the ſingular Appearance of theſe Plants, may deſerve a Place in all curious Collections of Plants.

The firſt Sort has thick ſtrong ſucculent Stalks and Leaves, which are of a deep purple Colour. The Plant requires to be ſupported; for it will climb to the Height of eight or ten Feet, and produce a great Number of Side-branches, which will twiſt round Stakes, and climb to a great Height, provided the Plants are preſerved in the Stove; for if they are expoſed to the open Air, they will not grow very large, nor will they perfect their Seeds, except it be in very warm Seaſons; but if they are placed in the Bark Stove, they will often live thro' the Winter, and produce great Quantities of Flowers and Seeds. The Flowers of this Plant have no great Beauty, but the Plant is preſerved for the odd Appearance of the Stalks and Leaves.

The ſecond Sort is exactly the ſame as the common Sort, excepting the Colour of the Leaves, Stalks, and Flowers; but I have obſerv'd it conſtantly retains the ſame Colour, ſo that I don't believe it to be an accidental Variety from Seeds; for from all the Seeds which I have ſown I never found any one of the Plants which differed from the Parent Plant. The laſt two Plants ſeldom continue more than one or two Years, but as they produce Seeds in Plenty, ſo they may be eaſily propagated.

The third Sort is leſs common in *England* than either of the former. I received the Seeds of this Plant from Dr. *Jeſſieu* of *Paris*, from which I have obtained a Variety with variegated Stalks and Leaves. This Sort will not perfect its Seeds ſo ſoon as either of the former Sorts, ſo muſt be placed in the Stove, where it will continue through the Winter, and produce ripe Seeds the ſecond Year. All theſe Sorts may be propagated by Cuttings, which ſhould be laid to dry a Day or two after they are taken from the Plants, before they are planted, that the Wound may heal, otherwiſe they will rot. Theſe Cuttings muſt be planted into Pots filled with light freſh Earth, and plunged into a moderate Hot-bed of Tanners-bark, where they will take Root in a Fortnight or three Weeks Time, when they ſhould be treated in the ſame Manner as the ſeedling Plants.

All theſe Plants will climb to a conſiderable Height, and ſend forth a great Number of Branches, ſo that they ſhould have a Place near the Back of the Stove, where they may be trained up to a Trelliſe, or faſtened to the Back of the Stove, otherwiſe they will twiſt themſelves about whatever Plants ſtand near them, which will make a very diſagreeable Appearance in a Stove, and alſo be very injurious to the other Plants; whereas, when they are regularly trained to a Trelliſe, they will have a good Effect in adding to the Variety.

From the Berries of the two firſt Sorts I have ſeen a beautiful purple Colour drawn, but when uſed for painting, did not continue very long, but chang'd to a pale Colour; tho' I believe there might be a Method invented, whereby this beautiful Colour might be fixed, ſo as to become very uſeful; for I have been aſſured, that the Juice of theſe Berries has been uſed for ſtaining of Callicoes in *India*.

BASILICUM or Baſil, *vide* Ocymum.

BASONS or Fountains, *&c.* which ſerve either for the Ornament or Uſe of Gardens, are made in divers Forms, ſome round, ſome oblong, or oval, others ſquare, octangular, *&c.* but their moſt common Form is circular; and, if the Ground will permit, the larger they are, the better: and when they exceed in Size, they are called Pieces of Water, Canals, Mirrors, Fiſh-ponds, Pools, and Reſervoirs.

In making theſe, Care ought to be taken to avoid both the Extremes, and not to make them either too big or too little; that a Water-work may not take up the beſt Part of a ſmall Spot of Ground; nor to make too little a *Baſon* in a large Spot. This muſt depend intirely on the Judgment of the Deſigner of the Garden.

Some would have the Size of a *Baſon* to be proportion'd to the *Jet d'Eau*, that the Water thrown up in the Air, may not, by being blown by the Air, be carried beyond the Edge of the *Baſon*, but all fall down without wetting the Walk.

As to the Depth of *Baſons*, it is uſually from two to three Feet: This Depth being ſufficient to ſecure the Bottom of the *Baſons* from Froſt, and to dip Watering-pots.

But if they are to ſerve for *Reſervoirs*, or to keep Fiſh in, then they may be made four or five Feet deep, which will both hold Water enough, and be deep enough for the Fiſh to breed in, and alſo to bear a Boat.

Deeper than this they need not be; and if they were deeper, they would be dangerous as to the drowning of Perſons, who might chance to fall in.

In making *Baſons*, great Care ought to be taken in making them at firſt; for the Water always naturally endeavouring to run away, and by its Weight and Preſſure in a *Baſon*, making its Way out at the leaſt Cranny, it will grow conſtantly bigger and bigger, ſo that if it be not well made at firſt, it will be very difficult to repair it.

Baſons are made either with *Clay*, *Cement*, or *Lead*; they are moſt uſually made of *Clay*: In making ſuch, at the marking out the Dimenſions, the Diameter ought to be four Feet bigger on each Side; yet the *Baſon* will not be the wider, for it will be taken up with the Walls on each Side; and the Clay Work, which is to fill the Space between the *Baſon*, muſt alſo be dug two Feet deeper than the Depth of the Water is deſign'd to be, becauſe it is to be laid over eighteen Inches thick with Clay, and ſix Inches with Gravel and Paving.

The Clay ought to be well wrought with the Hands and Water, and when it is ſpread, ſhould be trodden in with the naked Feet, that the Water of the *Baſon* may not dilute through it, and the Roots of any Trees that may grow near, may not penetrate into the outward Wall; which may be made of Shards, Rubble, or Flints, with Mortar made of the natural Earth, and is called the Ground-wall, becauſe 'tis only made to reſiſt the Preſſure of the Ground about it. The inward Wall ought to be made with good Rubble-ſtones, that will not ſcale and come off in Flaſhes in the Water; or elſe of Flints and Stones from the Hills, which will make durable Work, but will not look ſo neat as the pointed Rubble; and there ought to be laid here and there Stones, the Thickneſs of the Wall, to render it the more ſubſtantial.

The Method of making *Baſons* of *Cement* is as follows: After you have mark'd out the Dimenſions of the *Baſon* as before, if you inlarge it one Foot nine Inches, it will be ſufficient; and the ſame Depth deeper at the Bottom will be enough.

This being done, you muſt begin to back up and raiſe againſt the Ground; cut perpendicularly a Wall of Maſonry a Foot thick, which muſt go to the Bottom, and ſhould be built with Shards and Rubble-ſtones laid in Mortar of Lime and Sand.

When the Wall is finiſhed round the Circumference, then the Bottom is to be wrought a Foot thick with the ſame Materials; and then the ſolid Work or Lining of *Cement* is to be back'd up againſt the Walls nine Inches thick, including the Plaiſtering and inward Surface.

This Solid ought to be made of ſmall Flints, laid in Beds of Mortar made of Lime and *Cement*.

When this Solid is eight Inches thick, it ought to be plaiſter'd over the whole Surface of the Bottom with *Cement* well ſifted before it be temper'd with Lime; and with this it ſhould be wrought over ſmooth with the Trowel.

The Proportion of this *Cement* ſhould be two Thirds of *Cement* or powder'd Tile to one Third of Lime.

This *Cement* has the Property to harden ſo under Water, that it will be as hard as Stone or Marble, and the Body will be ſo ſolid as never to decay.

After the finiſhing of the *Baſon*, the Plaiſtering ſhould be for four or five Days ſucceſſively anointed over with Oil or Bullock's Blood, to prevent it from cracking or flawing; this being done, the Water ſhould be let into the *Baſon* as ſoon as may be.

Thoſe *Baſons* which are made of *Lead*, are to be thus wrought: The Out-lines ought to be inlarg'd one Foot of a Side, and digg'd half a Foot deeper than the *Baſon* is to be.

The Wall muſt be made a Foot thick, that it may be able to bear up againſt the Earth lying againſt it; but the Bottom will not require to be more than half a Foot thick.

Theſe Walls muſt be built with *Rubble*, laid in Mortar all of Plaiſter, becauſe the Lime will eat the Lead; and then the Lead muſt be laid on the Walls and Bottom, and be ſeam'd with Solder.

But *Baſons* of *Lead* are not much in Uſe, becauſe of their great Charge in making, and the Danger of the Lead being ſtolen.

Great Care ought to be taken to keep the upper Edge and Superficies of a *Baſon* upon a Level, that the Water may cover all the Walls equally.

As for the waſte Pipes of *Baſons*, whether at the Bottom or Superficies, they ought not to be made too ſmall, leſt they ſhould be choak'd, notwithſtanding the Cauls that are drawn before them.

When this waſte Water is only to be loſt in Sinks and common Sewers, it is carried away in Drains or Earthen Pipes; but when it ſerves to play the *Baſons* that lie below it, it muſt paſs thro' Leaden Pipes.

BAUHINIA; Mountain-Ebony, *vulgo*.

This Plant was ſo named by Father *Plumier*, in Honour of the two famous Botaniſts *John* and *Caſpar Bauhin*.

The *Characters* are ;

It hath a polypetalous anomalous Flower, conſiſting of five or more Leaves, which are diſpoſed on one Side ; from the Flower-cup ariſes the incurved Pointal, accompanied with ſeveral Stamina of the ſame Form, which afterward becomes a Pod incloſing kidney-ſhap'd Seeds.

The *Species* are ;

1. **BAUHINIA** *non aculeata, folio ampliori & bicorni. Plum. N. Gen.* Mountain-Ebony, *vulgo.*
2. **BAUHINIA** *aculeata, folio rotundo emarginato. Plum. N. Gen.* The *Indian* Savin Tree.
3. **BAUHINIA** *aculeata, folio rotundo emarginato, flore magno albo. Houſt.* Bauhinia with round Leaves, and large white Flowers.
4. **BAUHINIA** *flore luteo ſpicato, folio ſubrotundo bicorni. Houſt.* Bauhinia with a yellow ſpiked Flower, and a round Leaf divided at the Top.
5. **BAUHINIA** *non aculeata, folio nervoſo bicorni, floribus albicantibus. Houſt.* Smooth Bauhinia, with a nervous Leaf divided at the Top, and white Flowers.
6. **BAUHINIA** *non aculeata, folio ſubrotundo majore, rigido & bicorni, flore purpuraſcente. Houſt.* Smooth Bauhinia, with a large ſtiff Leaf divided at the Top, and a purpliſh Flower.
7. **BAUHINIA** *ſcandens & fruteſcens, folio ſubrotundo & bicorni, flore albo.* Shrubby climbing Bauhinia, with a round divided Leaf, and a white Flower.

The firſt Sort grows very plentifully on the Hills in every Part of the Iſland of *Jamaica* ; it is alſo a Native of the *Eaſt-Indies*, and is well figured and deſcribed in the *Hortus Malabaricus*. It grows to the Height of ſixteen or eighteen Feet, and produces Cluſters of party-coloured Flowers at the Extremity of the Branches, which are ſucceeded by long flat Pods, in each of which are contained four or five Seeds. The Wood of this Tree being very hard, the Inhabitants of the *Weſt-Indies* have given it the Name of *Mountain-Ebony*.

The ſecond Sort grows plentifully in the low Lands of *Jamaica*, and in ſeveral other Parts of the *Weſt* and *Eaſt-Indies* : this is alſo well figured and deſcribed in the *Hortus Malabaricus*. It grows to the Height of fifteen or ſixteen Feet, and produces large Spikes of beautiful yellow Flowers at the End of the Branches. The whole Plant, if bruiſed, emits a ſtrong Scent, ſomewhat like *Savin*, from whence the Inhabitants of the *Weſt-Indies* have given it the Name of *Indian Savin* Tree.

The third Sort grows at *Carthagena*, from whence I received Specimens of this Plant, collected by the late Dr. *William Houſtoun*.

The fourth, fifth, ſixth, and ſeventh Sorts have been collected in the *Spaniſh Weſt-Indies*, from whence I have receiv'd their Seeds, with fair Samples of the Plants dried ; ſome of them were collected by the late Dr. *Houſtoun*, and the others by Mr. *Robert Millar*, Surgeon.

Theſe Plants are only propagated from Seeds, which may be eaſily procured from the *Weſt-Indies*, which ſhould be ſown on a Hot-bed early in the Spring ; and when the Plants are come up two or three Inches high, they ſhould be tranſplanted, each into a ſeparate ſmall Pot, filled with freſh light Earth, and plunged into a Hot-bed of Tanners-bark, obſerving to water and ſhade them until they have taken Root ; after which they muſt have *Air* and *Water* in proportion to the Warmth of the Seaſon, and the Bed in which they are placed. When the Plants have quite filled theſe Pots with their Roots, they ſhould be removed out of theſe Pots, and after paring off the Roots on the Outſide of the Ball of Earth, they muſt be put into Pots a Size larger than thoſe, obſerving to fill the Pots with the ſame freſh Earth ; and if the Plants are too high to ſtand under the Glaſſes of the common Hot-bed, they muſt be plunged into the Bark-bed in the Stove, being careful to water them ſo often as they ſhall require it, and to let them have Air in Summer, in proportion to the Heat of the Seaſon ; but in the Winter they muſt be kept pretty cloſe ; the firſt Sort will not require ſo great a Share of Heat as the ſecond or third, both which are pretty tender Plants, and ſhould be placed near the Fire, or in a Stove, amongſt other of the moſt tender Plants. If theſe Rules be obſerved, and the Pots changed every Year, and new Earth applied to their Roots, they will make great Progreſs, and may be expected to flower in a few Years : but they muſt always be preſerved in the Bark-ſtove.

BAY. *Vide* Laurus.

BEANS.

There are four Sorts of *Beans* commonly planted in Gardens, *viz.* the ſmall *Liſbon*, the *Spaniſh*, the *Sandwich*, and *Windſor Beans*. The firſt and ſecond Sorts are uſually planted in *October* and *November*, under warm Walls or Hedges, to have them early ; where, if they ſtand thro' the Winter, they will produce *Beans* early in the Spring : Or they may be planted cloſe in Beds, in ſome Piece of Ground that is well defended from the *North* and *Eaſt* Winds ; and being arch'd over with Hoops or Withies, may be cover'd, in very hard Froſts, with Mats and Straw ; and in the Spring theſe Plants may be tranſplanted into warm Borders, by which means your Crop will be ſecured from Injuries of Froſt ; and if Care be taken in tranſplanting them, not to break their Roots, and alſo to water them, if the Seaſon proves dry, until they have taken freſh Root, they will bear as plentiful a Crop as thoſe which remain'd where they were at firſt Planted, with this Difference, that they will be a Fortnight later. The *Liſbon Bean* is chiefly preferr'd to the *Spaniſh* ; and the beſt Way is, to procure freſh Seeds from Abroad, at leaſt every other Year ; for they are ſubject to degenerate in a few Years in *England*, not in Goodneſs, but only in their Earlineſs.

The *Sandwich* and *Windſor Beans* are ſeldom planted before *Chriſtmas*, but eſpecially the *Windſor*, which is moſt ſubject to be hurt by Cold of any of the Kinds.

Theſe *Beans* ſhould have an open Expoſure, and require to be planted at a greater Diſtance than the two early Kinds ; for if they are planted in ſhady Places, or too cloſe, they will grow to a great Height, but ſeldom produce many *Beans*. The uſual Diſtance for theſe (if in an open Situation) is two Feet and an half Row from Row, and four Inches in the Rows ; but if the Place is cloſely ſurrounded with Hedges, Walls, or tall Trees, the Diſtance muſt be greater ; the Rows ſhould then be three Feet apart, and the *Beans* ſix Inches diſtant in the Rows. The *Sandwich Beans* being hardier than the *Windſor*, are uſually planted about *Chriſtmas*, to ſucceed the forward Crops ; and theſe, altho' at preſent but in little Requeſt, yet are very ſerviceable, being plentiful Bearers, and very little inferior either in Size or Goodneſs, to the *Windſor*.

In the Middle of *January*, if the Weather is open and good, you may plant your firſt Crop of *Windſor Beans*, which will ſucceed the *Sandwich*, and every three Weeks make a freſh Plantation, until the Middle of *May*, in order to preſerve a Succeſſion thro' the Seaſon : Indeed there are ſome People, who are very fond of *Beans*, which plant even in *June* ; but unleſs the Soil is very ſtrong and moiſt, or the Seaſon proves wet or cold, they ſeldom ſucceed well ; for in hot dry Weather, (which commonly happens in *July*) the Inſects infeſt theſe Plants very much, and often deſtroy them quite, ſo that I have known large Quarters of *Beans* to die away without producing one ſingle *Bean*. There are others who adviſe the cutting down of *Beans*, in order to cauſe them to produce freſh Shoots from the Bottom for a late Crop ; but this ſeldom anſwers the Trouble ; for they are liable to the above-mentioned Inconveniencies much more than a freſh-planted Crop.

There is an Error very common in moſt Gardeners, which I can't help mentioning, that is, their planting of *Beans* in the Alleys of their *Aſparagus-Beds*, which damages the two outer Rows of the *Aſparagus* much more than the Value of the *Beans*.

KIDNEY *or* FRENCH BEANS. *Vide* Phaſeolus.

BEAN-TREFOIL. *Vide* Cytiſſus.

BEAR's-EAR. *Vide* Auricula.

BEAR's-EAR SANICLE. *Vide* Verbaſcum.

BEAR's-FOOT. *Vide* Helleborus.

BECABUNGA, *or* Brook-lime.

This is a Sort of *Veronica*, or Water-ſpeedwel ; of which there are two Sorts, one with a long Leaf, and the other round : they are both very common in Ditches and watery Places, almoſt every-where in *England*.

BEE *or* GNAT-FLOWER. *Vide* Orchis.

BEECH-TREE. *Vide* Fagus.

BELL-FLOWER. *Vide* Campanula.

BELLADONA, Deadly Night-ſhade.

The *Characters* are ;

It hath a Bell-ſhaped Flower, conſiſting of one Leaf, which is divided into five acute Segments at the Top ; each of theſe Flowers is ſucceeded by a globular, ſoft Fruit, which is divided into two Cells, in which are lodged the Seeds.

The *Species* are ;

1. **Belladona** *majoribus foliis & floribus. Tourn.* The common Deadly Night-ſhade.

2. **Belladona** *minoribus foliis & floribus. Tourn.* Deadly Night-ſhade, with ſmaller Leaves and Flowers.

3. **Belladona** *fruteſcens, rotundifolia, Hiſpanica. Tourn.* Shrubby *Spaniſh* Deadly Night-ſhade, with a round Leaf.

4. **Belladona** *Americana fruteſcens, flore albo, nicotianæ folio. Plum. Cat.* Shrubby *American* Deadly Night-ſhade with a white Flower and a Tobacco Leaf.

The firſt Sort grows very common in many Parts of *England*, about Farmers Yards, and in ſhady Lanes, but is never kept in Gardens, unleſs in thoſe of Botaniſts ; nor indeed ſhould it be ſuffer'd to grow in any Places where Children reſort ; for it is a ſtrong Poiſon, and there have been ſeveral Inſtances, within a few Years paſt, of its deadly Quality, by ſeveral Children being kill'd with eating the Berries, which are of a fine black Colour, and about the Size of a black Cherry, and not unpleaſant to the Taſte.

Mr. *Ray* gives a good Account of the various Symptoms it produces, by what happen'd to a *Mendicant Frier* upon his drinking a Glaſs of Mallow Wine, in which was this Plant infuſed : In a ſhort Time he became delirious, ſoon after was ſeized with a grinning Laughter, after that, ſeveral irregular Motions, and at laſt a real Madneſs ſucceeded, and ſuch a Stupidity as thoſe that are ſottiſhly drunk have ; which, after all, was cured by a Draught of Vinegar.

There is alſo an Inſtance of the direful Effects of this Plant recorded in *Buchanan's* Hiſtory of *Scotland*, wherein he gives an Account of the Deſtruction of the Army of *Sweno*, when he invaded *Scotland*, by mixing a Quantity of the Juice of theſe Berries with the Drink which the *Scots* by their Truce were to ſupply them with, which ſo intoxicated the *Danes*, that the *Scots* fell upon them in their Sleep, and killed the greateſt Part of them, ſo that there were ſcarcely Men enough left to carry off their King.

The ſecond Sort is not ſo common in *England* as the firſt, but it is preſerved in Botanick Gardens for Variety.

Theſe Plants are both eaſily cultivated, by ſowing of their Seeds in the Spring on any Soil, or in any Situation, and when the Plants are come up, they may be tranſplanted into any abject Part of the Garden, where if they are ſuffered to remain, and drop their Fruit, they will fill the Ground with young Plants, and the old Roots will continue ſeveral Years. I have frequently ſeen theſe Plants growing out of the Joints of Walls, where they have endured the ſevereſt Froſt and the greateſt Drought for ſeveral Years. They do alſo grow equally well in low moiſt Soils ; ſo that there is no danger of their ſucceeding in any Place. The green Herb of theſe Plants is ſometimes uſed in cooling Ointments, as a Subſtitute for the *Garden Night-ſhade*, which being an annual Plant, is not to be had ſo early in the Seaſon as the other Herbs uſed in theſe Ointments, when the *Belladona* being in Perfection, is by many uſed.

The ſhrubby *Spaniſh* Kind is preſerved by the Curious in Botany, for the ſake of Variety, but there is very little Beauty in it. This will grow to the Height of eight or ten Feet, and have a ſtrong woody Stem. It may be propagated by planting the Cuttings in the Spring, upon a moderate Hot-bed, obſerving to water and ſhade them until they have taken Root ; after which time they muſt be inured to the open Air by degrees, and then they muſt be carefully potted, and placed in the Shade until they have taken new Root, when they may be ſet abroad with *Myrtles*, *Oleanders*, &c. and in Winter it muſt be removed into the Green-houſe, and placed amongſt the hardier Kinds of Exoticks. This plant produces Flowers every Year ; but I have not obſerved any Fruit produced in *England*.

The fourth Sort was diſcovered by Father *Plumier* in the *French* Settlements in *America* ; it hath alſo been found by Mr. *Robert Millar*, Surgeon, in the *Spaniſh Weſt-Indies* ; from whom I received the Seeds of this Plant. It is propagated by Seeds, which ſhould be ſown in Pots filled with light rich Earth, and plunged into a Hot-bed of Tanners-bark ; when the Plants are come up an Inch high, they ſhould be carefully tranſplanted, each into a ſeparate ſmall Pot, and plunged into the Hot-bed again, obſerving to water and ſhade them until they have taken Root ; after which Time, they ſhould have freſh Air admitted to them every Day, by raiſing of the Glaſſes ; and they muſt be conſtantly ſupplied with Water. During the Summer Seaſon they may remain in theſe Hot-beds, but in Winter they muſt be removed into the Bark-ſtove, where if they are kept in a temperate Degree of Heat, they will thrive extremely well, and produce their Flowers.

BELLIS, [is ſo call'd of *Bellus*, *Lat.* pretty, handſome, *&c.*] the Daizie.

The *Characters* are ;

It hath a perennial Root ; the Stalks are naked, and never branch out ; the Calyx (or Cup) of the Flower is ſcaly and ſimple, divided into many Segments, almoſt to the Footſtalk ; the Flowers are radiated ; and the Heads, after the Petals are fallen off, reſemble obtuſe Cones.

The *Species* are ;

1. **Bellis** *ſylveſtris, minor. C. B.* The common ſmall Daizie.

2. **Bellis** *ſylveſtris minor, flore miſto. C. B.* The ſmall ſtriped Daizie.

3. **Bellis** *hortenſis, flore pleno, magno vel parvo, rubro. C. B.* The red Garden Daizie, with double Flowers.

4. **Bellis** *hortenſis, flore pleno, magno vel parvo, albo. C. B.* The white double Garden Daizie.

5. **Bellis** *hortenſis, flore pleno, magno vel parvo, varie ex candido & rubro. C. B.* The double ſtriped Garden Daizie.

6. **Bellis** *hortenſis, prolifera. C. B.* The Garden childing Daizie, *commonly called*, The Hen and Chicken Daizie.

7. **Bellis** *hortenſis, floro pleno albo, in formam criſtæ galli figurato.* The white Cocks-comb Daizie.

8. **Bellis** *hortenſis, flore pleno rubro, in formam criſtæ galli figurato. Boerh. Ind.* The red Cocks-comb Daizie.

The firſt and ſecond Sorts are very common in the Meadows, almoſt in every Part of *England* : They are uſed indifferently in Medicine, being the ſame in all reſpects, except the Colour of the Flowers. This is alſo called *Conſolida minima*, or the *leaſt Conſound*.

The different Varieties of the Garden Daizies are propagated by parting their Roots in Autumn, and ſhould be planted in Borders of ſtrong Earth, which are expoſed to the Eaſt ; for the great Heats in Summer are very ſubject to deſtroy theſe Plants, if they are too much expoſed thereto. Theſe Plants are pretty Ornaments to a Garden in the Spring of the Year, and may be planted for Edgings in large rural Walks in Wilderneſſes, where the Soil is poor, which will prevent their ſpreading too much ; but in Parterre Gardens they ſhould only be planted in ſingle Roots in ſhady Borders, and every Year tranſplanted, which will preſerve them in their Colours, and keep them within Compaſs.

BELLIS MAJOR. *Vide* Leucanthemum.

BELLONIA.

This Plant was ſo named by Father *Plumier*, in Honour of the famous *Petrus Bellonius*, who has left many valuable Tracts on Natural Hiſtory, *&c.*

The *Characters* are ;

It hath a wheel-ſhaped Flower conſiſting of one Leaf, and divided at the Top into ſeveral Parts ; from whoſe Cup ariſes the Pointal, fixed in the middle of the Flower like a Nail : The Flower-cup afterward becomes a hard oval pointed Fruit, in which is contained many ſmall Seeds.

We have but one *Species* of this Plant, *viz.*

Bellonia *fruteſcens, folio meliſſæ aſpero. Plum. Nov. Gen.* Shrubby Bellonia, with a rough Balm Leaf.

This Plant is very common in ſeveral Parts of *America*, from whence I have received the Seeds ; which were collected by the late Dr. *William Houſtoun*.

It is propagated by Seeds, which ſhould be ſown early in the Spring, in a Pot filled with light freſh Earth, and plunged into a Hot-bed of Tanners-bark, obſerving to water it frequently, as the Earth appears dry, but you muſt be careful not to waſh the Seeds out of the Ground. When the Plants are come up half an Inch high, they ſhould be carefully tranſplanted into Pots filled with light freſh Earth, and plunged into the Hot-bed again, obſerving to water and ſhade them until they have taken Root ; after which Time they ſhould have Air admitted to them every Day when the Weather is warm, and they muſt be frequently watered. When the Plants have filled theſe Pots with their Roots, they ſhould be carefully ſhaken out of them, and their Roots trimmed, and then put into larger Pots filled with light freſh Earth, and then plunged into the Hot-bed again, obſerving to admit a larger Share of Air to them as the Weather becomes warmer, and as the Plants increaſe in Strength. In theſe Beds the Plants may remain during the Summer Seaſon,

ſon, provided the Glaſſes will admit of them to ſtand under them without preſſing their Tops; at *Michaelmas* the Plants ſhould be placed in the Stove, where they ſhould be frequently watered during the Winter, but it ſhould be given to them moderately at this Seaſon: The Stove in which theſe Plants are placed, ſhould be kept to temperate Heat, which is more agreeable to theſe Plants than a greater Warmth at that Seaſon; the ſecond Year theſe Plants will ſometimes flower, but they rarely produce good Seeds in this Climate; however, they may be propagated by Cuttings in the Summer Months, provided they are planted in light Earth on a moderate Hot-bed, and carefully watered and ſhaded until they have taken Root. Theſe Plants muſt be conſtantly kept in the Stove, and ſhould have a large Share of free Air in warm Weather, but if they are ſet abroad, they will not thrive in this Climate.

BELVEDERE: *vide* Chenopodium.

BENZOIN, The Benjamin-tree.

The *Characters* are;

From a Calyx, which conſiſts of four Leaves, are produced three ſmall Flowers, which have an oblong Tube; the upper Part, which is expanded, is divided into eight Segments; between theſe Segments are ſeveral ſhort Stamina *or Threads; and in the Middle of the Tube is the* Ovarium, *which becomes the Fruit.*

We have but one *Species* of this Plant in *England*, which is,

BENZOIN. *Boerh. Ind. Arbor Benzoinifera. Breyn. Prod.* The Benjamin-tree: *Vulgo.*

This Tree was brought from *Virginia* into *England* ſome Years ſince, and was by many People kept in Green-houſes as a tender Plant; but it hath been ſince planted into the open Ground, where it hath thriven mighty well, and is found hardy enough to reſiſt the ſevereſt Cold of our Winters: It commonly produces its Flowers early in the Spring, before the green Leaves appear, and many times will flower again in the Autumn, if the Seaſon proves mild; but I have not ſeen any Fruits produced in *England*.

This Tree is propagated by laying down the tender Branches in the Spring of the Year; which, by the ſucceeding Spring, will have made Roots ſufficient to be tranſplanted. The beſt Seaſon for this Work, is juſt before the green Leaves come out.

From this Tree, it was formerly ſuppoſed, that the *Gum Benjamin* was produced; but it is now generally otherwiſe believed; for that Gum is brought from the *Eaſt Indies*: nor is it certainly known from what Tree or Plant it is produced: And this Tree being a Native of the *Weſt Indies*, if any ſuch Gum had been produced from the Trees, it would have been more certainly known, and we ſhould have been furniſhed from thence with the Gum long before this Time.

BERBERIS, the Barberry *or* Pipperidge-Buſh.

The *Characters* are;

It is ſet with ſharp Prickles; the Leaves are oblong, and ſerrated on the Edges: the Flowers conſiſt of ſix Leaves, which expand in Form of a Roſe, and are of a yellow Colour: the Fruit is long, of an acid Taſte, and for the moſt part of a red Colour, and grows in Cluſters hanging down: the Bark of the Tree is whitiſh.

The *Species* are;

1. BERBERIS *Dumetorum. C. B.* The common Barberry.
2. BERBERIS *ſine nucleo. C. B.* Barberry without Stone.
3. BERBERIS *latiſſimo folio, Canadenſis. H. R. P.* The broad-leav'd *Canada* Barberry.
4. BERBERIS *fructu albo.* The white Barberry.

The firſt of theſe Sorts is very common in *England*, being often planted for Hedges; but the beſt Method to have large good Fruit, is, to plant them eight or ten Feet aſunder, keeping their Middles thin and free from dead Wood; but their Fruit being for the moſt part produced towards the Extremity of their Branches, you ſhould be ſparing in ſhortning them; and when this is done, 'it ſhould be at *Michaelmas*, when their Leaves begin to decay.

The ſecond Sort, I believe to be only an accidental Variety of the firſt; for young Plants taken from old Trees, which produce Fruits without Stone, are rarely found to prove right; and it hath been obſerved, that none but old Trees produce their Fruits ſo, nor are all the Fruits upon the ſame Tree without Stones. That Sort with white Fruit ſeems not to differ from the common, except in the Colour of the Fruit.

The *Canada Barberry* hath been of late Years introduced amongſt us. The Leaves of this Tree are larger than thoſe of the common Sort; and the Fruit of this Sort is black when ripe; but I have not ſeen any produced in *England*, altho' the Tree is equally as hardy as the common Sort.

Theſe are all propagated from Suckers taken from Roots of the old Plants, which generally furniſh them in abundance: Or they may be raiſed from Seeds, or by laying down their Branches, which will in one Year take ſufficient Root to be tranſplanted: They delight in a ſtrong loamy Soil, and may be planted either in *October* or *February*.

BERMUDIANA.

This Plant takes its Name from the *Bermudas Iſlands*, from whence the Seeds of the firſt Species was brought.

The *Characters* are;

It hath a Lilly Flower compoſed of ſix Petals, whoſe Empalement becomes a triangular Fruit, which opens in three Parts, and is divided into three Cells, which are filled with roundiſh Seeds.

The *Species* are;

1. BERMUDIANA *Iridis folio, fibroſa radice. Tourn.* Bermudiana with a Flower-de-lys Leaf and a fibrous Root.
2. BERMUDIANA *Palmæ folio, radice bulboſa. D. Lign. Tourn.* Bermudiana with a Palm Leaf and a bulbous Root.

The firſt Sort may be propagated by ſowing of the Seeds in the Spring on a moderate Hot-bed; and when the Plants are come up, they ſhould be tranſplanted into ſmall Pots, filled with light freſh Earth, and placed in a ſhady Situation until they have taken Root; after which time, they may be expoſed to the open Air in Summer; but in Winter they muſt be ſhelter'd from ſevere Froſt, to which if they are expoſed, it will deſtroy them. This Sort may alſo be propagated by parting of their Roots in the Spring; but they ſhould not be divided into too ſmall Parts, leſt it prevent their Flowering. This Plant produces ſmall blue Flowers in *June* and *July*, and in kindly Seaſons will perfect their Seeds in this Country.

The ſecond Sort never produces any Seeds in *England*, ſo can be only propagated by Off-ſets. This has a bulbous Root about the Size of the *Corn-flag*, but is not ſo flat. The Leaves of this Plant do die off in Winter, and in the Spring there are new ones put forth. This Plant is much tenderer than the former, and requires a Stove to preſerve it thro' the Winter: In Summer the Pots ſhould be placed in a Bark-bed, otherwiſe the Plants will not produce Flowers in this Country: In Winter they ſhould have very little Water given to them; for Wet will ſoon rot the Roots when their Leaves are decayed. There is no great Beauty in either of theſe Plants; but they are preſerved by the Curious, for Variety ſake.

BERNARDIA.

This was ſo named by the late Dr. *William Houſtoun*, in Honour of Dr. *Bernard de Jeſſieu*, Demonſtrator of Plants in the Royal Garden at *Paris*.

The *Characters* are;

It is Male and Female in different Plants; the Male Plants produce ſmall Katkins, which, when ripe, fall off; the Female-Plants have apetalous Flowers, which are ſucceeded by Tricoccos Fruits, reſembling thoſe of the Ricinus.

The *Species* are;

1. BERNARDIA *fruteſcens erecta, carpini folio, mas. Houſt.* Male upright ſhrubby Bernardia with an Hornbeam Leaf.
2. BERNARDIA *fruteſcens erecta, carpini folio, fœmina. Houſt.* Female upright ſhrubby Bernardia with an Hornbeam Leaf.
3. BERNARDIA *fruticoſa maritima repens, foliis ſubrotundis & ſubtus argenteis, mas. Houſt.* Male creeping ſhrubby Bernardia, with roundiſh Leaves, which are of a Silver Colour underneath.
4. BERNARDIA *fruticoſa maritima repens, foliis ſubrotundis & ſubtus argenteis, fœmina. Houſt.* Female creeping ſhrubby Bernardia, with roundiſh Leaves, which are of a Silver Colour underneath.

The two firſt Sorts were found by Doctor *Houſtoun* in *Jamaica*, where they are in great Plenty near the Sea and generally grow near each other; ſo that where-ever a Female Tree is found, there is rarely a Male wanting near it. Theſe uſually grow to the Height of eight or ten Feet, and divide into many Branches; the Flowers are produced at the Joints, near the Footſtalks of the Leaves.

The other two Sorts were found by Doctor *Houſtoun* at *La Vera Cruz*, where they grow on the Shore upon the Sand-banks; theſe ſeldom riſe above a Foot high, having many trailing Branches, which ſend forth Roots from their Joints, whereby they propagate themſelves.

Theſe Plants may be obtained from Seeds, which ſhould be brought over ſoon after they are ripe, and ſown in Pots filled with light freſh Earth, and plunged into a moderate Hot-bed of Tanners-bark, obſerving frequently to water them; when the Plants are come up, they ſhould be carefully tranſplanted into ſeparate Pots filled with light freſh Earth, and plunged into the Hot-bed again, obſerving to water and ſhade them until they have taken Root, after which Time they ſhould have Air and Water in proportion to the Warmth of the Seaſon, and the Heat of the Bed in which they are placed: in Summer they ſhould have a large Share of freſh Air in warm Weather, and ſhould be frequently watered; but in Winter they muſt be placed in a Stove, where they ſhould be kept in a moderate Heat, and muſt be frequently watered, but it ſhould not be given to them in large Quantities at that Seaſon. With this Management theſe Plants will thrive extremely well, and will produce their Flowers in this Climate, but they will rarely perfect their Seeds in this Country: Theſe Plants may be propagated by Cuttings, or laying down their tender Branches in the Spring; which, if duly watered, will take Root in three Months, when they may be cut off from the old Plants, and treated as thoſe raiſed from Seeds.

BESLERIA.

This Plant was named after *Baſilius Beſler*, an Apothecary at *Nuremberg*, who was the Author of a Book intituled *Hortus Eyſtetenſis*.

The *Characters* are;

It hath a Flower conſiſting of one Leaf, which is tubulous, and of an anomalous or perſonated Figure, having two Lips; from whoſe Cup ariſes the Pointal, which is fixed like a Nail in the hinder Part of the Flower, which afterward becomes a ſoft fleſhy oval-ſhaped Fruit, in which are many ſmall Seeds.

The *Species* are;

1. BESLERIA *meliſſæ Tragi facie. Plum. Nov. Gen.* Beſleria with the Face of Tragus's Balm.
2. BESLERIA *virgæ aureæ foliis, flore luteo minor. Plum. Nov. Gen.* Beſleria with Golden-rod Leaves, and a ſmall yellow Flower.
3. BESLERIA *virgæ aureæ foliis, flore luteo, major. Plum. Nov. Gen.* Beſleria with Golden-rod Leaves, and a large yellow Flower.
4. BESLERIA *ſcandens criſtata fructu nigro. Plum. Nov. Gen.* Climbing Beſleria with a black Fruit.

Theſe four Plants are common in the warm Parts of *America*, from whence the Seeds have been brought into *Europe*, and have been cultivated in ſome curious botanick Gardens. Theſe Seeds ſhould be ſown on a Hot-bed early in the Spring, and when the Plants are come up half an Inch high, they ſhould be each tranſplanted into a ſmall Pot filled with light freſh Earth, and plunged into a Hot-bed of Tanners-bark, obſerving to water and ſhade them until they have taken Root; after which Time they ſhould have Air and Water in proportion to the Warmth of the Seaſon, and the Heat of the Bed in which they are placed. When the Plants have filled theſe ſmall Pots with their Roots, they ſhould be ſhaken out of them, and their Roots trimmed, and then put into larger Pots filled with light freſh Earth, and plunged into the Hot-bed again; where they ſhould have a large Share of freſh Air in warm Weather, and muſt be frequently watered; with this Management theſe Plants will thrive very well in Summer, but in Winter they muſt be removed into the Stove, where they muſt be placed in a temperate Warmth, and ſhould be often watered: the ſecond Year theſe Plants will flower, and ſometimes they will perfect their Seeds in this Country; but they muſt be conſtantly preſerved in the Stove for they will not live in the open Air.

BETA, The Beet.

The *Characters* are;

It hath a thick fleſhy Root; the Flowers have no viſible Leaves, but many Stamina *or Threads, which are collected into a Globe; the Cup of the Flower is divided into five Segments; the Seeds are covered with a hard outer Coat, and grow too or three together in a Bunch.*

The *Species* are;

1. BETA *alba, vel palleſcens, quæ Cicla officinarum. C. B.* The common white Beet.
2. BETA *communis, ſive viridis. C. B.* The common green Beet.
3. BETA *rubra, vulgaris. C. B.* The common red Beet.
4. BETA *rubra, radice rapæ rotundæ. Boerh. Ind.* The Turnip-rooted red Beet.
5. BETA *rubra, major. C. B.* The great red Beet.
6. BETA *lutea, major. C. B. P.* The yellow Beet.
7. BETA *maxima, Helvetica, latiſſimo caule. Boerh. Ind.* The Swiſs *or* Chard Beet.

The two firſt mentioned are preſerved in Gardens for the Uſe of their Leaves in Pot-herbs, but at preſent they are not ſo much eſteem'd as they have been, and are but in few Gardens: The other Sorts are propagated for their Roots, which, in Winter, are boiled as Parſnips, *&c.* and ſerved up to Table, and are by many greatly eſteemed: The *Red Beet* is the moſt commonly cultivated, and is often uſed to garniſh Diſhes withal. The *Swiſs Beet* is by ſome very much eſteemed: the large flat Ribs of the Leaves are ſtew'd, and afterwards fry'd in Butter, which is accounted by many a delicate Diſh.

Theſe *Beets* are all propagated by ſowing their Seeds in *February* or *March*, in a deep looſe Soil, (but not over-dung'd) and muſt be houghed out after they are come up, ſo as to leave them ten or twelve Inches aſunder; for they ſpread very much, and if they have not Room, their Roots will be very ſmall. The Gardeners near *London*, in order to make the moſt of their Ground, ſow theſe *Beets* with *Carrots* upon the ſame Ground, and draw off their *Carrots* in the Summer-time for the Market, before the *Beets* have grown very large; and when the *Carrots* are gone, there will be Room for the *Beets* to grow, ſo that they have a double Crop: and if their *Beets* ſhould happen to fail, they plant a Crop of *Savoys* for the Winter, ſo that their Ground ſeldom lies idle.

BETONICA, [alias *Vetonica*, of the *Vetones*, an ancient People of *Spain*, who firſt found this Plant] Betony.

The *Characters* are;

The Leaves are green, rough, and crenated on the Edges; the Flowers are diſpoſed in a Spike; the upper Creſt of the Flower is advanced, and divided into two Segments; the Beard or lower Part of the Flower is divided into three; and the middle Segment is bifid; each Flower is, for the moſt part, ſucceeded by four naked Seeds.

The *Species* are;

1. BETONICA *purpurea. C. B.* The Common *or* Wood Betony.
2. BETONICA *alba. C. B. P.* Betony with a white Flower.
3. BETONICA *major, Danica. Park. Theat.* Greater *Daniſh* Betony.
4. BETONICA *minima, Alpina Helvetica. Park. Theat.* The leaſt Betony of the *Helvetian Alps*.
5. BETONICA *Alpina, incana, purpurea. Barell. Icon.* Hoary *Alpine* Betony, with purple Flowers.
6. BETONICA *Orientalis, folio anguſtiſſimo & longiſſimo, ſpica florum craſſiore. Tourn. Cor.* Eaſtern Betony, with a long narrow Leaf, and a thick Spike of Flowers.
7. BETONICA *rubicundiſſimo flore, Montis Aurei. H. R. Par.* Betony with a very red Flower, of *Mont d'Or* in *Auvergne*.
8. BETONICA *Orientalis, latifolia, caule brevi, flore maximo. Tourn. Cor.* Broad-leaved Eaſtern Betony, with a ſhort Stalk, and a very large Flower.
9. BETONICA *arvenſis, annua, flore ex albo flaveſcente. Tourn.* Annual Field Betony, with a yellowiſh white Flower.
10. BETONICA *Alpina, latifolia, major villoſa, flore luteo. H. R. Par.* Great broad-leaved hairy Betony of the *Alps*, with a yellow Flower.

The firſt Sort is very common in Woods and ſhady Places in moſt Parts of *England*: It may be propagated in ſhady Borders in a Garden, by either ſowing the Seeds in Spring, or by parting the Roots, which may be taken out of the Woods: The Soil ſhould be rather moiſt than dry, and not over-rich.

The other Sorts are all hardy Plants, and may be propagated by ſowing of their Seeds in the Spring, on a Bed of freſh Earth; and when the Plants are come up ſtrong enough to tranſplant, they ſhould be planted on a ſhady Border, where they will thrive, and the ſecond Year will produce Flowers, and perfect their Seeds. The ninth Sort is an annual Plant, which ſhould be ſown ſoon after the Seeds are ripe; for if they are ſown in the Spring, the Seeds do not come up ſo well, nor will the Plants produce good Seeds; ſo that, if the Seeds are permitted to ſhed, the Plants will come up and thrive without any farther Culture.

All theſe Sorts are preſerved by the Curious in Botany for Variety, but there are none of them uſed except the firſt Sort, which grows wild in Woods, and other ſhady Places, in divers Parts of *England*. This is greatly eſteemed as a vulnerary Herb; *Antonius Muſa* Phyſician to the Emperor *Auguſtus* wrote a whole Book concerning the Virtues of this Plant, from whence it came to be ſo much in Eſteem, that they have a Proverb in *Italy* to this Purpoſe; *Vende la Tonica, e compta la Betonica.* i. e. *Sell your Coat and buy Betony*; and when they would praiſe any Perſon very much, they ſay, he has more Virtue than Betony.

BETONICA AQUATICA: *vide* Scrophularia.

BETONICA PAULI: *vide* Veronica.

BETULA, The Birch-tree.

The *Characters* are;

The Leaves are like thoſe of the Poplar; *the Shoots are very ſlender and weak; the* Juli *or Catkins are produced at remote Diſtances from the Fruits on the ſame Tree; the Fruit becomes a little ſquamoſe Cone: the Seeds are winged; and the Tree caſts its outer Rind every Year.*

We have but one *Species* of this Tree in *England*, which is,

BETULA. *Dod.* The Birch-tree.

This Tree is propagated by Suckers taken from the Roots of old Trees, which may be tranſplanted either in *October* or *February*: It delights in a poor Soil, and will grow in either moiſt ſpringy Soils, or in ſtony or gravelly Marſhes, or Bogs: When the young Trees have been planted one Year, you ſhould (if deſigned for Under-wood) cut them down within ſix Inches of the Surface, which will cauſe them to ſhoot out ſtrong and vigorous Branches; but if they are deſigned for large Trees, it will be much better to let them ſtand two Years before you head them down; and when you do it, cut them within three Inches of the Ground, that their Stems may be ſtrait and handſome: but you muſt obſerve, when they begin to put out, whether they produce more than one Shoot; which if they do, you muſt rub off all but the ſtrongeſt and moſt convenient Shoot, which muſt be train'd up for a Stem.

The Timber of this Tree, tho' accounted the worſt of all others, yet is not without its various Uſes: the Turners often uſe it, to make Chairs, *&c.* and the Huſbandman, for making Ox-yokes; it is alſo planted for Hop-poles, Hoops, *&c.* but in Places within twenty Miles of *London*, it is kept often cut to make Brooms, and turns to great Account.

BIDENS, Water-hemp Agrimony.

The *Characters* are;

It hath a compound Flower, for the moſt part floſculous, conſiſting of many Florets, divided into ſeveral Segments, ſetting on the Embryo, and contained in the Flower cup: Sometimes there are alſo found Semi-florets: The Embryo afterward becomes a Seed, ending in Prickles.

The *Species* are;

1. BIDENS *folio tripartito diviſo. Cæſalp.* Water-hemp Agrimony, with a divided Leaf.
2. BIDENS *folio non diſſecto. Cæſalp.* Water-hemp Agrimony, with an undivided Leaf.
3. BIDENS *Canadenſis, latifolia, flore luteo. Tourn.* Broad-leaved Hemp-Agrimony of *Canada*, with a yellow Flower.
4. BIDENS *Americana, Apii folio. Tourn. American* Hemp-Agrimony, with a Smallage Leaf.
5. BIDENS *Indica, Hieracii folio, caule alato. Tourn. Indian* Hemp-Agrimony, with an Hawkweed Leaf, and winged Stalk.
6. BIDENS *trifolia, Americana, Leucanthemi flore. Tourn.* Three-leaved *American* Hemp-Agrimony, with a greater Daizie-flower.
7. BIDENS *Americana, ramoſiſſima, foliis gramineis, flore parvo luteo, Hieracium fruticoſum, anguſtiſſimis gramineis foliis, capitulis parvis. Sloan. Cat. American* branchy Hemp-Agrimony, with graſſy Leaves, and ſmall yellow Flowers.

The two firſt Sorts do grow wild in moiſt Places, and by the Sides of Ditches and ſtanding Waters, in moſt Parts of *England*, ſo are rarely permitted to have a Place in Gardens.

The third and fourth Sorts are Natives of the Northern Parts of *America*, where they are the moſt common Weeds: Theſe muſt be raiſed on a Hot-bed in the Spring, in order to bring the Plants forward, otherwiſe they will not perfect their Seeds in this Country.

The fifth, ſixth, and ſeventh Sorts were brought from the warmer Parts of *America*, ſo do require a greater Share of Heat to bring them to flower and ſeed in *England*. They are all annual Plants, ſo muſt be raiſed every Spring on a Hot-bed, and afterwards planted into Pots, and the two laſt ſhould be placed in a Bark-Bed, to bring them to flower; but the other three Sorts may be placed in the open Air, when the Plants have obtained ſufficient Strength, but muſt they be frequently water'd in dry Weather. There is no great Beauty in theſe Plants; but they are preſerved in many curious Gardens, for Variety.

BIFOLIUM, Twyblade.

This Plant grows wild in moiſt Meadows in divers Parts of *England*; it riſes in *May*, and flowers in *June*, and ſoon after dies away. This Plant is of no Uſe or Beauty.

BIGNONIA, [M. *Tournefort* call'd this Plant *Bignonia*, in Memory of Abbot *Bignon*, Librarian to *Lewis* XIV. King of *France*, he being a great Encourager of Learning:] The Trumpet-Flower *or* Scarlet Jaſmine.

The *Characters* are;

It hath a tubulous Flower, conſiſting of one Leaf, which opens at the Top like two Lips; theſe Flowers are ſucceeded by Pods, which are divided into two Cells, and contain ſeveral winged Seeds.

The *Species* are;

1. BIGNONIA *Americana, Fraxini folio, flore amplo Phœnicio. Tourn.* The Scarlet Trumpet-Flower: *Vulgo.*
2. BIGNONIA *Americana, capreolis donata, ſiliqua breviori. Tourn.* The four-leav'd Dwarf Trumpet-Flower: *Vulgo.*
3. BIGNONIA *Americana, arbor, flore luteo, Fraxini folio. Plum.* The large yellow Trumpet-Flower: *Vulgo.*
4. BIGNONIA *Americana, arbor, ſyringæ cœruleæ foliis, flore purpureo. Cateſb.* The blue Trumpet-Flower *or* Cattalpa.
5. BIGNONIA *Americana, arboreſcens, pentaphylla, flore roſeo, major, ſiliquis planis. Plum.* White Wood *or* Tulip-Flower: *Vulgo.*
6. BIGNONIA *ſcandens, tetraphylla, fructu maximo echinato. Houſt.* Climbing four-leaved Bignonia, with a large echinated Pod.
7. BIGNONIA *ſcandens, tetraphylla, flore racemoſo carneo. Houſt.* Climbing four-leaved Bignonia, with fleſh-colour'd Flowers growing in long Bunches.
8. BIGNONIA *Americana, foliis ſubrotundis glabris, fructu compreſſo orbiculato.* Trumpet Flower with ſmooth roundiſh Leaves, and round compreſſed Fruit.
9. BIGNONIA *Americana ſcandens, foliis pinnatis hirſutis, & marginibus ſinuatis, ſiliquis longiſſimis & anguſtiſſimis.* Climbing *American* Trumpet Flower, with winged hairy Leaves indented on their Edges, and long narrow Pods.
10. BIGNONIA *Americana ſcandens, triphylla & pentaphylla, lobis amplioribus mucronatis & ſerratis, ſiliquis longis compreſſis marginatis.* Climbing Trumpet-Flower, with three and five Leaves, which are large, pointed, and ſawed on their Edges, and long flat Pods which are bordered.
11. BIGNONIA *Caroliniana ſcandens, & ſempervirens, foliis anguſtis glabris, floribus luteis odoratis, ſiliquis breviſſimis.* Climbing *Carolina* Trumpet Flower, with narrow ſmooth Leaves, ſweet yellow Flowers, and ſhort Pods, commonly called yellow Jaſmine in *America*.

The Sort firſt mentioned is common in ſeveral curious Gardens near *London*, and is planted againſt Walls expoſed to the South Sun, where it thrives and produces large Quantities of Flowers annually; but it requires a great deal of Room, for it is a large Shooter; and the Flowers being always produced at the extreme Parts of the ſame Year's Shoots, if theſe are ſtopp'd, the Flowers are taken off; but in the Spring the young Branches may be ſhorten'd to three or four Eyes, as in Vines, and the ſmall weak Shoots taken out, leaving the large ones twenty Inches or two Feet aſunder: Theſe Branches ſtrike Roots into the Walls, by which they are ſecured, and require very little Aſſiſtance in nailing them up.

The ſecond Sort is of humble Growth, and is only propagated by laying down the Branches in Summer, when they are free of Growth, which in about ſix or eight Months will take Root, when they may be tranſplanted into Pots, and in Winter will require to be ſhelter'd with *Myrtles*, *&c.* where they may have a large Share of Air. In Summer they muſt be placed abroad, and treated as other hardy *American* Plants. This Plant doth not produce large Bunches of Flowers as the firſt, nor are they ſo deep colour'd.

There are two other Varieties of the firſt Sort, one of which has deeper colour'd Flowers, and the other has much ſmaller Leaves than the firſt: but they are both climbing Plants, and to be treated in the ſame Manner as was directed for the firſt. Theſe Plants will riſe to the Height of forty Feet, if they are permitted; ſo they are very proper to cover any high Wall or Building, to which they will faſten themſelves by ſtriking Roots into the Joints of the Wall.

The third Sort is ſcarce in *England* at preſent: this is a Tree of a large Growth in the warm Parts of *America*, but being tenderer than the other Sorts, requires to be kept in a Stove in *England*.

The fourth Sort was brought from the *Bahama* Iſlands by Mr. *Catesby*, a few Years ſince: It hath produced Flowers in *England*: It is very hardy, and grows to be a handſome upright Tree: The Leaves are very like thoſe of the *Lilac*, but ſomewhat larger. Theſe Trees are all of them propagated by laying their Branches, or from Suckers, (which in the two firſt Sorts are produced in great Plenty) and ſometimes the Cuttings will take Root, tho' not very often. The beſt Seaſon for tranſplanting theſe Trees, is in the Spring, after the cold Weather is paſt: They delight in a moiſt ſandy Soil.

The fifth Sort grows upright to a conſiderable Size in the *Weſt-Indies*, but in *England* it only makes a large Shrub, and produces Flowers annually in great Plenty. This Plant makes a beautiful Appearance in the Stove, the Leaves being large, of a thick Subſtance, and a ſhining green Colour: the Flowers are large, and have a ſweet ſcent, but are of a ſhort Duration. The Cuttings of this Plant will take Root, if they are taken off toward the latter End of *March*, before the Plants begin to ſhoot, and laid in the Stove two or three Days, to heal the wounded Part, before they are planted; for there is a large Quantity of a milky Juice in this Plant, which will occaſion the rotting of the Cuttings, if they are planted too green. Theſe Cuttings muſt be planted in Pots filled with freſh Earth, and plunged into a Bot-bed of Tanners-bark, obſerving to ſhade them in the Heat of the Day, and to refreſh them with Water; but it muſt not be given in too large Quantities, leſt it rot the Cuttings. It may alſo be propagated from Seeds, which may be obtained from *Jamaica* or *Barbadoes*; but it ſhould be brought over in the Pods, otherwiſe it will not keep, and ſhould be ſown as ſoon as poſſible, in Pots filled with freſh light Earth, and plunged into a moderate Hot-bed. When the Plants come up, they muſt be each tranſplanted into a ſeparate Pot filled with the ſame Sort of Earth, and plunged into the Hot-bed again, obſerving to water and ſhade them until they have taken Root; after which they muſt be treated in the Manner directed for the *Coffee-tree*, and other tender Plants, which are preſerved in the Bark-ſtove.

The ſixth and ſeventh Sorts are trailing Plants of lower Growth: Theſe were ſent from *Carthagena* by the late Dr. *Houſtoun*. Theſe may be propagated from Seeds, or by laying down of the Branches, which will take Root in three or four Months. Theſe ſhould be treated in the ſame Manner as the former Sort, and muſt be kept in the Bark-ſtove; but they do not require ſo much Heat in Winter, and in Summer ſhould have more Air; otherwiſe they will draw up weak. Theſe have not produced Flowers in *England* as yet; tho', from the Appearance of the Plants, we may expect them to flower very ſoon.

The eighth, ninth, and tenth Sorts were diſcovered by Mr. *Robert Millar*, Surgeon, at *Campechy*, from whence he ſent their Seeds, which have ſucceeded in the Phyſick-Garden at *Chelſea*, where theſe Plants are now growing.

All theſe Sorts may be propagated by Seeds, which ſhould be ſown in Pots filled with light freſh Earth, and plunged into a Hot-bed of Tanners-bark. Theſe Pots ſhould be frequently watered to keep the Earth moiſt, otherwiſe the Seeds will dry up, which will prevent their growing; when the Plants are come up, they ſhould be each tranſplanted into a ſeparate ſmall Pot filled with light freſh Earth, and plunged into the Hot-bed again, obſerving to water and ſhade them until they have taken freſh Root: after which Time they ſhould have Air and Water in proportion to the Warmth of the Seaſon, and the Heat of the Bed in which they are placed. As theſe Plants advance in Strength, ſo they ſhould be ſhifted into larger Pots; and when they are grown too tall to ſtand under the Glaſſes of the Hot-bed, they ſhould be removed into the Bark-ſtove, where they ſhould be kept in a moderate Heat, and muſt be frequently refreſhed with Water: with this Management the Plants will thrive extremely well, and in two Years many of them will produce their Flowers, but they rarely perfect their Seeds in this Country.

The eleventh Sort is very common in *South Carolina*, where it climbs on the Hedges, or whatever Plants grow near it; and in Summer produces fine Bunches of yellow Flowers, which have a moſt agreeable Scent. This may be propagated by Seeds as the former Sorts, and will thrive in a leſs Degree of Heat than either of them.

BIHAI.

This is the *American* Name of the Plant.

The *Characters* are;

It hath a tubulous Flower conſiſting of one Leaf, ſhaped almoſt like a Lily, and cut into two Parts; the Pointal and Stamina are included in two Leaves. The Pointal afterwards becomes a fleſhy three-cornered Fruit, containing three hard rough Seeds. To theſe Notes ſhould be added, many Flowers contained in a common Covering.

The *Species* are;

1. BIHAI *ampliſſimis foliis, florum vaſculis coccineis. Plum. Nov. Gen.* Bihai with large Leaves, and a ſcarlet Covering to the Flowers.

2. BIHAI *ampliſſimis foliis, florum vaſculis ſubnigris. Plum. Nov. Gen.* Bihai with large Leaves, and black Covering to the Flowers.

Theſe Plants are at preſent very rare in *Europe*. I received Seeds of the firſt Sort from *Panama*, which came up in the Phyſick-Garden at *Chelſea*; but the Plants have not produced any Flowers as yet.

They may be propagated by Seeds, which ſhould be ſown on a Hot-bed early in the Spring; and when the Plants are come up, they ſhould be each tranſplanted into a ſeparate Pot filled with light rich Earth, and plunged into a Hot-bed of Tanners-bark, obſerving to water and ſhade them until they have taken Root; after which time in warm Weather they ſhould have a large Share of freſh Air, and muſt be frequently watered. During the Summer Seaſon the Plants may remain in the Hot-bed; but in Winter they muſt be removed into the Stove, and placed near the Fire-place, that they may have a great Share of Heat, without which they will not live through the Winter in this Climate; they muſt alſo be frequently watered, but it ſhould not be given to them in too great Plenty in the Winter Seaſon, tho' in the Summer they will require a large Share of Moiſture: with this Management theſe Plants will produce their Flowers very well in this Climate.

BINDWEED. *Vide* Convolvulus.

BIRCH-Tree. *Vide* Betula.

BISLINGUA. *Vide* Ruſcus.

BISTORTA, [ſo call'd, becauſe the Root is turn'd or wreath'd into various Rings or Spires] Biſtort *or* Snake-weed.

There are three or four Varieties of this Plant which are found wild in *England*; but as they are ſeldom planted in Gardens, ſo I ſhall paſs them over with only mentioning the common Sort which is uſed in Medicine.

BISTORTA *major, radice minus intorta. C. B.* The common great Biſtort *or* Snake-weed.

This Plant flowers in *May*, and if the Seaſon proves moiſt, will continue to produce new Spikes of Flowers till *Auguſt*. It may be propagated by planting the Roots in a moiſt ſhady Border, either in Spring or Autumn, and will ſoon furniſh the Ground with Plants; for it greatly increaſes by its creeping Roots.

BIVALVULAR, or *Bivalve*, [of *Bivalvis*] Huſk, is one that opens or gapes the whole Length, like a Door that opens in two Parts.

BLADDER-NUT. *Vide* Staphyllodendron.

BLATTARIA, [takes its Name of *Blatta*, *Lat.* a Moth; becauſe, ſays *Pliny*, where-ever it is laid, Moths gather to it] Moth-Mullein.

The *Characters* are;

The Leaves are placed alternately upon the Branches; the Cup of the Flower conſiſts of one Leaf, which is divided into five Segments; the Flowers conſiſt of one Leaf, which ſpreads open, and is divided alſo into five Segments; they are produced in long Spikes, and are ſucceeded by round Veſſels, which are divided into two Cells, and contain many ſmall Seeds in each.

The *Species* are;

1. BLATTARIA *lutea.* *J. B.* The yellow Moth-Mullein.
2. BLATTARIA *alba.* *C. B.* The white Moth-Mullein.
3. BLATTARIA *flore roſeo.* *Boerh. Ind.* The Roſe-colour'd Moth-Mullein.
4. BLATTARIA *purpurea.* *C. B.* The purple Moth-Mullein.
5. BLATTARIA *perennis, folio verbaſci, flore luteo amplo. Mor. Hiſt.* The perennial Moth-Mullein, with large yellow Flowers.

There are ſeveral other Varieties of this Plant, which are preſerv'd in the curious Gardens of the Botaniſts; but theſe mention'd are ſome of the moſt beautiful, and are worthy preſerving in all curious Gardens, except the firſt, which is a ſpontaneous Plant in *England*; for which Reaſon I placed it here in the Front to introduce the reſt.

The three firſt mention'd are biennial Plants, never ſtanding more than two Years, and ſometimes but one: They muſt be ſown in the Spring; and when they are come up, may be tranſplanted where they are to remain for good. If any of theſe Plants ſhoot up to flower the firſt Year, the Winter will deſtroy them; but thoſe that are backward will endure our ſevereſt Winters, provided they are planted on a dry rubbiſhy Soil, and the next Spring will flower and produce good Seeds. When theſe Plants are in Flower, they perfume the Air, and have a Scent ſomewhat reſembling Violets at a ſmall Diſtance.

The fourth and fifth Sorts are Perennials, their Roots abiding ſeveral Years in the Ground: Theſe are alſo raiſed by ſowing their Seeds: for their Roots do ſeldom part well, and the often removing them prevents their flowering ſtrong. All theſe Sorts delight in a dry, poor, ſtony, or gravelly Soil, and are often found growing upon old Walls and Buildings.

BLIGHTS.

There is nothing ſo deſtructive to a Fruit-Garden as *Blights*; nor is there any Thing in the Buſineſs of Gardening which requires more of our ſerious Attention, than the endeavouring to prevent or guard againſt this great Enemy of Gardens.

In order therefore to remedy this Evil, it will be neceſſary firſt to underſtand the true Cauſes of *Blights:* And altho' many curious Perſons have attempted to explain the Cauſes of them, yet very few of them have yet come near the Truth, except the Reverend and learned Dr. *Hales*, who hath in his curious Book, intituled, *Vegetable Staticks*, given us ſome accurate Experiments upon the Growth and Perſpiration of Plants; together with the various Effects the Air hath upon Vegetables; that by carefully attending thereto, together with diligent Obſervations, we need ſeldom to be at a Loſs how to account for the Cauſes of *Blights*, whenever they may happen.

But here I can't help taking Notice of the ſeveral Cauſes of *Blights*, as they have been laid down by ſome of our modern Writers on Gardening; together with their various Methods preſcribed to prevent their Deſtruction of Fruits, *&c.*

Some have ſuppoſed, that *Blights* are uſually produced by an Eaſterly Wind, which brings vaſt Quantities of Inſects Eggs along with it from ſome diſtant Place, which being lodged upon the Surfaces of the Leaves and Flowers of Fruit-Trees, cauſe them to ſhrivel up and periſh. To cure this Diſtemper, they adviſe the burning of wet Litter on the Windward Side of the Trees, that the Smoak thereof may be carried to them by the Wind, which they ſuppoſe will ſtifle and deſtroy theſe Inſects, and thereby cure the Diſtemper.

Others direct the Uſe of Tobacco-duſt; or to waſh the Trees with Water wherein Tobacco-ſtalks have been infuſed for twelve Hours; which, they ſay, will deſtroy theſe Inſects, and recover the Trees: And Pepper-duſt ſcatter'd upon the Bloſſoms of Fruit-Trees, has been recommended as very uſeful in this Caſe: And there are ſome that adviſe the pulling off the Leaves of the Tree, as the beſt Remedy, when they are ſhrivell'd up and wither, and to cut off the ſmaller Branches, when they produce crooked and unnatural Shoots, and to ſprinkle the Tree with a Watering-Pot, or a Hand-Engine.

Theſe Conjectures concerning *Blights*, how ſpecious ſoever they may appear at firſt Sight, yet, when duly conſider'd, will be found far ſhort of the true Cauſe, as will hereafter be ſhewn.

Some there are who imagine the moſt deſtructive *Blights* which attend Fruit-Trees, are produced by ſmall Showers of Rain, or white Hoar-froſts falling upon the Bloſſoms of Fruit-Trees, which being ſucceeded by cold North or Eaſterly Winds, or froſty Mornings, are the Occaſion of the frequent *Blights* which happen in the Spring Seaſon: To prevent this Miſchief, it hath been recommended by a late Author, to build new Walls; in which, at every third Courſe of Bricks, ſhould be laid a Row of plain Tiles, which ſhould project forward, and hang over the Plain of the Wall above an Inch and an half, to carry off the perpendicular Dews and Rains, leaving Room, at Diſtances, between the Tiles to carry up the Branches of the Tree. This Method is ſo poſitively laid down, as a great Advantage for the more certain obtaining of Fruit, by a Gentleman whoſe Profeſſion ſhould incline him to Modeſty, eſpecially when he was not ſure of his Facts, that I can't paſs it over without ſome Animadverſions.

1. He ſays, That theſe horizontal Shelters will be of Advantage, even in the moſt difficult Years, to preſerve the Fruit, ſo that a good Quantity of it may be almoſt depended on, from ſuch Branches and Bloſſoms as were ſhelter'd by the Tiles, as he himſelf had often experienced.

As to this firſt Article, I need ſay no more than what Mr. *Collins* hath already written, *viz.* That this Reverend Gentleman acknowledged to him, at leaſt a Year after his Book was printed, that he never had any Walls of that Kind; but that, a few Days before this Viſit, he had ſtuck a few Pieces of Tiles and Oyſter-ſhells into a Mud-wall at particular Places, over ſome Bunches of Bloſſoms, with Mortar, which was not dry at that Time; which he declared was his firſt Eſſay: Now how a Gentleman of his Character can anſwer the adviſing of Perſons to put themſelves to ſuch an extravagant Expence as the building of new Walls for Fruit, with an Aſſurance of Succeſs, when it was only a ſimple Imagination of his own, without ſo much as a ſingle Experiment to ſupport it, I am wholly at a Loſs to know.

But let us proceed to his ſecond Article, in which he ſays, That Fruit thus ſhelter'd, will be larger, better fed, and finer taſted, than thoſe on the ſame Tree, which are more expoſed. This every one who hath ever made any Obſervations on the different Taſte, Size, Colour, or Goodneſs of Fruits which grew on different Parts of the ſame Tree, will, upon the firſt reading, condemn as falſe: for let us only obſerve ſuch Fruits as are ſometimes produced between the Wood-branches and the Wall, and are by them deprived of the Advantage of a free open Air, ſo that they cannot imbibe the kindly Dews, or other aerial Particles of Nouriſhment, nor can they ſo freely expire or throw off any of thoſe crude watery Particles, which were conveyed thro' the Branches of the Tree to the Fruit, and we ſhall find that it never arrives to half its Magnitude, and is always tough, watery, and inſipid, eſpecially in *Peaches*. This is much the ſame with his horizontal Shelters; for the Rows of Tiles being placed in every third Courſe of Bricks, will effectually keep off all Dews and Rain from the Fruits, Leaves, and Branches; both of which are by every one allow'd to be abſolutely neceſſary, and ſerviceable in the Buſineſs of Vegetation.

As to his third Article, *(viz.)* That the Fruit will be much earlier ripe, I am very ready to ſubſcribe to it: for let us but obſerve ſuch Trees, or Parts of Trees, as are in a decaying State, and are not capable of affording proper Nouriſhment to the Fruit, and we ſhall always find theſe Fruits will be the firſt ripe; but how good they will be, either as to Size or Flavour, I ſhall ſubmit to every one's Judgment, that knows but the leaſt of this Matter.

In his fourth Article he ſays, That Walls built with theſe Rows of Tiles, will effectually cure that common Miſtake of leading Wood-branches perpendicularly. This I believe to be true: for a Wall built in this Manner, and well planted with Fruit-trees, will, in leſs than ſeven Years, have no Wood-branches left alive, to train either horizontally or perpendicular; as I can poſitively affirm was the Caſe with a Wall built after his Directions, within my own Obſervation.

But let us now examine the true Cauſes of *Blights*, ſo far as we have been enabled to judge from repeated Obſervations and Experiments.

1. *Blights* then are often cauſed by a continued dry Eaſterly Wind, for ſeveral Days together, without the Intervention of Showers, or any Morning Dew, by which the Perſpiration in the tender Bloſſoms is ſtopp'd, ſo that in a ſhort Time their

Colour is changed, and they wither and decay: And if it ſo happens, that there is a long Continuance of the ſame Weather, it equally affects the tender Leaves; for their perſpiring Matter is hereby thicken'd, and render'd glutinous, cloſely adhering to the Surfaces of the Leaves, and becomes a proper Nutriment to thoſe ſmall Inſects, which are always found preying upon the Leaves and tender Branches of Fruit-Trees, whenever this *Blight* happens; but it is not theſe Inſects which are the firſt Cauſe of theſe *Blights*, as hath been imagin'd by ſome; tho' it muſt be allow'd, that whenever theſe Inſects meet with ſuch a proper Food, they multiply exceedingly, and are inſtrumental in promoting the Diſtemper; ſo that many Times when the Seaſon proves favourable to them, and no proper Care hath been taken to prevent their Miſchief, it is ſurprizing to think how whole Walls of Trees have ſuffered by this Infection.

The beſt Remedy for this Diſtemper, that I have yet known ſucceed, is, gently to waſh and ſprinkle over the Trees from Time to Time with common Water, (that is, ſuch as hath not had any Thing ſteep'd in it) and the ſooner this is perform'd, (whenever we apprehend Danger) the better; and if the young and tender Shoots ſeem to be much infected, waſh them with a woollen Cloth, ſo as to clear them, if poſſible, from all this glutinous Matter, that their Reſpiration and Perſpiration may not be obſtructed; and if we place ſome broad flat Pans or Tubs of Water near the Trees, that the Vapours exhaled from it may be received by the Trees, it will keep their tender Parts in a ductile State, and greatly help them; but whenever this Operation of waſhing the Trees is perform'd, it ſhould be early in the Day, that the Moiſture may be exhal'd before the Cold of the Night comes on, eſpecially if the Nights are froſty; nor ſhould it be done when the Sun ſhines very hot upon the Wall, which would be ſubject to ſcorch up the tender Bloſſoms.

Another Cauſe of *Blights* in the Spring is, ſharp hoary Froſts, which are often ſucceeded by hot Sun-ſhine in the Day-time, which is the moſt ſudden and certain Deſtroyer of Fruits that is known; for the Cold of the Night ſtarves the tender Parts of the Bloſſoms, and the Sun riſing hot upon the Walls before the Moiſture is dry'd from the Bloſſoms, (which being in ſmall Globules, doth collect the Rays of the Sun) a ſcalding Heat is thereby acquired, which ſcorches the tender Flowers and other Parts of Plants.

But that *Blights* are frequently no more than an inward Weakneſs or Diſtemper in Trees, will evidently appear, if we conſider, how often it happens that Trees againſt the ſame Wall, expos'd to the ſame Aſpect, and equally enjoying the Advantages of Sun and Air, with every other Circumſtance which might render them equally healthy, yet very often are obſerv'd to differ greatly in their Strength and Vigour; and as often do we obſerve the weak Trees to be continually blighted, when the vigorous ones in the ſame Situation ſhall eſcape very well; which muſt therefore, in a great meaſure, be aſcribed to their healthy Conſtitution: This Weakneſs therefore in Trees, muſt proceed either from a want of a ſufficient Supply of Nouriſhment to maintain it in perfect Vigour, or from ſome ill Qualities in the Soil where it grows, or perhaps from ſome bad Quality in the Stock, or inbred Diſtemper of the Bud or Cyon, which it had imbibed from its Mother Tree, or from Miſmanagement in the Pruning, *&c.* all which are productive of Diſtempers in Trees, and which are with Difficulty cured thereof. Now, if it was occaſion'd by a Weakneſs in the Tree, we ſhould endeavour to trace out the true Cauſe, firſt, whether it has been occaſion'd by ill Management in the Pruning, which is too often the Caſe; for how common is it to to obſerve *Peach*-Trees train'd up to the full Length of their Branches every Year, ſo as to be carried to the Top of the Wall in a few Years after planting, when at the ſame Time the Shoots have been ſo weak, as ſcarcely to have Strength to produce their Flowers! But this being the utmoſt of their Vigour, the Bloſſoms fall off, and many Times the Branches decay, either the greateſt Part of their Length, or quite down to the Place where they were produced; and this, whenever it happens to be the Caſe, is aſcribed to a *Blight*.

Others there are, who ſuffer their Trees to grow juſt as they are naturally diſpoſed during the Summer Seaſon, without ſtopping of Shoots, or diſburdening their Trees of luxuriant Branches, by which means, two, three, or four Shoots ſhall exhauſt the greateſt Part of the Nouriſhment of the Trees all the Summer: which Shoots, at the Winter Pruning, are intirely cut out, ſo that the Strength of the Tree was employed only in nouriſhing uſeleſs Branches, while the Fruit Branches are thereby render'd ſo weak, as not to be able to preſerve themſelves: The Remedies to this Evil ſhall be explain'd in the Article of *Pruning Peach*-Trees, *&c.*

But if the Weakneſs of the Tree proceeds from an inbred Diſtemper, it is the better Way to remove the Tree at firſt, and after renewing your Earth, plant a new one in its Place.

Or if your Soil is a hot burning Gravel or Sand, in which your Peach Trees are planted; you'll generally find this will be conſtantly their Caſe after their Roots have gotten beyond the Earth of your Borders; for which Reaſon it is much more adviſeable to dig them up, and plant *Grapes*, *Figs*, *Apricots*, or any other Sort of Fruit which may do well in ſuch a Soil, than to be annually diſappointed of your Hopes: For by a Variety of Experiments, it hath been found, that *Apricots* do attract and imbibe Moiſture with a much greater Force than *Peaches* and *Nectarines*, and ſo conſequently are more capable to aſſimilate their nutritive Particles from the Earth, than the other can do, which require to be planted in a generous Soil, which can afford them a Sufficiency of Nouriſhment without much Difficulty: And it is in ſuch Places we often ſee Peaches do Wonders, eſpecially if aſſiſted by Art; but as for the *Vine* and *Fig-tree*, they perſpire but very ſlowly, and are very often in an imbibing State (ſo that a great Part of that fine racy Flavour, with which their Fruits abound when planted in a dry Soil, is probably owing to thoſe refined aerial Principles, which are collected when in a State of Reſpiration;) and therefore, as theſe Trees do not delight in drawing much watery Nouriſhment from the Earth, ſo they will much better ſucceed in ſuch a Soil than in one that is more generous; we ſhould therefore always endeavour to ſuit the particular Sorts of Fruits to the Nature of our Soil, and not pretend to have all Sorts of Fruit good in the ſame Soil.

But there is another Sort of *Blight*, againſt which it is very difficult to guard our Fruit-trees; this is ſharp pinching froſty Mornings, which often happen at the Time when the Trees are in flower, or while the Fruit is very young, and occaſions the Bloſſoms or Fruit to drop off, and ſometimes the tender Parts of the Shoots and Leaves are greatly injur'd thereby.

The only Method yet found out to prevent this Miſchief is, by carefully covering the Walls, either with Mats, Canvas, *&c.* which being faſtened ſo as not to be diſturb'd with the Wind, and ſuffered to remain on during the Night, by taking them off every Day, if the Weather permits, is the beſt and ſureſt Method that hath yet been uſed in this Caſe; which altho' it has been ſlighted and thought of little Service by ſome, yet the Reaſon of their being not ſo ſerviceable as has expected, was, becauſe they have not been rightly uſed, by ſuffering the Trees to remain too long covered, by which Means the younger Branches and Leaves have been rendred too weak to endure the open Air when they are expos'd to it, which has often proved of worſe Conſequence to Trees than if they had remain'd intirely uncovered.

Whereas, when the Covering before mentioned has been performed as it ought to be, it has proved very ſerviceable to Fruits; and many times, when there has been almoſt a general Deſtruction of Fruits in the neighbouring Gardens, there has been a Plenty of them in ſuch Places where they have been covered: And tho' the Trouble may ſeem to ſome to be very great, yet if theſe Coverings are fix'd near the Upper-part of the Wall, and are faſtened to Pullies, ſo as to be drawn up or let down, it will be ſoon and eaſily done, and the Succeſs will ſufficiently repay the Trouble.

But there is another Sort of *Blight* that ſometimes happens later in the Spring, *viz.* in *April* or *May*, which is often very deſtructive to Orchards and open Plantations, and againſt which we know of no Remedy. This is what is call'd a *Fire Blaſt*, which in a few Hours hath not only deſtroy'd the Fruit and Leaves, but many times Parts of Trees, and ſometimes whole ones have been kill'd by it.

This is ſuppoſed to be effected by Volumes of tranſparent flying Vapours, which among the many Forms they revolve into, may ſometimes approach ſo near to a *Hemiſphere*, or Hemicylinder, either in their upper or lower Surfaces, as thereby to make the Beams of the Sun converge enough to ſcorch the Plants or Trees they fall upon, in Proportion to the greater or leſs Convergency of the Sun's Rays.

The learned *Boerhaave*, in his Theory of *Chymiſtry*, obſerves, "That thoſe white Clouds which appear in Summer-time, are, as it were, ſo many Mirrors, and occaſion exceſſive Heat; theſe cloudy Mirrors are ſometimes Round, ſometimes Concave, Polygonous, *&c.* When the Face of the Heavens is covered with ſuch white Clouds, the Sun ſhining among them muſt of Neceſſity produce a vehement Heat, ſince many of his Rays, which would otherwiſe, perhaps, never touch our Earth, are hereby reflected to us: Thus, if the Sun be one Side, and the Clouds on the oppoſite one, they will be perfect Burning Glaſſes: And hence the Phænomena of Thunder.

"I have ſometimes, *continues he*, obſerv'd a kind of hollow Clouds, full of Hail and Snow, during the Continuance of which the Heat was extreme, ſince by ſuch Condenſation they were enabled to reflect much more ſtrongly: After this came a ſharp Cold, and then the Clouds diſcharg'd their

“Hail in great Quantity, to which ſucceeded a moderate
“Warmth. Frozen Concave Clouds therefore, by their
“great Reflections, produce a vigorous Heat, and the ſame,
“when reſolv'd, exceſſive Cold.”

Whence (as Dr. *Hales* obſerves) we ſee, that Blaſts may be occaſion'd by the Reflections of the Clouds, as well as by the above-mentioned Refraction of denſe tranſparent Vapours.

Againſt this Enemy to Fruits, *&c.* as hath been ſaid, there is no Guard to our Plantations, nor any Remedy to cure it: But as this more frequently happens in cloſe Plantations, where the ſtagnating Vapours from the Earth, and the plentiful Perſpirations from the Trees, are pent in for want of a free Air to diſſipate and diſpel them, which are often obſerv'd in ſtill Weather to aſcend in ſo plentiful a manner as to be ſeen by the naked Eye, but eſpecially with reflecting Teleſcopes, ſo as to make a clear and diſtinct object become dim and tremulous, than in thoſe that are planted at a greater Diſtance, or are not ſurrounded with Hills or Woods; this directs us, in the firſt planting of Orchards, *&c.* that we ſhould allow a greater Diſtance between the Trees, and to make choice of clear, healthy Situations, that the Air may freely paſs between the Trees to diſſipate thoſe Vapours before they are formed into ſuch Volumes, whereby the circumambient Air will be clear, and leſs ſubject to ſuch Injuries, as alſo the Fruits which are produced in this clearer Air, will be much better taſted than thoſe that are ſurrounded with a thick rancid Air; for as Fruits are often in a reſpiring State, ſo they conſequently, by imbibing a part of theſe Vapours, are rendred crude and ill-taſted; which is often the Caſe with a great part of our Fruits in *England*.

BLOODWORT; *vide* Lapathum.

BOCCONIA.

This Plant was ſo called after the Reverend *Paul Boccone* of *Sicily*, who has publiſhed ſome curious Books of Botany.

The *Characters* are;

It hath a Flower conſiſting of one Leaf; from the Middle ariſes the Pointal, which afterward becomes an oval-ſhaped pointed Fruit, which is full of Juice, each containing one round Seed.

We have but one *Species* of this Plant, *viz.*

BOCCONIA *racemoſa, ſphondylii folio tomentoſo. Plum. Nov. Gen.* Branching Bocconia, with a woolly Cow Parſnip Leaf.

This Plant is called by Sir *Hans Sloane* in his Natural Hiſtory of *Jamaica*, *Chelidonium majus arboreum, foliis quercinis*; or greater Tree Celandine with Oak Leaves.

It is very common in *Jamaica*, and ſeveral other Parts of *America*; where it grows to the Height of ten or twelve Feet, having a ſtrait Trunk, as large as a Man's Arm, which is covered with a white ſmooth Bark. At the Top it divides into ſeveral Branches, on which the Leaves are placed alternately. Theſe Leaves are eight or nine Inches long, and five or ſix broad, are deeply ſinuated ſometimes almoſt to the Mid-rib, and are of a fine glaucous Colour; ſo that this Plant makes a beautiful Variety among other exotick Plants in the Stove. The whole Plant abounds with a yellow Juice like the greater Celandine, and is of an acrid Nature, ſo that it is uſed by the Inhabitants of *America*, to take off Warts, and Spots from the Eyes.

It is propagated by Seeds, which ſhould be ſown in a Pot filled with light freſh Earth, early in the Spring, and plunged into a Hot-bed of Tanners-bark, obſerving to water it frequently, otherwiſe the Seeds will not grow; when the Plants are come up, they ſhould be each tranſplanted into a ſeparate ſmall Pot, filled with light ſandy Earth, and plunged into the Hot-bed again, obſerving to ſhade the Glaſſes in the Heat of the Day, until the Plants have taken Root; you muſt alſo refreſh them gently with Water, but it ſhould be done frequently, and given to them ſparingly while they are young; for their Stems being very tender, and full of Juice, will rot, if they receive too much Moiſture; but after their Stems are become woody, they will require a plentiful Share of Water, eſpecially in hot Weather, when alſo they ſhould have a large Share of Air, by raiſing the Glaſſes of the Hot bed. The Plants, in two Months after tranſplanting, will have filled theſe ſmall Pots with their Roots; therefore they ſhould be ſhaken out of them, and planted into larger Pots filled will light freſh Earth, and ſhould be plunged into the Bark-ſtove, where they ſhould have a large Share of freſh Air in warm Weather, and muſt be plentifully watered. With this Management I have raiſed theſe Plants upward of two Feet high in one Seaſon, which were alſo very ſtrong in their Stems. Theſe Plants muſt be conſtantly kept in Stoves, allowing them a temperate Heat in Winter; and in Summer they ſhould have a large Share of Air in warm Weather, as alſo a large Share of Moiſture. I have not heard that this Plant has flowered yet in *Europe*, though I doubt not, but in two or three Years, there are ſome Plants in the Phyſick-Garden at *Chelſea* which will flower; but if it were not to flower, the ſingular Beauty of the Plant renders it worthy of a Place in every curious Collection of Plants; and it ſeems the *Indians* were very fond of it, for *Hernandez* tells us, the *Indian Kings* did plant it in their Gardens.

BONDUC; The Nickar-tree, *vulgo*.

The *Characters* are;

It hath a polypetalous or a monopetalous Flower, cut very deeply into ſeveral Segments, but is almoſt of an anomalous Figure: from whoſe Calyx ariſes the Pointal, which afterward becomes a Pod beſet all over with Prickles, in which are contained one or two round hard Seeds.

The *Species* are;

1. BONDUC *vulgare majus polyphyllum. Plum. Nov. Gen.* The yellow Nickar, or Horſe-nickar, *vulgo*.
2. BONDUC *vulgare minus polyphyllum. Plum. Nov. Gen.* The grey or Aſh-coloured Nickar.

Theſe two Plants are very common in *Jamaica*, *Barbados*, and the *Carribbe Iſlands*, where the Children uſe the Fruit for Marbles, their outer Coats being ſo hard, as with great Difficulty to be broken. Theſe Fruit are often brought to *England*, and formerly were uſed for Buttons, but at preſent I don't know any Uſe there is made of them. They commonly grow to the Height of ten or twelve Feet, and twiſt themſelves round any other Trees which grow near them; there is very little Difference between theſe two Plants, except in the Colour of their Fruit, and that the ſecond Sort has ſmaller and rounder Leaves than the firſt.

The Plants are both propagated by Seeds, which are ſo hard as not eaſily to be made to vegetate in *England*. The only way by which I have been able to get theſe Plants from Seeds, is, to put the Seeds into a warm Bed of Tanners-bark, under a Pot, where the Heat of the Tan, and the Moiſture which gets thro' the Pot, will cauſe the Shell of the Fruit to burſt, and the young Plant ſoon after appears; then they may be taken out of the Tan, and put each into a ſmall Pot filled with freſh Earth, and plunged into the Tan again. Theſe Plants will make conſiderable Progreſs, if they are kept in a warm Bed, and frequently watered. They muſt alſo be kept in a Bark-ſtove in Winter, otherwiſe it will be difficult to preſerve them in this Country. Their Stems, Branches and Leaves, are all beſet with ſharp crooked Spines, which faſten themſelves to the Cloaths of any Perſon who approaches them. Theſe Plants are preſerved for Variety by ſuch as are curious in exotick Plants.

BONTIA; *Barbados* Wild Olive, *vulgo*.

The *Characters* are;

It hath a perſonated Flower conſiſting of one Leaf, whoſe upper Lip is erect, the under Lip is divided into three Parts: from out of the Cup ariſes the Pointal, fixed like a Nail in the hinder Part of the Flower; which afterward becomes an oval Fruit, which is ſoft and full of Juice, in which is contained one oblong Shell, incloſing a Nut of the ſame Form.

We know but one *Species* of this Plant at preſent; which is,

BONTIA *laureolæ facie. Hort. Elth.* The *Barbados* Wild Olive.

This Plant is greatly cultivated in the Gardens at *Barbados* for making of Hedges; than which there is not a more proper Plant which will thrive in thoſe hot Countries, it being an Ever-green, and of quick Growth. I have been informed, that from Cuttings (planted in the rainy Seaſon, when they have immediately taken Root) there has been a compleat Hedge four or five Feet high in eighteen Months. And as this Plant will bear cutting very well, ſo it is formed into a very cloſe thick Hedge, which makes a beautiful Appearance. In *England* it is preſerved in Stoves, with ſeveral curious Plants of the ſame Country. It may be raiſed from Seeds, which ſhould be ſown on a Hot-bed early in the Spring (that the Plants may acquire Strength before Winter.) When the Plants are come up, they muſt be tranſplanted out each into a ſeparate Halfpenny Pot, filled with light freſh Earth, and plunged into a moderate Hot-bed of Tanners-bark, obſerving to water and ſhade them until they have taken Root; after which, they muſt have a large Share of Air in warm Weather, and be often refreſhed with Water. In Winter they muſt be placed in the Stove, where they ſhould have a moderate Degree of Warmth, and will often require Water; but it muſt not be given to them in too great Quantities, leſt it rot their tender Roots. In Summer they muſt have a great Share of Air, but will not do well if expoſed abroad: So that they ſhould always remain in the Stove, among Plants which require a great Share of Air, which may be admitted by opening the Glaſſes in very hot Weather. With this Management, theſe Plants will produce Flowers and Fruit in two or three Years from Seed. They may alſo be propagated by Cuttings, which ſhould be planted in the Spring, before the Plants have begun to ſhoot: Theſe muſt be put into Pots filled with light rich Earth, and plunged into a moderate Hot-bed, obſerving to water and ſhade them until they have taken Root; after which they muſt be treated as hath been directed for the ſeedling Plants. Theſe Plants being ever-green, and growing in a pyramidal Form, make a pretty Variety in the Stove, amongſt other exotick Plants.

BONUS HENRICUS; *vide* Chenopodium.

BORDERS: The Uſe of theſe in a Garden is to bound and incloſe *Parterres*, to prevent them being injur'd by walking in them: Theſe are commonly render'd very ornamental by means of the Flowers, Shrubs, *&c.* that are planted in them.

Theſe ought to be laid with a Riſing in the Middle, becauſe if they are flat, they are not agreeable to the Eye.

As for their Breadth, five or ſix Feet are often allow'd for the largeſt, and four for the leſſer.

Borders are of four Sorts; thoſe are the moſt common that are continu'd about *Parterres* without any Interruption, and are wrought with a ſharp Riſing in the Middle like an Aſs's Back, and planted with low Shrubs and Flowers.

The ſecond Sort of *Borders* are ſuch as are cut into Compartments at convenient Diſtances by ſmall Paſſages; and being alſo rais'd in the Middle, as before-mentioned, are likewiſe ſet off with Shrubs.

The third Sort are ſuch as are laid even and flat, without Flowers, having only a Verge of Graſs in the Middle, being edg'd with two ſmall Paths rak'd ſmooth and ſanded: Theſe are ſometimes garniſh'd with flowering Shrubs and Flowers of large Growth, or with Vaſes and Flower-pots plac'd regularly along the Middle of the Verge of Graſs.

The fourth Sort are quite plain, and are only ſanded, as in the *Parterres* of *Orangery*, and are filled with Caſes rang'd in a regular Order along thoſe *Borders* which are edg'd with *Box* on the Sides next to the Walks, and on the other, with Verges and Graſs-work next the *Parterre*: Sometimes a Yew is planted between each Caſe, which makes the *Border* appear richer, and the *Parterres* handſomer during the Winter Seaſon.

Borders are made either ſtrait, circular, or in Cants, and are turn'd into Knots, Scrolls, Volutes, and other Compartments.

Floriſts do alſo make *Borders* either along Walks or detach'd, and in theſe they raiſe their fineſt and choiceſt Flowers: Theſe are frequently encompaſs'd with Border-boards painted Green, which makes them look exceeding neat.

But in large *Parterres* this is not to be expected; which if they be ſtock'd with Flowers, ſucceeding one another in their ſeveral Seaſons, it is ſufficient, ſo that nothing appears bare and naked.

It is uſual to diſcontinue the *Borders* at the Ends next to the Houſe, that the Embroidery and Riſe of the *Parterre* may not be hidden by the Shrubs and flowering Plants, and that the Deſign may be better judged of.

And ſometimes there are branch'd out of it Foliage, Palm-leaves and Shells ſporting among the Sands.

BORRAGO; [or *Borago*, which ſignifies much the ſame as *Courage*, becauſe it is ſo good a Raiſer of the Spirits.] Borrage.

The *Characters* are;

The Leaves are broad and rough; the Flowers conſiſt of one Leaf, are of a Wheel-ſhape, and divided into five Segments almoſt to the Bottom, which end in ſharp Points like a Star; the Apices in the Middle of the Flower are ſharp-pointed, and adhere together; the Seeds are rough, and appear like a Viper's Head.

The *Species* are;

1. Borrago *floribus cæruleis. J. B.* The common *Borrage*, with blue Flowers.

2. Borrago *flore palleſcente, roſeo aut ſuave-rubente. Tourn.* The common *Borrage*, with a pale Roſe-colour'd Flower.

3. Borrago *floribus albis. J. B.* The common *Borrage*, with a white Flower.

The firſt Sort is very common in all Parts of *England*, being often found upon Dunghils, and in publick Roads, where the Seeds have been ſcattered from Gardens, but is hardly a Native Plant of our Iſland; however, it is ſo far naturalized amongſt us, that where-ever it is ſuffered to ſtand till its Seeds are dropt upon the Ground, there will always be a plentiful Crop.

The Seeds of this Plant may be ſown in the Spring; it will grow in almoſt any Soil, but beſt in that which is dry. This Plant is often uſed in the Kitchen, and for cool Tankards in Summer-time, and the Flowers are uſed in medicinal Cordials.

The White and Roſe-coloured Flowers are accidental Varieties of the common Sort; but the Seeds of either Sort being ſown ſeparately, will produce ſome Plants of the ſame kind.

BOSQUETS, are Groves; ſo call'd from *Boſchetto*, *Italian*, which is a Diminutive of *Boſco*, a Wood or Grove.

Theſe are ſmall Compartments of Gardens, which are form'd of Trees, Shrubs, or tall large growing Plants, planted in Quarters, and are either diſpos'd regularly in Rows, or in a more wild or accidental manner, according to the Fancy of the Owner: Theſe Quarters are commonly ſurrounded with ever-green Hedges, and the Entrances form'd into regular Portico's with Yews, which are by far the beſt, and moſt tonſile Trees for this Purpoſe. In the Inſide of theſe Quarters may be made ſome Walks, either ſtrait or winding; which, if the Quarters are large, ſhould be ſix or eight Feet broad, and may be laid with Turf, and kept well mow'd and roll'd, which will render the walking much eaſier and pleaſanter than if the Walks are only the common Earth, which in ſmaller Quarters can't be otherwiſe; for if the Trees are cloſe, and the Walks narrow, ſo as to be ſhaded and over-hung by the Trees, the Graſs will not grow.

Theſe Quarters may be alſo ſurrounded with Hedges of *Lime*, *Elm*, *Hornbeam*, or *Beech*; which ſhould be kept well ſhear'd, and not ſuffered to riſe too high; that the Heads of the Trees may be fully ſeen over them, and the Stems only hid from the Sight, when in the Walks on the Outſide of the Quarters.

In the planting of theſe *Boſquets*, you ſhould obſerve to mix the Trees, which produce their Leaves of different Shapes, and various Shades of Green, and hoary or mealy Leaves, ſo as to afford an agreeable Proſpect; beſides, there is a great Variety of different Fruits which theſe Trees produce in Autumn, which altho' of little or no Uſe, that we know of, yet have a very good Effect, in affording an agreeable Variety for ſome Time after the Leaves are gone; as the *Euonymus* or *Spindle-Tree*, the *Opulus* or *Marſh-Elder*, the *Cock-ſpur Hawthorn*, with many other Sorts, too many to mention in this Place: But I would adviſe never to mix Ever-greens with deciduous Trees; for beſides the ill Effect it hath to the Sight, (eſpecially in Winter) they ſeldom thrive well together; ſo that thoſe Quarters where you intend to have Ever-greens, ſhould be wholly planted therewith; and in the other Parts, mix as many Varieties of different Trees which caſt their Leaves, as you can conveniently; and alſo plant ſome of the largeſt growing Flowers, (eſpecially near the Outſide of the Quarters) which will add greatly to the Variety, if they have but Air enough to grow.

Theſe *Boſquets* are proper only for ſpacious Gardens, being expenſive in their firſt making, as alſo in keeping.

BOTRYS; *vide* Chenopodium.

BOX TREE; *vide* Buxus.

BRANCA URSINA; *vide* Acanthus.

BRASICA. The Cabbage.

The *Characters* are;

The Leaves are large, fleſhy, and of a glaucous Colour; the Flowers conſiſt of four Leaves, which are ſucceeded by long Taper Pods, containing ſeveral round acrid Seeds.

The *Species* are;

1. Brasica *Capitata alba. C. B.* The common white *Cabbage*.

2. BRASICA *Capitata rubra.* *C. B.* The red *Cabbage.*

3. BRASICA *Capitata alba minor Muſcovitica.* *H. A.* The *Ruſſian Cabbage.*

4. BRASICA *Capitata alba compreſſa.* *Boerh. Ind.* The flat-ſided *Cabbage.*

5. BRASICA *Capitata alba pyramidalis.* The Sugar-loaf *Cabbage.*

6. BRASICA *Capitata alba præcox.* The early *Batterſea Cabbage.*

7. BRASICA *Sabauda Hyberna.* *Lob. Ic.* The white *Savoy Cabbage.*

8. BRASICA *Capitata viridis Sabauda.* *Boerh. Ind.* The green *Savoy Cabbage.*

9. BRASICA *fimbriata.* *C. B.* The *Boor Cole.*

10. BRASICA *capitata vireſcens Italica criſpa.* *Munt. Hiſt.* The green *Broccoli.*

11. BRASICA *Italica Broccoli dicta.* The *Italian Broccoli.*

12. BRASICA *radice Nappiformi.* *Tourn.* The Turnip-rooted *Cabbage.*

13. BRASICA *Cauliflora.* *C. B.* The *Cauliflower.*

14. BRASICA *gongylodes.* *C. B. P.* The Turnep Cabbage.

15. BRASICA *aſparagodes criſpa.* *C. B. P.* Curled Colewort.

16. BRASICA *peregrina moſchum olens.* *H. R. Par.* The Muſk Cabbage.

17. BRASICA *maritima arborea, ſeu procerior ramoſa.* *Mor. Hiſt.* Branching Tree Cabbage from the Sea-coaſt.

18. BRASICA *rugoſa, longioribus foliis.* *J. B.* Brown Broccoli.

19. BRASICA *arvenſis.* *C. B. P.* Common Colewort.

20. BRASICA *Alpina perennis.* *Tourn.* Perennia *Alpine* Colewort.

21. BRASICA *campeſtris perfoliata, flore albo.* *C. B. P.* Perfoliated wild Cabbage, with a white Flower.

22. BRASICA *campeſtris perfoliata, flore purpureo.* *C. B. P.* Perfoliated wild Cabbage, with a purple Flower.

The common white, red, flat, and long-ſided *Cabbages* are chiefly cultivated for Winter Uſe: The Seeds of theſe Sorts muſt be ſown in the middle of *March*, in Beds of good freſh Earth, and in *April*, when the young Plants will have about eight Leaves; they ſhould be prick'd out into ſhady Borders, about three Inches ſquare; that they may acquire Strength, and to prevent their growing long-ſhank'd.

About the Middle of *May*, you muſt tranſplant them out, where they are to remain for good, (which in the Kitchen-Gardens near *London*, is commonly between *Cauliflowers*, *Artichokes*, &c. at about two Feet Diſtance in the Rows); but if they are planted, for a full Crop in a clear Spot of Ground, the Diſtance from Row to Row ſhould be three Feet, and in the Rows two Feet four Inches aſunder: If the Seaſon ſhould prove dry when they are tranſplanted out, you muſt water them every other Evening until they have taken freſh Root; and afterwards, as the Plants advance in Height, you ſhould draw the Earth about their Stems with a Hough, which will keep the Earth moiſt about their Roots, and greatly ſtrengthen the Plants: You muſt alſo obſerve to keep them clear from Weeds, which are apt to draw the Plants up tall, (if ſuffer'd to grow amongſt them) and often ſpoil them.

Theſe *Cabbages* will ſome of them be fit for Uſe ſoon after *Michaelmas*, and will continue until *February*, if they are not deſtroyed by bad Weather: To prevent which, the Gardeners near *London*, pull up their *Cabbages* in *November*, and trench their Ground up in Ridges, laying their *Cabbages* againſt their Ridges as cloſe as poſſible on one Side, burying their Stems in the Ground: In this manner they let them remain till after *Chriſtmas*, when they cut them for the Market; and altho' the outer Part of the *Cabbage* be decay'd, (as is often the Caſe in very wet or hard Winters) yet, if the *Cabbages* were large and hard when laid, the Inſide will remain ſound.

The *Ruſſian Cabbage* was formerly in much greater Eſteem than at preſent, it being now only to be found in particular Gentlemens Gardens, who cultivate it for their own Uſe, and is rarely ever brought to the Market. This muſt be ſown in the Spring of the Year, and managed as thoſe before directed, with this Difference only, that theſe muſt be ſooner planted out for good, and muſt have an open clear Spot of Ground, and require much leſs Diſtance every Way, for it is but a very ſmall hard *Cabbage*. Theſe will be fit for Uſe in *July* or *Auguſt*, but will not continue long before they will break and run up to Seed. The beſt Method to have theſe *Cabbages* good, is to procure freſh Seeds from abroad every Year; for 'tis apt to degenerate in *England* in a few Years.

The early *Batterſea* and Sugar-loaf *Cabbages* are commonly ſown for Summer Uſe, and are what the Gardeners about *London* commonly call *Michaelmas Cabbages*. The Seaſon for ſowing of theſe is about the End of *July*, in an open Spot of Ground; and when the Plants have got eight Leaves, you muſt prick them out into Beds at about three Inches Diſtance every Way, that the Plants may grow ſtrong and ſhort-ſhank'd; and in the Beginning of *October* you ſhould plant them out for good: The Diſtance that theſe require is, three Feet Row from Row, and two Feet aſunder in the Rows. The Gardeners near *London* commonly plant theſe *Cabbages* upon the ſame Spot of Ground where their Winter *Spinage* is ſown; ſo that when the *Spinage* is clear'd off in the Spring, the Ground will have a Crop of *Cabbages* upon it; you muſt therefore clear off the *Spinage* juſt round each Plant early in the Spring, that with a Hough you may draw the Earth up to the Stem; and when all your *Spinage* is clear'd off, which is commonly in *April*, you muſt hough down all the Weeds, and draw up the Earth again about your *Cabbage* Plants.

In *May*, if your Plants were of the early Kind, they will turn in their Leaves for Cabbaging; at which Time, the Gardeners near *London*, in order to obtain them a little ſooner, tie in their Leaves cloſe with a ſlender Oſier Twig to blanch their Middle; by which means they have them, at leaſt, a Fortnight ſooner than they could have if they were left untied.

The early *Batterſea Cabbage* being the firſt we ſhould chuſe, (if for a Gentleman's Uſe) to plant the fewer of them, and a greater Quantity of the Sugar-loaf Kind, which comes after them; for the *Batterſea* Kind will not ſupply you long, they generally cabbaging apace when they begin, and as ſoon grow hard and burſt open: But the Sugar-loaf Kind is longer before it comes, and is as ſlow in its cabbaging, and, being of a hollow Kind, will continue good for a long Time: I have known a large Quarter of Ground which was planted with this Sort of *Cabbage* for Market Uſe, which hath afforded a Supply for near three Months together. This, tho' of ſingular Service to a Gentleman's Garden, is not ſo much for the Advantage of the Market Gardener, who loves to have his Ground clear'd ſooner, that he may have another Crop upon it, of *Celery*, *Endive*, &c. which is more to his Purpoſe; for they paying large Rents for their Land, are oblig'd to have as many Crops in a Year from it as poſſible.

Altho' I before have adviſ'd the planting out of your *Cabbages* for good in *October*; yet the Sugar-loaf Kind may be planted out in *February*, and will ſucceed as well as if planted earlier, with this Difference only, that they will be later before they cabbage. You ſhould alſo reſerve ſome Plants of the *Batterſea* Kind in ſome well-ſhelter'd Spot of Ground, to ſupply your Plantation, in caſe of a Defect.

The *Savoy Cabbages* are propagated for Winter Uſe, as being generally eſteem'd the better when pinch'd by the Froſt; theſe muſt be ſown about the Beginning of *April*, and treated after the manner as was directed for the common *white Cabbage*, with this Difference, that theſe may be planted at a cloſer Diſtance than thoſe; two Feet ſquare will be ſufficient: Theſe are always much the better when planted in an open Situation, which is clear from Trees and Hedges; for in cloſe Places they are very ſubject to be eaten almoſt up by Caterpillars and other Vermin, eſpecially if the *Autumn* prove dry.

The *Boor-Cole* may be alſo treated in the ſame manner, but need not be planted above one Foot ſquare: Theſe are never eaten 'till the Froſt hath render'd them tender; for otherwiſe they are tough and bitter.

The Seeds of the *Broccoli* (of which there are ſeveral Kinds, *viz.* the *Roman*, *Neapolitan*, and *black Broccoli*, with ſome others, but the *Roman* is chiefly preferr'd to them all) ſhould be ſown about the Middle or Latter End of *May*, in a moiſt Soil; and when the Plants are grown to have eight Leaves, tranſplant them into Beds, (as was directed for the common *Cabbage*) and toward the Middle or Latter End of *July* they will be fit to plant out for good, which ſhould be into ſome well-ſhelter'd Spot of Ground, but not under the Drip of Trees: The Diſtance theſe require is about a Foot and half every Way. The Soil in which they ſhould be planted ought to be rather light than heavy, ſuch as are the Kitchen Gardens near *London*: If your Plants ſucceed well (as there will be little Reaſon to doubt, unleſs the Winter prove extreme hard) they will begin to ſhew their ſmall Heads, which are ſomewhat like a *Cauliflower*, about the Beginning of *December*, and will continue eatable 'till the End of *March*.

The Manner of preparing them for the Table, is this; When your Heads are grown to their full Bigneſs, (as may be eaſily known by their dividing, and beginning to run up) then you ſhould cut them off, with about four Inches of the tender Stem to them; then ſtrip off the outer Skin of the Stem, and after having waſh'd them, boil them in a clean Linen-cloth, (as is practis'd for *Cauliflowers*) and ſerve them up with Butter, *&c.* and if they are of a right Kind, they will be tenderer than any *Cauliflowers*, tho' very like unto them in Taſte. When your firſt Heads are cut off, in about a Month's Time after they will produce a Number of Side-ſhoots, which being cut and ſtripp'd of their outer Skin, are very tender and good, almoſt equalling *Aſparagus*. The ſureſt Way to have theſe good, is to be furniſh'd with freſh Seeds from *Italy* every Year; for they are very apt to degenerate in a Year or two, if the Seeds are ſaved in *England*.

The Manner of ſaving the Seeds of all theſe Sorts of *Cabbages*, is, about the Middle of *October*, you ſhould make choice of ſome of your beſt *Cabbages*, which you ſhould pull up, and carry to ſome Shed, or other cover'd Place, where you ſhould hang them up for three or four Days by their Stalks, that the Water may drain from between their Leaves; then plant them in ſome Border under a Hedge or Pale, quite down to the Middle of the *Cabbage*, leaving only the Upper-part of the *Cabbage* above-ground, obſerving to raiſe the Earth up about it, ſo that it may ſtand a little above the Level of the Ground; eſpecially if the Ground is wet, they will require to be rais'd pretty much.

If the Winter ſhould prove very hard, you muſt lay a little Straw or Peaſe Haulm lightly upon them; taking it off as often as the Weather proves mild, leſt by keeping them too cloſe they ſhould rot. In the Spring of the Year theſe *Cabbages* will ſhoot out ſtrongly, and divide into a great number of ſmall Branches; you muſt therefore ſupport their Stems, to prevent their being broke off by the Wind; and if the Weather ſhould be very hot and dry, you ſhould refreſh them with Water once a Week, which will greatly promote their Seeding, eſpecially at the Time when they are in Flower.

When the Pods begin to change brown, you will do well to cut off the extreme Part of every Shoot; which will ſtrengthen your Seeds: And it is generally obſerv'd, that thoſe Seeds which grow near the Top of the Shoots, are very ſubject to run to Seed before they cabbage; ſo that by this there will be no Loſs, but a great Advantage, eſpecially if you have more regard to the Quality than to the Quantity of the Seeds; which indeed is not always the Caſe, when it is intended for Sale: but thoſe who ſave it for their own Uſe, ſhould be very careful to have it good.

When your Seeds begin to ripen, you muſt be particularly careful that the Birds do not deſtroy it; for they are very fond of theſe Seeds. In order to prevent their Miſchief, ſome uſe old Nets, which they throw over their Seeds, to prevent their getting to it: But this will not always do; for unleſs the Nets are very ſtrong, they will force their Way through them, as I have often ſeen: but the beſt Method I know, is to get a Quantity of Birdlime, and dawb over a parcel of ſlender Twigs, which ſhould be faſten'd at each End to ſtronger Sticks, and placed near the upper Part of the Seed, in different Places, ſo that the Birds may alight upon them, by which means they will be faſtened thereto; where you muſt let them remain for a conſiderable Time, if they cannot get off themſelves: And altho' there ſhould not above two or three Birds be caught, yet it will ſufficiently terrify the reſt, that they will not come to that Place again for a conſiderable Time, (as I have experienced.)

When your Seeds are fully ripe, you muſt cut it off; and after drying it, threſh it out and preſerve it in Bags for Uſe.

But in planting of *Cabbages* for Seed, I would adviſe never to plant more than one Sort in a Place, or near one another. As for Example: Never plant *red* and *white Cabbages* near each other, nor *Savoy* with either *white* or *red Cabbages*: For I am very certain they will, by the Commixture of their *Effluvia*, produce a Mixture of Kinds: And it is wholly owing to this Neglect, that the Gardeners rarely ſave any good *red Cabbage-ſeed* in *England*, but are obliged to procure freſh Seeds from abroad, as ſuppoſing the Soil or Climate of *England* alters them from Red to White, and of a mix'd Kind between both; whereas, if they would plant *red Cabbages* by themſelves for Seeds, and not ſuffer any other to be near them, they might continue the Kind as good in *England*, as in any other Part of the World.

Cauliflowers have of late Years been ſo far improv'd in *England*, as to exceed in Goodneſs and Magnitude what are produced in moſt Parts of *Europe*, and by the Skill of the Gardener are continued for ſeveral Months together; but the moſt common Seaſon for them is in *May*, *June*, and *July*. I ſhall therefore begin with Directions for obtaining them in this Seaſon.

Having procured a parcel of good Seed, of an early Kind, you muſt ſow it on the Tenth of *Auguſt*, upon an old Cucumber-bed or Melon-bed, ſifting a little Earth over the Seeds about a Quarter of an Inch thick; and if the Weather ſhould prove extreme hot and dry, you ſhould ſhade the Beds with Mats, to prevent the Earth from drying too faſt, which would endanger the ſpoiling of your Seed; and give it gentle Waterings, as you may ſee occaſion; in about a Week's Time your Seed will appear above-ground, when you muſt take off your Coverings by degrees. But do not expoſe your Plants too much to the open Sun at firſt: In about a Month's Time after ſowing, your Plants will be fit to prick out; you ſhould therefore put ſome freſh Earth upon your old Cucumber or Melon-beds, into which you ſhould prick your young Plants, at about two Inches ſquare, obſerving to ſhade and water them at firſt planting; but do not water them too much after they are growing, nor ſuffer them to receive too much Rain, if the Seaſon ſhould prove wet, which would be apt to make them black-ſhank'd, (as the Gardeners term it, which is no leſs than a Rottenneſs in their Stems) and is the Deſtruction of the Plants ſo affected.

In this Place they ſhould continue 'till about the ſixteenth Day of *October*, when they muſt be removed into the Place where they are to remain during the Winter Seaſon, which, for this firſt ſowing, is commonly under Bell or Hand-glaſſes, to have early *Cauliflowers*; and theſe ſhould be of an early Kind: But in order to have a Succeſſion during the Seaſon, we ſhould be provided with another more late Kind, which ſhould be ſown four or five Days after the other, and manag'd as was directed for them.

In order to have very early *Cauliflowers* we ſhould make choice of a good rich Spot of Ground, that is well defended from the *North*, *Eaſt*, and *Weſt* Winds with Hedges, Pales, or Walls: This Ground ſhould be well trench'd, burying therein a good Quantity of rotten Dung; then level your Ground: And if it be naturally a wet Soil, you ſhould raiſe it up in Beds about two Feet and a half broad, and four Inches above the Level of the Ground. But if your Ground is moderately dry, you need not raiſe it at all: Then plant your Plants about two Feet four Inches Diſtance from Glaſs to Glaſs in the Rows, always putting two good Plants under each Glaſs, which may be at about four Inches from each other; and if you deſign 'em for a full Crop, they may be three Feet, Row from Row: But if you intend to make Ridges for Cucumbers or Melons between the Rows of *Cauliflower-Plants*, (as is generally practis'd by the Gardeners near *London*) you muſt then make your Rows eight Feet aſunder.

When you have planted your Plants, if the Ground is very dry, you ſhould give them a little Water, and then ſet your Glaſſes over them, which may remain cloſe down upon them, until they have taken Root, which will be in about a Week or ten Days time; unleſs there ſhould be a kindly Shower of Rain, in which caſe you may ſet off the Glaſſes, that the Plants may receive the Benefit of it; and in about ten Days after planting, you ſhould be provided with a parcel of forked Sticks, or Bricks, with which you ſhould raiſe your Glaſſes about three or four Inches to the Southward, that your Plants may have free Air: In this manner your Glaſſes ſhould remain over the Plants, Night and Day, unleſs in froſty Weather, when you ſhould ſet them down as cloſe as poſſible; or if the Weather ſhould prove very warm, which many times happens in *November* and ſometimes in *December*, in this Caſe, you ſhould keep your Glaſſes off in the Day-time, and put them on only in the Night, leſt by keeping the Glaſſes over them too much, you ſhould draw them into Flower at that Seaſon; which is many times the Caſe in mild Winters, eſpecially if unſkilfully manag'd.

Towards the latter end of *February*, if the Weather be mild, you ſhould prepare another good Spot of Ground, to remove ſome of the Plants into, from under the Glaſſes, which ſhould be well dung'd and trench'd (as before); then ſet off your Glaſſes; and after making choice of one of the moſt promiſing Plants under each Glaſs which ſhould remain for good, take away the other Plant, by raiſing it up with a Trowel, *&c.* ſo as to preſerve as much Earth to the Roots as poſſible; but have a great Regard to the Plant that is to remain, not to diſturb or prejudice its Roots: Then plant your Plants which you have taken out, at the Diſtance before directed, *viz.* if for a full Crop, three Feet, Row from Row; but if for Ridges of Cucumbers between them, eight Feet, and two Feet four Inches Diſtance in the Rows. Then with a ſmall Hough draw the Earth up to the Stems of the Plants which were left under the Glaſſes, taking great Care not to let the Earth fall into their Hearts: Then ſet your Glaſſes over them again, raiſing your Props an Inch or two higher, to give them more Air, obſerving to take them off whenever there may be ſome gentle Showers, which will greatly refreſh the Plants.

And in a little time after, if you find your Plants grow ſo faſt as to fill the Glaſſes, you ſhould then ſlightly dig about the Plants, and raiſe the Ground about them in a Bed broad enough for the Glaſſes to ſtand, and about four Inches high, which will give your Plants a great deal of Room, when the Glaſſes are ſet over them; and by this Means they may be kept cover'd until *April*, which otherwiſe they could not, without Prejudice to the Leaves of the Plants: And this is a great Advantage to them; for many times we have Returns of ſevere Froſts at the latter End of *March*, which prove very hurtful to theſe Plants, if expos'd thereto, eſpecially after having been nurs'd up under Glaſſes.

After you have finiſh'd your Beds, you may ſet your Glaſſes over your Plants again, obſerving to raiſe your Props pretty high, eſpecially if the Weather be mild, that they may have free Air to ſtrengthen them; and in mild ſoft Weather ſet off your Glaſſes, as alſo in gentle Showers of Rain: And now you muſt begin to harden them by degrees to endure the open Air; however, it is adviſeable to let your Glaſſes remain over them as long as poſſible, if the Nights ſhould be froſty, which will greatly forward your Plants: but be ſure do not let your Glaſſes remain upon them in very hot Sun-ſhine, eſpecially if their Leaves preſs againſt the Sides of the Glaſſes: For I have often obſerv'd, in ſuch Caſes, that the Moiſture which hath riſen from the Ground, together with the Perſpiration of the Plants, which, by the Glaſſes remaining over them, hath been detain'd upon the Leaves of the Plant, and when the Sun hath ſhone hot upon the Sides of the Glaſſes, hath acquir'd ſuch a powerful Heat from the Beams thereof, as to ſcald all their larger Leaves, to the no ſmall Prejudice of the Plants: Nay, ſometimes I have ſeen large Quantities of Plants ſo affected herewith, as never to be worth any thing after.

If your Plants have ſucceeded well, towards the End of *April* ſome of them will begin to Fruit; you muſt therefore look over them carefully every other Day, and when you ſee the Flower plainly appear, you muſt break down ſome of the inner Leaves over it to guard it from the Sun, which would make the Flower yellow and unſightly; and when you find your Flower at its full Bigneſs, (which you may know by its Outſide, parting, as if it would run) you muſt then draw it out of the Ground, and not cut them off, leaving the Stalk in the Ground; as is by ſome practis'd: And if they are deſign'd for preſent Uſe, you may cut them out of their Leaves; but if deſign'd to keep, you ſhould preſerve their Leaves about them, and put them into a cool Place. The beſt Time for pulling of them, is in a Morning, before the Sun hath exhal'd the Moiſture; for *Cauliflowers* pull'd in the Heat of the Day, loſe that Firmneſs which they naturally have, and become tough.

But to return to our *Second Crop* (the Plants being rais'd and manag'd as was directed for the *Early Crop*, until the Middle or latter End of *October*) you muſt then prepare ſome Beds, either to be cover'd with Glaſs-Frames, or arch'd over with Hoops, to be cover'd with Mats, *&c.* Theſe Beds ſhould have ſome Dung laid in the Bottom about ſix Inches or a Foot thick, according to the Size of your Plants; for if they are ſmall, the Bed ſhould be thicker of Dung, to bring them forward, and ſo *vice verſa*; this Dung ſhould be beat down cloſe with a Fork, in order to prevent the Worms from finding their Way through it: Then lay ſome good freſh Earth about four or five Inches thick thereon, in which you ſhould plant your Plants about two Inches and a half ſquare, obſerving to ſhade and water them until they have taken freſh Root: But be ſure do not keep your Coverings cloſe; for the Warmth of the Dung will occaſion a large Damp in the Bed, which, if pent in, will greatly injure the Plants.

When your Plants have taken Root, you muſt give them as much free open Air as poſſible, by keeping the Glaſſes off in the Day-time as much as the Weather will permit; and in the Night, or at ſuch Times as the Glaſſes require to be kept on, raiſe them up with Bricks to let in freſh Air, unleſs in froſty Weather; at which time the Glaſſes ſhould be cover'd with Mats, Straw, or Peaſe-haulm, *&c.* but this is not to be done but in very hard Froſts: You muſt alſo obſerve to guard them againſt great Rains, which in Winter-time are very hurtful to them; and if the under Leaves grow yellow and decay, be ſure to pick them off, for if the Weather ſhould prove very bad in Winter, ſo that you ſhould be oblig'd to keep them cloſe cover'd for two or three Days together, as it ſometimes happens, theſe decay'd Leaves will render the inclos'd Air very noxious, and the Plants inſpiring pretty much at that time, are often deſtroy'd in vaſt Quantities.

In the Beginning of *February*, if the Weather be mild, you muſt begin to harden your Plants by degrees, that they may be prepar'd for Tranſplantation; and the Ground where you intend to plant your *Cauliflowers* out for good, (which ſhould be quite open from Trees, *&c.* and rather moiſt than dry) having been well dung'd and dug, ſhould be ſown with *Radiſhes* a Week or Fortnight before you intend to plant out your *Cauliflowers*: The Reaſon why I mention the ſowing of *Radiſhes* particularly, is this, (*viz.*) that if there are not ſome *Radiſhes* amongſt them, and the Month of *May* ſhould prove hot and dry, as it ſometimes happens, the Fly will ſeize your *Cauliflowers*, and eat them full of Holes, to their Prejudice, and ſometimes their Deſtruction; whereas, if there are *Radiſhes* upon the Spot, the Flies will take to them, and never meddle with the *Cauliflowers* ſo long as they laſt: Indeed the Gardeners near *London* mix *Spinage* with their *Radiſh* Seed, and ſo have a double Crop; which is an Advantage where Ground is dear, or that Perſons are ſtreightened for Room: otherwiſe it is very well to have only one Crop amongſt the *Cauliflowers*, that the Ground may be cleared in time.

Your Ground being ready, and the Seaſon good, about the Middle of *February*, you may begin to plant out your *Cauliflowers*: The Diſtance which is generally allow'd by the Gardeners near *London*, (who plant other Crops between their *Cauliflowers* to ſucceed them, as *Cucumbers* for pickling, and Winter *Cabbages*) is every other Row four Feet and a half apart, and the intermediate Rows two Feet and a half, and two Feet two Inches Diſtance in the Rows; ſo that in the Middle, or towards the latter End of *May*, (when the *Radiſhes* and *Spinage* are cleared off) they put in Seeds of *Cucumbers* for Pickling, in the Middle of the wide Rows, at three Feet and a half apart; and in the narrow Rows, plant *Cabbages* for Winter Uſe, at two Feet two Inches Diſtance, ſo that theſe ſtand each of them exactly in the Middle of the Square between four *Cauliflower*-Plants; and theſe, after the *Cauliflowers* are gone off, will have full Room to grow, and the Crop be hereby continu'd in a Succeſſion through the whole Seaſon.

About three Weeks or a Month after your *Cauliflowers* are planted out, the *Radiſhes* between them will be fit to hough; at which time, when you are houghing out the *Radiſhes*, where they are too thick, you ſhould cut off all ſuch as grow immediately about the *Cauliflowers*, and would prove hurtful to them, by drawing them up tall and weak, and alſo at that time draw the Earth up to the Stems of the Plants, being careful not to let any get into their Hearts, (as was before directed;) and when your *Radiſhes* are fit to pull, be ſure to clear round the *Cauliflowers* firſt, and keep drawing the Earth up to their Stems as they advance in Height, which will keep their Stems from being harden'd by the Weather, and be of ſingular Service to your Plants.

There are many People, who are very fond of watering *Cauliflower* Plants in Summer, but the Gardeners near *London* have almoſt wholly laid aſide this Practice, as finding a deal of Trouble and Charge to little Purpoſe; for if the Ground be ſo very dry as not to produce tolerable good *Cauliflowers* without Water, it ſeldom happens, that watering of them renders them much better; and when once they have been water'd, if it is not conſtantly continu'd, it had been much better for them if they never had had any; as alſo, if it be given them in the Middle of the Day, it rather helps to ſcald them: So that, upon the Whole, if Care be taken to keep the Earth drawn up to their Stems, and clear them from every Thing that grows near them, that they may have free open Air, we ſhall find that they will ſucceed better without than with Water, where any of theſe Cautions are not ſtrictly follow'd.

When your *Cauliflowers* begin to Fruit, you muſt often look over them, to turn down their Leaves, as was before directed, to preſerve their Whiteneſs; and when they are full grown, obſerve the former Directions in pulling them, *&c.* But where-ever you meet with an extraordinary good *Cauliflower*, whoſe Curd is hard and white, and perfectly free from any Frothineſs about the Edges, you ſhould ſuffer it to remain for Seed, keeping the Leaves cloſe down upon it until the Flower hath ſhot out Stems, and then remove the Leaves from them by degrees, but do not expoſe them too much to the open Air at firſt: As the Stems advance, you muſt take the Leaves quite away; and when they begin to branch out, you ſhould fix three pretty ſtrong Stakes, at equal Angles, about it, ſurrounding them with Packthread, *&c.* to ſupport their Branches, which would be otherwiſe liable to break with the Wind.

When your Pods begin firſt to be form'd, if the Weather be dry, you ſhould give them a little Water all over, (with a Watering-pot that hath a Roſe to it) which will promote the Progreſs of the Seeds, and preſerve 'em from the Mildew, which is often hurtful to theſe Seeds; and when your Seeds are ripe, you muſt cut it off, and hang it up to dry, and rub it out, as was directed for *Cabbage* Seed: And although your Flowers do not produce ſo much Seed as thoſe which were of a ſofter or frothy Nature, yet the Goodneſs of ſuch Seeds will ſufficiently recompenſe for the Quantity; and any Perſon who was to purchaſe his Seeds, had better give ten Shillings an Ounce for ſuch Seeds, than two for the Seeds commonly ſav'd for Sale; as the Gardeners about *London* have experienc'd, who will never buy any Seeds of this Kind, that they do not know how they were ſav'd.

But in order to have a third Crop of *Cauliflowers*, you ſhould make a ſlender Hot-bed in *February*, in which you ſhould ſow the Seeds, covering them a quarter of an Inch thick with light Mould, and covering the Bed with Glaſs-frames;

you ſhould now and then gently refreſh the Bed with Water, obſerving to raiſe the Glaſſes with Bricks in the Day-time to let in freſh Air; and when the Plants are come up, and have gotten four or five Leaves, you ſhould prepare another Hot-bed to prick them into, which may be about two Inches ſquare; and in *April* harden them by degrees, to fit them for tranſplanting, which ſhould be done about the latter End of that Month at the Diſtances directed for the ſecond Crop, and muſt be manag'd accordingly: Theſe (if the Soil is moiſt where they are planted or the Seaſon cool and moiſt) will produce good *Cauliflowers* about a Month after the ſecond Crop is gone, whereby their Seaſon will be greatly prolong'd.

There is alſo a fourth Crop of *Cauliflowers*, which is rais'd by ſowing the Seed about the twelfth of *May*; and being tranſplanted, as hath been before directed, will produce good *Cauliflowers* in a kindly Seaſon, and good Soil after *Michaelmas*, and continue thro' *October* and *November*, and if the Seaſon permit, often a great part of *December*.

The Reaſon why I fix particular Days for the ſowing of this Seed, is, becauſe two or three Days often make a great Difference in their Plants; and becauſe theſe are the Days uſually fix'd by the Gardeners near *London*, who have found their Crops to ſucceed beſt when ſown at thoſe Times, although one Day ſooner or later will make no great Odds.

The Turnep Cabbage was formerly more cultivated in *England* than at preſent; for ſince other Sorts have been introduced which are much better flavoured, this Sort has been neglected. There are ſome Perſons who eſteem this Kind for Soups, but it is generally too ſtrong for moſt *Engliſh* Palates, and is ſeldom good but in hard Winters, which will render it tender, and leſs ſtrong.

It may be propagated by ſowing the Seeds in *March*, on a Bed of light freſh Earth and when the Plants are come up about an Inch high, they ſhould be tranſplanted out into a ſhady Border, at about two Inches diſtance every way, obſerving to water them until they have taken Root; after which time they will require no other Culture, but to keep them clear from Weeds, unleſs the Seaſon ſhould prove extremely dry; in which caſe it will be proper to water them every four or five Days to prevent their being ſtunted by the Mildew, which is ſubject to ſeize theſe Plants in very dry Weather.

The latter End of *May*, or the Beginning of *June*, theſe Plants ſhould be tranſplanted out where they are to remain, allowing them two Feet diſtance every way, obſerving to water them until they have taken Root; after which time they will require no other Culture but to keep them clear from Weeds; and as their Stems advance, ſo the Earth ſhould be drawn up to them with a Hough, which will preſerve the Earth moiſt about their Roots, and prevent their Stems from drying, and growing woody, ſo that the Plants will grow more freely. In Winter they will be fit for Uſe, when they ſhould be cut off, and the Stems pulled out of the Ground, and thrown away, as being good for nothing after the Heads are cut off.

The curled Colewort is more generally eſteemed than the former. This may be propagated by ſowing of the Seeds the Beginning of *July*, and when the Plants are ſtrong enough for tranſplanting, they ſhould be planted in Rows about eight or nine Inches aſunder, and four or five Inches diſtance in the Rows; this Work ſhould be performed at a moiſt time, when the Plants will ſoon take Root, and require no farther Care. Theſe will be fit for Uſe after *Chriſtmas*, and continue good until *April*, ſo that they are very uſeful in a Family.

The Muſk Cabbage has thro' Negligence been almoſt loſt in *England*, tho' for eating it is one of the beſt Kinds we have, but is tenderer than many other Sorts, ſo not profitable for Gardeners who ſupply the Markets; but thoſe who cultivate them for their own Table, ſhould make Choice of this, rather than any of the common Cabbage; for it is always looſer, and the Leaves more criſp and tender, and has a moſt agreeable muſky Scent when cut. This may be propagated in the ſame manner as the common Cabbage, and ſhould be allowed the ſame Diſtance. It will be fit for Uſe in *October*, *November*, and *December*; but if the Winter proves hard, theſe will be deſtroyed much ſooner than the common Sort.

The branching Sea-Cabbage is found wild in ſeveral Parts of *England*, on the Sea-coaſt, and is ſometimes gathered by the poor Inhabitants in the Spring, and eaten; but it is apt to be ſtrong and bitter, ſo that it is rarely cultivated for Uſe in the Gardens.

The brown Broccoli is by many Perſons greatly eſteemed, tho' it doth not deſerve a Place in the Kitchen-Garden, where the *Roman* Broccoli can be obtained, which is much ſweeter, and will continue longer in Seaſon. Indeed the brown Sort is much hardier, ſo that it will thrive in the coldeſt Situations, where the *Roman* Broccoli is ſometimes deſtroyed in very hard Winters. The brown Sort ſhould be ſown in *April*, and managed as hath been directed for the common Cabbage, and ſhould be planted at the ſame Diſtance (which is about two Feet and an half aſunder). This will grow very tall, ſo ſhould have the Earth drawn up to their Stems as they advance in Height. This doth not form Heads ſo perfect as the *Roman* Broccoli, ſo the Stems and Hearts of the Plants are the Part which is eaten.

The *Roman* Broccoli (if well managed) will have large Heads, which appear in the Centre of the Plants, like Cluſters of Buds. Theſe Heads ſhould be cut before they run up to Seed, with about four or five Inches of the Stems; the Skin of theſe Stems ſhould be ſtripp'd off, before they are boiled. Theſe will be very tender, and little inferior to *Aſparagus*. After the firſt Heads are cut off, there will be a great Number of Side-ſhoots produced from the Stems, which will have ſmall Heads to them, but are full as well flavoured as the large Heads. Theſe Shoots will continue good until the Middle of *April*, when the Aſparagus will come in Plenty to ſupply the Table.

Beſides this firſt Crop of Broccoli (which is uſually ſown the Middle or latter End of *May*) it will be proper to ſow another Crop the Beginning of *July*, which come in to ſupply the Table the latter End of *March*, and the Beginning of *April*; and being very young, will be extremely tender and ſweet.

In order to ſave good Seeds of this Kind of Broccoli in *England*, you ſhould reſerve a few of the largeſt Heads of the firſt Crop, which ſhould be let remain to run up to Seed, and all the Under-ſhoots ſhould be conſtantly ſtripp'd off, leaving only the main Stem to flower and ſeed. If this be duly obſerved, and no other Sort of Cabbage permitted to ſeed near them, the Seeds will be as good as thoſe procured from abroad, and the Sort may be preſerved in Perfection for many Years.

The common Colewort is now almoſt loſt near *London*, where their Markets are uſually ſupplied with Cabbage or Savoy Plants, inſtead of them, and thoſe being tenderer and more delicate are better worth cultivating than the common Colewort, which is ſtronger, and better able to reſiſt the Cold in ſevere Winters than either of thoſe, but is not near ſo delicate. And ſince the Winters in *England* have been generally temperate of late Years, ſo the common Cabbage and Savoy Plants have conſtantly been cultivated by the Gardeners near *London*, and ſold in the Markets as Coleworts. Indeed where Farmers ſow Coleworts to feed their Milch Cattle in the Spring, when there is a Scarcity of Herbage, the common Colewort is to be preferred, as being ſo very hardy, that no Froſt will deſtroy it.

The beſt Method to cultivate this Plant in the Fields, is, to ſow the Seeds about the Beginning of *July*, chuſing a moiſt Seaſon, which will bring up the Plants in about ten Days or a Fortnight; the Quantity of Seed for an Acre of Land is nine Pounds; when the Plants have gotten five or ſix Leaves, they ſhould be houghed, as is practiſed for Turneps, cutting down all the Weeds from amongſt the Plants, and alſo thinning the Plants where they are too thick; but they ſhould be left thicker than Turneps, becauſe they are more in danger of being deſtroyed by the Fly; this Work ſhould be performed in dry Weather, that the Weeds may be killed; for if it ſhould prove moiſt ſoon after, the Weeds will take Root again, and render the Work of little Uſe. About ſix Weeks after, the Plants ſhould have a ſecond houghing, which if carefully performed in dry Weather, will intirely deſtroy the Weeds, and make the Ground clean, ſo that they will require no farther Culture: in the Spring they may either be drawn up and carried out to feed the Cattle, or they may be turned in to feed them as they ſtand; but the former Method is to be preferred, becauſe there will be little Waſte, whereas when the Cattle are turned in amongſt the Plants, they will tread down and deſtroy more than they eat.

The perennial *Alpine* Colewort is alſo little cultivated in the Gardens near *London* at preſent. This is very hardy, and may be cultivated in the ſame Manner as the former Sort. This will continue two Years before it runs up to Seed, and will afterwards produce many Side-ſhoots, and in poor Land will continue three or four Years; but in rich Soils it will not laſt ſo long. This may be uſed as the former Sort to feed Cattle, for it is not ſo good for the Table as the Plants which are now cultivated for that Purpoſe.

The other two Sorts of wild Cabbage are Varieties fit for a botanick Garden; but are Plants of no Uſe. Theſe may be propagated by ſowing of their Seeds on a Bed of light Earth early in the Spring, in the Place where they are deſigned to remain (for they do not bear tranſplanting well): When the Plants are come up pretty ſtrong, they ſhould be thinn'd, ſo as to leave them four or five Inches apart, and they muſt be conſtantly kept clear from Weeds. In *June* they will flower; and their Seeds will ripen the Beginning of *Auguſt*, which if permitted to fall, the Plants will come up, and maintain themſelves without any farther Care but to keep them clear from Weeds. They are annual Plants, and periſh when they have perfected their Seeds.

BREYNIA.

This Plant was ſo named by Father *Plumier*, in Honour to Dr. *Breynius*, a learned Botaniſt at *Dantzick*, who publiſhed two Prodromus's to his Hiſtory of Plants, and one Century in Folio, in which the Plants are curiouſly delineated and engraven.

The *Characters* are;

It hath a Roſe-flower, conſiſting of many Petals, which are placed in a circular Order, from whoſe Flower-cup riſes the Pointal; which afterward becomes a Fruit or Pod, which is ſoft and fleſhy, in which are ſeveral Kidney-ſhap'd fleſhy Seeds.

The *Species* are;

1. **Breynia** *amygdali foliis latioribus. Plum. Nov. Gen.* Breynia, with broad Almond Leaves.

2. **Breynia** *elæagni foliis. Plum. Nov. Gen.* Breynia, with Leaves like thoſe of the wild Olive.

Both theſe Plants are very common in *Jamaica*, and ſeveral other Parts of *America*, where they uſually grow to the Height of thirty Feet; their Trunks are about the Thickneſs of a Man's Thigh, which are covered with a ſmooth Aſh-coloured Bark. The Branches come out on every Side, ſo as to form a regular Head, and being beſet with hoary Leaves, make an agreeable Appearance.

Theſe Plants are both very impatient of Cold, ſo muſt be preſerved in Stoves, otherwiſe they will not live thro' the Winter in this Climate. They may be propagated by Seeds, which may be obtained from *America*. Theſe Seeds ſhould be ſown on a Hot-bed early in the Spring, and when the Plants are come up two Inches high, they ſhould be carefully tranſplanted each into a ſeparate ſmall Pot, filled with light rich Earth, and then plunged into a moderate Hot-bed of Tanners-bark, obſerving to water and ſhade them until they have taken new Root; after which Time the Glaſſes of the Hot-bed ſhould be raiſed every Day in warm Weather, to admit freſh Air to the Plants, as alſo to let the Steam of the Bed paſs off; they muſt alſo be frequently watered during the Summer Seaſon, and when the Plants have grown ſo much as to fill the Pots with their Roots, they ſhould be carefully ſhaken out of them, and the Fibres round the Outſide of the Ball of Earth ſhould be carefully pared off, and then put into Pots a Size larger than thoſe they were in before, which ſhould be filled with light rich Earth, and then plunged into the Hot-bed again, obſerving to water them frequently in hot Weather, as alſo to admit freſh Air to them every Day. In this Bed they may remain until the End of *September*, when they muſt be placed in the Bark-ſtove, where during the Winter Seaſon they ſhould be kept in a temperate Heat, and muſt be often refreſhed with Water, but it muſt not be given to them in large Quantities at this Seaſon.

As theſe Plants increaſe in Bulk, ſo they ſhould be placed in larger Pots; but you muſt be very careful not to over-pot them, which will cauſe the Plants to decline, and if not timely remedied, will deſtroy them. In Summer theſe Plants ſhould have a large Share of freſh Air in warm Weather, but they muſt not be placed in the open Air; for if they are not conſtantly preſerved from the Cold, it will deſtroy them in a ſhort Time. If theſe Directions are duly obſerved, the Plants will make great Progreſs, and in a few Years will produce Flowers.

BROOM, the Common. *Vide* Cytiſo-Geniſta Scoparia.

BROOM, the *Spaniſh*. *Vide* Spartium & Geniſta.

BRUNELLA. Self-heal.

The *Characters* are;

The Flowers grow in ſhort compact Spikes, which conſiſt of one Leaf, and are labiated (or lip'd); the Creſt (or upper Lip) is intire and hollow'd; the Beard (or lower Lip) is divided into three Segments; the middle Segment is broad, and hollow, like a Spoon, and is farther produc'd than the two other Segments which are narrow; the Cup of the Flower hath two Lips; the upper being erect and trifid, and the lower is arm'd with two ſmall Spines.

There are ſeveral *Species* of this Plant preſerv'd in the curious Botanick Gardens: I ſhall mention the Varieties to be found in the *Engliſh* Gardens, and then give a ſhort Account of their Culture.

1. **Brunella** *major, folio non diſſecto. C. B.* Common Self-heal, with whole Leaves.

2. **Brunella** *major folio non diſſecto, flore albo. C. B* Common Self-heal, with white Flowers.

3. **Brunella** *folio laciniato. C. B.* Cut-leav'd Self-heal.

4. **Brunella** *folio laciniato, flore albo. H. R. P.* Cut-leav'd Self-heal, with white Flowers.

5. **Brunella** *cærulea, magno flore. C. B.* Large blue-flower'd Self-heal.

6. **Brunella** *Hyſſopifolia. C. B.* Narrow-leav'd Self-heal.

7. **Brunella** *Alpina laciniata, flore magno. Boerh. Ind.* Large-flower'd cut-leav'd Self-heal from the *Alps*.

8. **Brunella** *folio verbenæ tenuifoliæ. Boerh. Ind.* Self-heal, with Leaves like the narrow cut-leav'd *Vervain*.

9. **Brunella** *laciniata, flore elegantiſſime ſulphureo. Boerh. Ind.* Cut-leav'd Self-heal, with fine Sulphur-colour'd Flowers.

10. **Brunella** *latifolia Italica, flore carneo. Barrel.* Broad-leav'd *Italian* Self-heal, with Fleſh-colour'd Flowers.

11. **Brunella** *Novæ Angliæ major, foliis longius mucronatis. Rand. New-England* Self-heal, with long-pointed Leaves.

12. **Brunella** *Caroliniana magno flore dilute cæruleo internodiis longiſſimis. Rand. Carolina* Self-heal, with large pale blue Flowers, and long Spaces between the Joints of the Stalks.

Theſe Plants may be any of them propagated by ſowing their Seeds in the *Spring* of the Year, on a Bed of common Earth, and when they are come up, may be planted out in Borders in any ſhady Part of the Garden, where they will thrive, and many of them flower the ſame Year, but all of them the ſecond, after which they ſeldom continue; therefore the Seeds of them muſt be ſown yearly for a freſh Supply.

The firſt Sort is uſed in Medicine, and is very common in divers Parts of *England*: The others are of foreign Growth; and although there is not a great deal of Beauty in them, yet ſome of the Varieties are worth cultivating to add to the Diverſity, eſpecially ſince they require very little Culture.

BRUNSFELSIA. This Plant takes its Name from Dr. *Brunſfelſius*, a famous Phyſician.

The *Characters* are;

The Flower conſiſts of one Leaf ſhap'd like a Funnel, which is tubulous, and cut into many Parts at the Top; from whoſe Calyx ariſes the Pointal, which afterwards becomes a round, ſoft, fleſhy Fruit, containing roundiſh Seeds between the Rind and the Fleſh.

We have but one *Species* of this Plant, which is;

Brunsfelsia *flore albo, fructu croceo molli. Plum. N. G.* Brunsfelſia with a white Flower, and a ſoft ſaffron-coloured Fruit.

This Plant is very common in *Barbadoes* and *Jamaica*, but in *Europe* it is at preſent very rare: It may be propagated from Seeds, which ſhould be ſown early in the Spring, in Pots filled with light Earth, and plunged into a Hot-bed of Tanners-bark; obſerving to water the Earth as often as you find it neceſſary. When the Plants are come up, they ſhould be tranſplanted each into a ſeparate ſmall Pot, filled with freſh light Earth, and plunged into the Hot-bed again; obſerving to water and ſhade the Plants until they have taken Root; after which, they ſhould have Air let into the Hot-bed, in proportion to the Warmth of the Seaſon, and the Bed into which they are placed; and they muſt be frequently refreſhed with Water. When the Plants have advanced ſo high as not to be contained in the Frames, they ſhould be removed into the Bark-ſtove; where, during the Summer Months, they ſhould have a large Share of free Air; but in Winter they muſt be kept very cloſe. With this Management the Plants will be very ſtrong, and produce their Flowers every Seaſon. Theſe Plants may alſo be increaſed by planting their Cuttings in the Spring before they put out, in Pots filled with freſh light Earth, and plunged into a Hot-bed of Tanners-bark, obſerving to water and ſhade them until they have taken Root; after which they muſt be managed as hath been directed for the ſeedling Plants.

BRUSCUS. *Vide* Ruſcus.

BRYONIA; [This Plant is ſo call'd of βρύω, ſignifying to ſhoot or ſpring, becauſe it is a Plant of luxuriant Growth] Briony.

The *Character* is;

It hath a climbing Stalk with Spines; the Leaves are like thoſe of the Vine; *the Flowers conſiſt of one Leaf, which is expanded at the Top, and divided into five Parts; and in the Female Plants are ſucceeded by round Berries growing on Footſtalks; the Flowers of the Male Plants have five Apices in each, but are barren.*

The *Species* are;

1. Bryonia *aſpera ſive alba, baccis rubris. C. B.* The common white Briony.
2. Bryonia *Africana glabra, foliis in profundas lacinias diviſis, flore luteo. Olden.* Smooth *African* Briony with deep cut Leaves and yellow Flowers.
3. Bryonia *Americana, Olivæ fructu rubro. Plum. Cat. American* Briony with a red Olive ſhap'd Fruit.
4. Bryonia *Africana, fructu variegato. Hort. Elth. African* Briony with a variegated Fruit.
5. Bryonia *Africana laciniata, tuberoſa radice, floribus herbaceis. Par. Bat. African* cut-leav'd Briony with a tuberoſe Root and herbaceous Flowers.

The firſt Sort grows upon dry Banks under Hedges in many Parts of *England*, but may be cultivated in a Garden for Uſe, by ſowing the Berries in the Spring of the Year in a dry poor Soil, where they will in two Years Time grow to be large Roots, provided they are not too thick. The Roots of this Plant have been formerly cut into an human Shape, and carry'd about the Country, and ſhewn for *Mandrakes* by a Parcel of idle People, who very eaſily impos'd on the Credulity of the common People, and got good Livings thereby. The Leaves of this Plant are alſo often impo'd on the People in the Market for *Mandrake* Leaves, altho' there is no Reſemblance between them, nor any Agreement in Quality.

The ſecond and fifth Sorts are perennial Plants, their Roots remaining ſeveral Years, but their Branches decay every Winter. Theſe Roots muſt be planted in Pots filled with freſh light Earth, and in Winter muſt be placed in the Greenhouſe, to protect them from Froſt and great Rains, which would deſtroy them if they were expos'd thereto. During the Winter Seaſon they ſhould have very little Water given to them; but in Summer when they are expoſed to the open Air, they muſt be frequently refreſhed with Water in dry Weather. Theſe Plants will flower in *July*, and in warm Summers will perfect their Seeds.

The third and fourth Sorts are annual Plants; theſe muſt be raiſed on a Hot-bed early in the Spring, and when the Plants are about three Inches high, they ſhould be each tranſplanted into a ſmall Pot filled with freſh light Earth, and plunged into a Hot-bed of Tanners-bark, obſerving to water and ſhade 'em until they have taken Root, after which Time they ſhould have Air let into the Bed every Day, in proportion to the Warmth of the Seaſon. When the Plants are grown ſo large, as to ramble about on the Surface of the Bed, and begin to entangle with other Plants, they ſhould be ſhifted into larger Pots, and placed in the Bark-ſtove, where their Branches may be trailed to the Wall, or againſt an Eſpalier, that they may have Sun and Air, which is abſolutely neceſſary for their producing Fruit. When theſe Plants are full of Fruit, they make a very pretty Variety in the Stove amongſt other exotick Plants.

The ſecond and fifth Sorts are alſo propagated from Seeds, which ſhould be ſown on a Hot-bed, and when the Plants are fit to tranſplant, they ſhould be put into Pots, and after they have taken Root, ſhould be inured to bear the open Air by degrees.

The Briony being Male and Female in different Plants, induced me to make ſome Experiments with it, to confirm my Opinion of the Neceſſity of the Female Plant being impregnated by the Farina of the Male Plant, in order to render it fruitful. Accordingly I planted a Female Briony in a Garden, wherein there was no Male Plant of that Kind, nor in any of the neighbouring Parts, as I could diſcover; but, contrary to my Expectation, this Plant produced ripe Fruit, which I ſowed ſoon after it was ripe, and the Spring following I had a great Number of young Plants came up. The following Year I was more curious to try the Experiment, and examined all the neighbouring Parts again, to ſee if I could diſcover any Male Plants, but could not; yet the Succeſs was the ſame as the former Year, and the Plants which aroſe from the Seeds grew very ſtrong and vigorous. So that this and many other Experiments ſhould be frequently repeated, and carefully examined, before we can pronounce any Thing for Certainty concerning the Generation of Plants.

BRYONIA NIGRA. *Vide* Tamnus.

BUCKSHORN or HARTSHORN. *Vide* Coronopus.

BUGLOSSUM, [Βȣ̃γλωσσος, of βȣ̃ς, an *Ox*, and γλῶσσα, a *Tongue*, q. d. *Ox-Tongue*, becauſe the Leaves of this Plant imitate the Tongue of an Ox in their Shape and Roughneſs] Bugloſs.

The *Characters* are;

The Flowers are ſmall and tubulous, divided at the Top into five obtuſe Segments, and are expanded in a round Form; the Seeds are like the Head of a Viper.

The *Species* are;

1. Buglossum *perenne majus ſativum. M. H.* The Garden Bugloſs.
2. Buglossum *ſylveſtre minus. C. B.* The leſſer wild Bugloſs.
3. Buglossum *latifolium ſemper-virens. C. B.* The broad-leav'd ever-green Bugloſs.
4. Buglossum *Orientale flore luteo. T. Cor.* The Eaſtern Bugloſs, with yellow Flowers.
5. Buglossum *Creticum verrucoſum perlatum quibuſdam. H. R. Par.* Warted Bugloſs from *Crete*.
6. Buglossum *anguſtifolium majus, flore albo. C. B. P.* Greater narrow-leav'd Bugloſs, with a white Flower.
7. Buglossum *anguſtifolium majus, flore rubro aut variegato. C. B. P.* Greater narrow-leav'd Bugloſs, with a red or variegated Flower.
8. Buglossum *foliis ſinuoſis. C. B. P.* Bugloſs, with ſinuated Leaves.
9. Buglossum *ſylveſtre majus nigrum. C. B. P.* Greater wild black Bugloſs.
10. Buglossum *Creticum majus, flore cœruleo purpurante. H. R. Par.* Greater Bugloſs of *Candy*, with a blue Flower, inclining to a purple Colour.
11. Buglossum *Luſitanicum, echii folio undulato. Inſt. R. H. Portugal* Bugloſs, with an undulated Vipers Bugloſs Leaf.
12. Buglossum *Creticum minimum odoratum, flore vario eleganti. H. R. Par.* The leaſt ſweet-ſcented *Candy* Bugloſs, with an elegant Flower of various Colours.
13. Buglossum *Creticum humifuſum acaulon perenne, echii folio anguſtiſſimo. Tourn. Cor.* Perennial *Candy* Bugloſs, lying ſpread upon the Ground without Stalks, and with a very narrow Vipers Bugloſs Leaf.
14. Buglossum *Samium fruteſcens, foliis roriſmarini obſcure virentibus, lucide hirſutis. Tourn. Cor.* Shrubby Bugloſs from the Iſland of *Samos*, with Roſemary Leaves of a ſhining dark green Colour, and hairy.
15. Buglossum *orientale erectum, foliis undulatis, flore amœne cœruleo. Tourn. Cor.* Upright Eaſtern Bugloſs, with undulated Leaves, and a Flower of a beautiful blue Colour.
16. Buglossum *orientale anguſtifolium, altiſſimum. Tourn. Cor.* The talleſt Eaſtern Bugloſs, with narrow Leaves.

Theſe may be cultivated, by ſowing their Seeds in the Spring, in Beds of common undung'd Earth, and may be afterwards tranſplanted, where they are to remain: They all delight in a dry poor Soil.

The firſt Sort is cultivated for its Flowers, which are uſed in Medicinal Cordials. The ſecond Sort grows wild upon dry Banks, in moſt Parts of *England*, and is ſometimes uſed in Medicine. The third Sort is always green, and may have a Place in ſhady Wilderneſſes, but is not fit for a fine Garden. The fourth Sort is an abiding Plant, and may deſerve a Place in a good Garden, for its long Continuance to flower. The fifth Sort is an Annual, and if ſuffer'd to ſow itſelf, will come up and abide the Winter very well, and produce its ſmall blue Flowers in the Spring. The fourth and fifth Sorts for their Variety, may have a Place in the Flower Garden, and the firſt Sort in the Phyſick Garden, for its Uſe.

The ſixth and ſeventh Sorts here mentioned are Varieties of the Garden Bugloſs. Theſe are preſerved in botanick Gardens for the ſake of Variety, and may be cultivated in the ſame manner as hath been above directed, as may alſo the eighth, ninth, tenth, and eleventh Sorts, which are all hardy, and produce good Seeds in this Climate.

The twelfth Sort is an annual Plant of an humble Growth, which ſeldom riſes above three or four Inches high, but ſhoots out ſeveral Side-branches, which ſpread near the Surface of the Ground; at the Extremity of theſe Branches the Flowers are produced, which are of a beautiful red Colour, ſtriped with white. This may be propagated by Seeds, which ſhould be ſown on a Bed of light freſh Earth, in the Place where it is deſigned to remain; becauſe it doth not bear tranſplanting. When the Plants are come up, they ſhould be cleared from Weeds; and where the Plants are too cloſe together, they muſt be thinned, leaving them four or five Inches apart; after this they will require no farther Care, but to keep them conſtantly clear from Weeds. In *June* they will flower, and their Seeds will ripen in *Auguſt*, which if permitted to fall, will produce Plants in Autumn, which will abide thro' the Winter; and theſe autumnal Plants will be much ſtronger, and produce a greater Number of Flowers than thoſe which are ſown in the Spring.

The thirteenth and fourteenth Sorts are perennial Plants, which are ſomewhat tenderer than either of the former. Theſe are propagated by Seeds, which ſhould be ſown on a warm Border of light freſh ſandy Earth, early in the Spring, and when the Plants begin to appear, you muſt carefully clear 'em from Weeds, and where they are too cloſe to each other you muſt draw out ſome of them, which may be tranſplanted into Pots filled with light freſh Earth, which may be placed under a common Hot-bed Frame in Winter, to protect them from hard Froſt; for in ſevere Winters moſt of the Plants in the open Air will be deſtroyed, ſo that, unleſs you have ſome Plants in ſhelter, you may intirely loſe the Kinds. Thoſe Plants which are left in the Border where they were ſown ſhould be thinned, ſo as to leave them about eighteen Inches aſunder, and muſt be conſtantly kept clean from Weeds, which is all the Culture they will require. The ſecond Year they will produce Flowers and Seeds, but will continue ſeveral Years after, eſpecially if they are in a dry rubbiſhy Soil, which is poor; for in a moiſt rich Earth they will grow very luxuriant in Summer, but are generally deſtroyed with the firſt Approach of Winter. Theſe generally ſend forth tap Roots, which run very deep in the Ground, ſo will not bear tranſplanting well, when they have acquired much Strength. The thirteenth Sort is a very low ſpreading Plant, ſo ſhould be allowed more Room than the fourteenth, which grows upright, and becomes ſhrubby.

The fifteenth and ſixteenth Sorts are biennial Plants, which ſeldom abide after they have perfected their Seeds, which is uſually the ſecond Year after they were ſown. Theſe Plants are propagated by Seeds, in the ſame manner as the common Bugloſs, but ſhould have a warmer Situation, and a drier Soil, otherwiſe they will not live thro' the Winter in this Climate; therefore it will be proper to plant a few of theſe Plants into Pots while they are young, that they may be ſheltered under a common Frame in Winter; and if the Spring following they are ſhaken out of the Pots carefully, ſo as to preſerve the Earth about their Roots, and planted in a Bed of freſh Earth, they will grow much ſtronger, and produce a greater Number of Flowers, than if they remain in the Pots. But theſe Plants having tap Roots will not bear tranſplanting any better than the two former Sorts.

BUGULA; Bugle.

The *Characters* are;

It hath a Flower conſiſting of one Leaf, with one Lip divided into three Parts, the Middle of which is ſplit into two: The Place of the under Lip is ſupplied by ſmall Teeth. Out of the Flower-cup riſes the Pointal, fixed like a Nail into the hinder Part of the Flower, and attended, as it were, by four Embryo's, which afterwards become ſo many oblong Seeds, ſhut up in a Huſk, which before was the Flower-cup. To theſe Notes may be added, that the Flowers are placed in Whorles round the Stalks.

The *Species* are;

1. BUGULA. *Dod. pempt.* Common Bugle.
2. BUGULA *flore cinereo vel albo. Inſt. R. H.* Bugle with a white or aſh-colour'd Flower.
3. BUGULA *Alpina maxima. Inſt. R. H.* The greateſt Bugle of the *Alps*.
4. BUGULA *ſylveſtris villoſa, flore cæruleo. Inſt. R. H.* Hairy Wood Bugle with a blue Flower.
5. BUGULA *ſylveſtris villoſa, flore ſuaverubente. Inſt. R. H.* Hairy Wood Bugle, with a fine red Flower.
6. BUGULA *ſylveſtris villoſa, flore albo. Inſt. R. H.* Hairy Wood Bugle, with a white Flower.
7. BUGULA *Samia verna, boraginis folio, flore inverſo, & cæruleo flaveſcente. Tourn. Cor.* *Samian* Spring Bugle, with a borage Leaf, and an inverted Flower of a yellowiſh blue Colour.
8. BUGULA *orientalis villoſa, flore inverſo cæruleo, alba macula notato. Tourn. Cor.* Hairy Eaſtern Bugle, with an inverted blue Flower, ſpotted with White.
9. BUGULA *orientalis villoſa, flore inverſo candido, cum oris purpureis. Tourn. Cor.* Hairy Eaſtern Bugle, with an inverted white Flower, edged with Purple.
10. BUGULA *orientalis, flore ex violaceo purpuraſcente. Tourn. Cor.* Eaſtern Bugle, with a purpliſh Violet-colour'd Flower.
11. BUGULA *orientalis longifolia, flore majore intenſe cæruleo. Tourn. Cor.* Eaſtern Bugle, with a long Leaf, and a larger Flower, of an intenſe blue Colour.

The firſt and ſecond Sorts grow wild in moiſt Woods and Meadows in moſt Parts of *England*, and continue in Flower from *May* to *September*. Theſe Plants propagate themſelves greatly by their creeping Stalks, which ſend forth Roots at every Joint, ſo that where they have room to ſpread, they will make a great Increaſe; but they are ſeldom preſerved in Gardens.

The Bugle is greatly eſteemed as a vulnerary Herb, and is uſed both internally and externally; it enters as an Ingredient into the vulnerary Decoctions of the Surgeons, and is commended, externally applied to Ulcers.

The third, fourth, fifth, and ſixth Sorts are preſerved in botanick Gardens for the ſake of Variety; theſe are very hardy Plants, and propagate greatly by their trailing Stalks, as the common Sort. They muſt have a moiſt Soil, and a ſhady Situation, where they will thrive exceedingly, without any other Culture, but to keep them clear from Weeds.

The ſeventh, eighth, ninth, tenth, and eleventh Sorts were diſcovered by Dr. *Tournefort* in the *Levant*, who ſent their Seeds to the Royal Garden at *Paris*, where they were propagated firſt in *Europe*, and from thence ſeveral other Gardens have been ſupplied with theſe Plants. They may be propagated by Seeds, which ſhould be ſown on a ſhady Border, and a light moiſt Soil early in the Spring; and when the Plants begin to appear, they ſhould be carefully cleared from Weeds, and in dry Weather muſt be frequently watered, otherwiſe they will not make any great Progreſs. When the Plants have acquired Strength enough to be removed, they ſhould be tranſplanted, ſome into Pots, and the reſt into a ſhady moiſt Border, where they may remain to flower. Thoſe which are put into Pots ſhould have a ſhady Situation during the Summer Seaſon, and muſt be frequently watered in dry Weather, but in Winter they ſhould be placed under a Hot-bed Frame, where they may be protected in ſharp Froſts, but in mild Weather they ſhould have as much free Air as poſſible, for they are ſo hardy as to endure the Cold of our ordinary Winters very well in the open Air without any Shelter.

Theſe Plants may alſo be multiplied by parting of their Roots in the Spring, after the Manner of the *Auricula*; but you muſt be careful not to part them too ſmall, leſt you deſtroy them; for if each Head hath not good Roots, they ſeldom ſucceed, ſo that they are not to be increaſed very faſt in this Method.

BULB, [*Bulbus*, Lat. of βόλβος, Gr.] A Bulbous Root conſiſts of many Coats incloſed one within another, or join'd together by many Scales diſpoſed in an imbricated Manner, and is of an orbicular Form, ſending forth many Fibres from its Baſe. Of this Claſs are *Onions*, *Tulips*, &c.

BULBOCASTANUM; Earth-Nut, or Pig-Nut.

The *Characters* are;

It is an umbelliferous Plant, with a Roſe-ſhaped Flower, conſiſting of many Leaves, placed orbicularly, and ſitting on the Empalement; which turns to a Fruit compoſed of ſmall oblong ſmooth Seeds, which are ſometimes channelled, gibbous on one Side, but plain on the other. To theſe Notes muſt be added, a fleſhy tuberous Root.

The *Species* are;

1. BULBOCASTANUM *majus, folio apii. C. B. P.* Greater Earth-Nut, with a parſley Leaf.
2. BULBOCASTANUM *minus ſaxatile, peucedani folio. Tourn.* Smaller Rock Earth-Nut, with a Swines Fennel Leaf.
3. BULBOCASTANUM *majus Alpinum, paſtinacæ folio.* Greater Alpine Earth-Nut, with a Parſnip Leaf.
4. BULBOCASTANUM *tenuiter inciſo folio, luſitanicum. Tourn.* Portugal Earth-Nut, with a fine cut Leaf.
5. BULBOCASTANUM *Creticum, radice napiformi. Tourn. Cor.* Candy Earth-Nut, with a Navew Root.
6. BULBOCASTANUM *Creticum, ferulæ folio, ſemine oblongo. Tourn. Cor.* Candy Earth-Nut, with a Giant Fennel Leaf, and oblong Seeds.

The firſt Sort is very common in ſhady Woods and Paſtures in divers Parts of *England*, it riſes early in the Spring, and flowers in *May*. In *July* the Seeds are ripe, ſoon after which time the green Leaves begin to decay, which is the proper Seaſon to take up the Roots for Uſe, becauſe they may be more readily found before their Leaves are quite decayed; and if they are taken up, while the Plants are in Vigour, the Roots will be ſmall, and not near ſo firm. Some People dig up theſe

Roots, and eat them raw, which taſte very much like Cheſnuts, and are no unpleaſant Morſel; but when they are boiled, they are a very delicious Food, eaten with Butter and Pepper, and are eſteemed very nouriſhing.

The other Sorts are not Natives of *England*, ſo are rarely to be found except in botanick Gardens, where they are preſerved for the ſake of Variety, more than any Beauty there is in their Appearance.

They are all very hardy Plants in reſpect to Cold, ſo may be eaſily propagated by ſowing of their Seeds on a moiſt ſhady Border, ſoon after they are ripe (for if they are kept out of the Ground till Spring, they ſeldom ſucceed ſo well as when they are ſown in Autumn). When the Plants appear in the Spring, they muſt be carefully cleared from Weeds, and where they are too near, they ſhould be thinned, ſo as to leave them three or four Inches aſunder; after this they will require no other Culture, but to keep them clear from Weeds; for they do not bear tranſplanting, ſo muſt be ſown where they are to remain. The Autumn following the Roots will be fit for Uſe, and will continue good all the Winter, till they ſhoot up all their Stems in the Spring for Seed, after which time they are tough, and not fit for eating.

BULBOCODIUM, [of *Bulbus*, a Bulb, and *Codium*.]

The *Characters* are;

The Flowers conſiſt of one Leaf, and are divided into ſix Segments, being in Shape like the Crocus *Flower; the Leaves are very long and narrow; the Root conſiſts of ſolid Bulbs, one over the other, which are cloſely join'd.*

We have but one *Species* of this Plant in the *Engliſh* Gardens, which is,

Bulbocodium *croci folio, flore parvo violaceo. T. Cor.* Bulbocodium with Leaves like the Saffron, and ſmall Violet-colour'd Flowers.

This Plant is cultivated after the Manner of the Spring *Crocus's*, *viz.* by parting its Bulbs, or ſowing the Seeds: It is commonly three or four Years before it comes to flower from Seed; but as it increaſes but ſlowly by the Root, ſo we muſt ſow the Seeds, if we intend to have a Stock of this Plant: It flowers in *April*, and the Seeds are ripe in *June*, and ſhould be ſown ſoon after in Pots of common Earth, where they ſhould remain two Years undiſturb'd, and then may be planted out into a Border at about three Inches ſquare, where they may ſtand to flower: It is alſo very probable, that ſome other Colours may be obtain'd by ſowing the Seeds, as we find is often the Caſe with moſt other Bulbs, when raiſed from Seeds.

BUPHTHALMUM, [Βȣφθαλμὸς, of Βοῦς, an *Ox* or *Bull*, and ὀφθαλμὸς an *Eye*; q. d. an *Ox Eye*, becauſe the Flower reſembles an Eye] Ox-Eye.

The *Characters* are;

The whole Face of the Plant is like Tanſy; the Flowers, which are radiated, are, for the moſt part, produced ſimply; the Florets of the Disk are ſeparated with an imbricated little Leaf.

The *Species* are;

1. **Buphthalmum** *tanaceti minoris folio. C. B.* The common Ox-eye, with Leaves like Tanſy.
2. **Buphthalmum** *Orientale, tanaceti minoris folio, flore luteo ampliſſimo. T. Cor.* The Eaſtern Ox-eye, with large yellow Flowers.
3. **Buphthalmum** *Orientale, tanaceti minoris folio, flore albo ampliſſimo. T. Cor.* The Eaſtern Ox-eye, with large white Flowers.
4. **Buphthalmum** *tanaceti minoris folio incano, flore ſulphureo ampliſſimo. Boer. Ind.* Ox-eye with hoary Tanſy Leaves, and large Sulphur-colour'd Flowers.
5. **Buphthalmum** *Creticum, cotulæ folio. Breyn. Cent.* 1. Ox-eye from *Crete*, with a *May-weed* Leaf.

The firſt of theſe Plants is mention'd by Mr. *Ray* as a Native of *England*, but is rarely found wild with us. The other two were found by Monſ. *Tournefort*, in the *Levant*. Theſe are propagated by ſowing their Seeds in *March*, in a Bed of light Earth; and when they are come up, may be tranſplanted into Borders of the Flower-Garden, or in little Wilderneſs Knots. Theſe Plants do continue flowering almoſt all the Summer long; for which they deſerve a Place in every good Garden. The Flowers are very proper to gather for Flower-pots, to adorn Rooms and Chimnies in the Summer Seaſon.

They delight in a dry Soil, and ſuch as is not much dung'd; and may alſo be increaſed by parting their Roots at *Michaelmas*, or early in the Spring. The firſt Sort is ſometimes uſed in Medicine.

The fourth Sort was ſent from *Auſtria* to the learned Dr. *Boerhaave*, at *Leyden*: This is ſo nearly akin to the two Eaſtern Sorts, as not to be diſtinguiſhed therefrom, but by their hoary Leaves, and the Colour of the Flower: It muſt be treated in the ſame Manner as hath been directed for them.

The fifth Sort is an annual Plant: this is propagated from Seeds, which ſhould be ſown on a Bed of light freſh Earth, and when the Plants are come up two Inches high, they ſhould be tranſplanted where they are to remain to flower, where they muſt be allowed at leaſt a Foot, to ſpread their Branches: they require no other Care, but keep them clear from Weeds: In *July* they will flower, and in Autumn they perfect their Seeds. Some Botanick Authors have mentioned three or four Varieties of this Plant, one with a naked Flower, another with very ſmall Rays, and one with large Rays; but theſe Varieties will all come from the ſame Seeds, as I have frequently experienced.

BUPLEUROIDES: [of Βοῦς, πλευρὸν and εἶδος, *Form* or *Shape*] *See* Bupleurum.

The *Characters* are;

The Leaves grow together by two's and three's in the ſame Place; the End of the Foot-ſtalk bears an oblong Ovary, the Apex of which is crown'd with a naked, herbaceous, pentapetalous Flower, the Petals being rolled up, incloſing five Stamina; the Ovary has a Tube cleft in two, the Apices of which are backwards, and rough; when ripe, it paſſes into two longiſh Seeds; the Flowers are diſpoſed in the Form of an Umbel or Umbrella.

Bupleuroides, *quæ ſimpla nobla Canarienſium. Pluk. Alm.*

There is at preſent but this one *Species* of this Plant known; it was formerly growing in many *Engliſh* Gardens, but was intirely loſt in the Gardens near *London*, till in 1727. I brought it over from *Holland* again. It is a Plant of no great Beauty; but as it is an Ever-green, may be kept, to add to the Variety in the Green-houſe. It is pretty hardy, and will endure our Winters with very little Shelter; and is propagated by ſowing of the Seeds in *March*, in a Bed of common Earth, where they will eaſily come up, and may be afterwards tranſplanted into Pots, in order to remove them in Winter into Shelter. They require to be often water'd, and love open Air.

BUPLEURUM, [Βούπλευρον, of Βοῦς, an *Ox*, and πλευρὸν a *Side*, becauſe it is ſaid to cauſe a Crepitation of the Side of an Ox; but more probably, becauſe it affords the Ox a Bed: Or it may be ſuppoſed to be ſo call'd, becauſe the Leaves bear ſome Reſemblance to the Rib of an Ox; or of Βοῦ, *great*, and πλευρὸν, *Side*, as tho' Large Rib] Hare's-ear.

The *Characters* are;

The Leaves grow alternately upon the Branches; and, for the moſt part, ſurround the Stalk, having no Foot-ſtalk: the Seeds are oblong, ſmooth, and furrow'd.

The *Species* are;

1. **Bupleurum** *arboreſcens, folio ſalicis. Tourn. Seſeli Æthiopicum, frutex. Dod.* The ſhrubby Hartworth of *Æthiopia.*
2. **Bupleurum** *folio rigido. C. B. P.* Stiff-leav'd Hare's Ear.
3. **Bupleurum** *folio ſubrotundo, ſive vulgatiſſimum. Tourn.* The moſt common round-leav'd Hare's Ear.
4. **Bupleurum** *annuum anguſtifolium. Bot. Monſp.* Narrow-leav'd annual Hare's Ear.
5. **Bupleurum** *annuum minimum anguſtifolium. H. R. Par.* The leaſt narrow-leav'd annual Hare's Ear.
6. **Bupleurum** *anguſtiſſimo folio. C. B. P.* Very narrow-leav'd Hare's Ear.
7. **Bupleurum** *perfoliatum rotundifolium annuum. Tourn.* Annual round-leav'd Hare's Ear, commonly called Thorough-wax.
8. **Bupleurum** *perfoliatum longifolium annuum. Tourn.* Annual long-leav'd perfoliated Hare's Ear.
9. **Bupleurum** *montanum latifolium. Tourn.* Broad-leav'd mountain Hare's Ear.
10. **Bupleurum** *montanum, floſculis exiguis. Tourn.* Mountain Hare's Ear, with ſmall Flowers.

11. Bupleurum *Alpinum latifolium minus. Tourn.* Smaller broad-leav'd Hare's Ear of the *Alps.*

12. Bupleurum *Alpinum anguſtifolium majus. Tourn.* Greater narrow-leav'd Hare's Ear of the *Alps.*

13. Bupleurum *Alpinum anguſtifolium minus. Tourn.* Smaller narrow-leav'd Hare's Ear of the *Alps.*

14. Bupleurum *montanum, gramineo folio. Tourn.* Mountain Hare's Ear, with a graſs Leaf.

15. Bupleurum *Hiſpanicum arboreſcens, gramineo folio. Tourn.* Spaniſh Tree Hare's Ear, with a graſs Leaf.

16. Bupleurum *Hiſpanicum fruticoſum aculeatum, gramineo folio. Tourn.* Prickly *Spaniſh* Shrub Hare's Ear, with a graſs Leaf.

17. Bupleurum *Luſitanicum, gramineo longiori & rigidiſſimo folio. Tourn.* Portugal Hare's Ear, with a long rigid graſs Leaf.

18. Bupleurum *Orientale anguſtifolium, ſemine longiori. Tourn. Cor.* Narrow-leav'd Eaſtern Hare's Ear, with a longer Seed.

This is a ſhrubby Plant, commonly growing to the Height of ſix or ſeven Feet, and divides into many Branches; the Leaves, which are ever-green, are ſomewhat like thoſe of the broad-leav'd Willow, but much thicker. This Shrub is hardy, and will endure our ſevereſt Winters in the open Air, provided it is planted in a dry Soil. This may be increaſed by ſowing the Seeds in Autumn, ſo ſoon as they are ripe, in a Pot of common Earth, which ſhould be put under Shelter in very cold Weather, but not kept too dry: In the Spring following, the Seeds will come, and when the young Plants have acquired a little Strength, they may be planted in a Border a little defended from cold Winds, where they may continue for a Year or two, and then be removed where they are deſigned to remain. The Cuttings of this Tree will alſo take Root; but this being a leſs certain Method than the other, and as the Plant produces large Quantities of Seeds, it is hardly worth the Trial.

The ſixth and ſeventh Sorts are Natives of *England*, and grow on cultivated Places amongſt the Corn in ſeveral Counties. The ſeventh Sort is placed amongſt the medicinal Plants in the College Diſpenſatory, but is rarely uſed, tho' it has been formerly eſteemed as a vulnerary Herb.

All theſe Sorts (excepting the fifteenth and ſixteenth are biennial Plants, which are extremely hardy, and may be propagated by ſowing of their Seeds in Autumn, upon a Bed of freſh Earth, in almoſt any Situation, but they thrive beſt in the Shade. When the Plants are come up, they ſhould be thinned where they come up too thick, and cleared from Weeds, which is all the Culture theſe Plants require; for if they are permitted to ſhed their Seeds, the Plants will come up, and maintain themſelves without any Care.

The fifteenth and ſixteenth Sorts are perennial Plants, which riſe to the Height of ſix or ſeven Feet. Theſe may be propagated by ſowing their Seeds on a ſhady Border in Autumn, and when the Plants begin to appear, they ſhould be cleared from Weeds, and in dry Weather they muſt be watered, which will greatly promote their Growth. When they are two Inches high, they ſhould be tranſplanted into a Border at about ſix or eight Inches diſtance, obſerving to water and ſhade them until they have taken new Root; after which time they will require no farther Care, but to keep them clear from Weeds, and in very dry Weather to refreſh them now and then with a little Water. In this Bed they may remain until the Beginning of *September*, when they ſhould be carefully taken up, with a Ball of Earth to their Roots, and ſome of them planted amongſt Shrubs in ſmall Wilderneſs Quarters, where they will add to the Variety; but there ſhould be a few planted into Pots, that they may be placed under a Frame in Winter, to ſhelter them from hard Froſts, which will often deſtroy them while they are young; but when they have acquired Strength, they will endure the Cold of our ordinary Winters very well.

BURNET: *vide* Pimpinella.

BURSA PASTORIS, Shepherds-Pouch. This is a common Weed in moſt Parts of *England.*

BUTOMUS, [Βούτομον, of Βοῦς, an *Ox*, and τέμνω, *to cut*, ſo call'd, becauſe the Leaves of it are ſo accute, that the Tongue and Lips of Oxen, who are great Lovers of this Plant, are wounded by it, ſo that the Blood iſſues forth: It is alſo call'd *Juncus Florida*, becauſe it has the Leaves of a *Bulruſh.*] The Flowering Ruſh *or* Water Gladiole.

The *Characters* are;

The Leaves are triangular and graſſy; the Stalks are naked; the Flowers are diſpoſed in an Umbel upon the Top of the Stalk, and each conſiſts of ſix Leaves; three of them are large, and three ſmall, which are expanded in Form of a Roſe.

The *Species* are;

1. Butomus *flore roſeo. Tourn.* The Roſe-colour'd Flowering Ruſh.

2. Butomus *flore albo. Tourn.* The White Flowering Ruſh.

3. Butomus *flore ſaturate purpureo. Boerh. Ind.* The deep Purple-colour'd Flowering Ruſh.

The firſt of theſe Varieties is pretty common in ſtanding Waters, in many Parts of *England*; the other two are Varieties of this, tho' leſs common with us. Theſe Plants may be propagated in boggy Places, or by planting them in Ciſterns, which ſhould be kept fill'd with Water, that ſhould have about a Foot Thickneſs of Earth in the Bottom: Theſe, tho' common Plants, yet produce very pretty Flowers, and are worth propagating for Variety ſake, eſpecially if in any Part of the Garden there ſhould be Conveniency for an artificial Bog, as is many times the Caſe, and Perſons are at a Loſs what to plant in ſuch Places, that may appear beautiful; whereas, if theſe and a few more wild Plants, which naturally grow in ſuch Places, were taken into the Garden, they would have a very good Effect in diverſifying the ſeveral Parts thereof.

BUXUS, The Box-tree.

The *Characters* are;

The Leaves are pennated, and ever-green; it hath Male Flowers, which are produced at remote Diſtances from the Fruit on the ſame Tree; the Fruit is ſhaped like a Porridge-pot inverted, and is divided into three Cells, containing two Seeds in each; which, when ripe, are caſt forth by the Elaſticity of the Veſſel.

The *Species* are;

1. Buxus *arboreſcens. C. B.* The Box-tree.

2. Buxus *arboreſcens, anguſtifolia.* The narrow-leav'd Box-tree.

3. Buxus *foliis ex luteo variegatis. H. R. Par.* Strip'd Box.

4. Buxus *major, foliis per limbum aureis. H. R. Par.* The Gold-edg'd Box-tree.

5. Buxus *humilis. Dod.* The Dwarf Box.

6. Buxus *humilis, foliis variegatis.* The Dwarf ſtriped Box.

7. Buxus *major, foliis per limbum argenteis.* The Silver-edg'd Box.

The firſt and ſecond Sorts grow in great Plenty upon *Box-hill* near *Darking* in *Surrey*, where were formerly large Trees of theſe Kinds; but of late they have been pretty much deſtroyed; yet there are great Numbers of the Trees remaining, which are of a conſiderable Bigneſs. The Wood of this Tree is very uſeful for Turners, Ingravers, and Mathematical Inſtrument-makers, the Wood being ſo hard, cloſe, and ponderous, as to ſink in Water, which renders it very valuable for divers Utenſils.

All the Varieties of the Tree, or large Box, are proper to intermix in Clumps of Ever-greens, &c. where they add to the Variety of ſuch Plantations. Theſe may be propagated by planting the Cuttings in *April* in a ſhady Border, obſerving to keep them water'd until they have taken Root, and may be afterward tranſplanted into Nurſeries, till they are fit for the Purpoſes intended. The beſt Seaſon for removing theſe Trees, is in *April* or *September*, tho' indeed, if Care be taken to take them up with a good Ball of Earth, they may be tranſplanted almoſt at any time, except in the Middle of Winter. Theſe Trees are a very great Ornament to cold and barren Soils, where few other Things will grow. They may alſo be propagated by laying down the Branches, or from Seeds.

The Dwarf Kind of *Box* is uſed for bordering of Flower-beds, or Borders; for which Purpoſe it far exceeds any other Plant, it being ſubject to no Injuries from Cold or Heat, and is of a long Duration, is very eaſily kept handſome, and, by the Firmneſs of its Rooting, keeps the Mould in the Borders from waſhing into the Gravel-Walks more effectually than any Plant whatever. This is increaſed by parting the Roots, or planting the Slips; but as it makes ſo great an Increaſe of itſelf, and ſo eaſily parts, it is hardly worth while to plant the Slips that have no Roots; but it is now become ſo common, that it may be purchaſed from the Nurſeries at a cheap Rate.

The Manner of planting this in Edgings, *&c.* is ſo well underſtood by every working Gardener, that it would be needleſs to mention any thing of that kind here.

C A

CAAPEBA.

This is an *American* Name for this Plant, and at preſent we have no *Engliſh* Name for it.

The *Characters* are;

It hath a Roſe-flower, conſiſting of four Leaves, which are placed orbicularly, but are ſterile; from the Middle ariſes the Pointal, which is plain, round, and umbilicated. The Embryo's grow at a ſeparate Diſtance on the ſame Plants, which afterward become ſoft ſpherical Berries, including rough Seeds.

The *Species* are;

1. CAAPEBA *folio orbiculari & umbilicato lævi. Plum. Nov. Gen.* Caapeba with a round umbilicated Leaf.
2. CAAPEBA *folio orbiculari umbilicato tomentoſo. Plum. Nov. Gen.* Caapeba with a round woolly umbilicated Leaf.
3. CAAPEBA *folio orbiculari non umbilicato. Plum. Nov. Gen.* Caapeba with a round Leaf, not umbilicated.

Theſe Plants are Natives of the warmeſt Parts of *America*, where they twiſt themſelves round whatever Trees or Shrubs grow near them, and ſometimes riſe to the Height of ſix or ſeven Feet. They are propagated by Seeds, which ſhould be ſown in Pots filled with freſh light Earth, early in the Spring. Theſe Pots muſt be plunged into a moderate Hot-bed of Tanners-bark, and muſt be frequently refreſhed with Water; when the Plants are come up about an Inch high, they ſhould be tranſplanted into ſmall Pots filled with light rich Earth, and plunged into the Hot-bed again, obſerving to water and ſhade them until they have taken new Root; after which time the Glaſſes ſhould be raiſed in warm Weather every Day, to admit freſh Air to the Plants, and they muſt be frequently refreſhed with Water. During the Summer Seaſon they may remain in the Hot-bed, but at *Michaelmas* they muſt be removed into the Bark-ſtove, where they ſhould have a moderate Degree of Heat, and muſt be frequently refreſhed with Water. The ſecond Year ſome of the ſtrongeſt Plants will flower, and will continue ſeveral Years after.

CABBAGE: *vide* Braſica.

CABINET, in a Garden, is a Conveniency which differs from an Arbour, in this; that an Arbour or Summer-houſe is of a great Length, and arch'd over Head in the Form of a Gallery; but a *Cabinet* is either ſquare, circular, or in Cants, making a kind of a Salon, to be ſet at the two Ends or in the Middle of a long Arbour.

CACALIANTHEMUM.

The *Characters* are;

It hath a floſculous Flower, conſiſting of many Florets, (like thoſe of Groundſel) but theſe Florets are cut into four Segments; whereas thoſe of Groundſel are divided into five Parts; the Cup of the Flower is alſo ſlenderer than that of the Groundſel.

The *Species* are;

1. CACALIANTHEMUM *folio nerii glauco. Hort. Elth.* Cacalianthemum, with a glaucous Oleander Leaf, *commonly call'd* the Cabbage-tree.
2. CACALIANTHEMUM *Africanum, Ficoidis folio. African* Cacalianthemum, with a Ficoides Leaf.

The firſt of theſe Plants was brought from the *Canary* Iſlands, and hath been ſeveral Years in the *Engliſh* Gardens, where it hath riſen to the Height of eight or ten Feet, and has often produced Flowers in the Autumn, which fall off without bringing any Seed. It hath been by ſome unſkilful Perſons called the *Cabbage-tree*, but for no other Reaſon than that the Stem of this Plant is ſoft, and has ſomewhat the Appearance of a Cabbage-ſtalk. By others it has been as improperly called the *Carnation-tree*, for no other Reaſon than that it has long, narrow, glaucous Leaves; from whence ſome Writers in Botany have called it *Arbor Lavendulæ folio*; *i. e.* a Tree with a Lavender Leaf, but as the Flower and Seeds do nearly agree with the *Cacalia*, ſo Dr. *Dillenius* has given it the Epithet of *Cacalianthemum*; to which I have taken the Liberty to add the ſecond Sort, as being of the ſame Genus, by Flower and Seeds, tho' it has been commonly known by the Epithet *Senecio*.

The firſt of theſe Plants may be propagated by Cuttings; which ſhould be taken off toward the latter End of *May*, and laid in a ſhady Part of the Green-houſe, for a Fortnight or three Weeks, that the Part where it was cut may be perfectly dry, and healed over, otherwiſe it is very ſubject to rot. Theſe Cuttings ſhould be planted in Pots filled with a ſandy Earth, mix'd with a little Lime Rubbiſh, and then plunged into a moderate Hot-bed; obſerving to ſhade them in the Heat of the Day, as alſo to admit the Air, by raiſing the Glaſſes; and every three or four Days they ſhould be refreſhed with Water; but you muſt not give them too much Water, leſt you rot them.

When the Cuttings are rooted, (which may be known by their putting forth new Leaves) they ſhould be enured to the open Air by degrees; into which they muſt be removed towards the End of *July*, or the Beginning of *Auguſt*, that they may be harden'd before Winter; but they muſt be placed in a well-ſhelter'd Situation, where they may be ſcreen'd from Winds, and ſhaded from the Mid-day Sun: In this Place they ſhould remain until the End of *September*, or Beginning of *October*; when they muſt be removed into the Green-houſe, and placed near the Windows, that they may enjoy the free Air, until the End of *October*; when the more hardy Plants are removed into the Houſe, and the whole Number of Plants are diſpoſed in the Order they are to remain during the Winter Seaſon: Therefore at this Time you muſt place theſe Plants in the Middle of the Houſe, where they may be beſt defended from Cold. During the Winter Seaſon, theſe Plants muſt be water'd but little; for much Wet at that Time is apt to rot them: but however, they muſt not be kept too dry; for then they will often ſhrink, which is equally deſtructive to them. In the Summer theſe Plants muſt be placed abroad in a well-ſhelter'd Situation, with *Sedums*, *Cotyledons*, and other ſucculent Plants; obſerving to refreſh them often with Water in dry Seaſons: and as the Plants advance, ſo they ſhould be removed into larger Pots; always obſerving to plant them in light ſandy Earth, mix'd with Lime Rubbiſh, in which they will thrive much better than in richer Earth.

The ſecond Sort is now very common in *England*, tho' it has not been near ſo long an Inhabitant of our Gardens as the former. This is a Native of the Country about the *Cape of Good Hope*; from whence it was brought to the Gardens in *Holland*, where it was firſt propagated in *Europe*, and hath been ſince communicated to moſt Parts of *Europe*. This Plant may be eaſily propagated by Cuttings, which may be taken from the old Plants any time during the Summer Seaſon. Theſe muſt be laid by to dry, as was directed for the former Sort, and may be managed in the like manner. This Plant may be treated in a hardier manner than the former, but muſt not have too much Wet in Winter. This flowers every Year with us, and will grow to be ſix or eight Feet high. The greateſt Beauty of this Plant conſiſts in its fine, glaucous, ſucculent Leaves, which, when broken, do emit a ſtrong Scent ſomewhat like Turpentine; from whence ſome Perſons have given it the Name of *Balm of Gilead Tree*, tho' very improperly.

CACALIA.

This Plant hath no *Engliſh* Name.

The *Characters* are;

It hath a floſculous Flower, conſiſting of many Petals, divided into four Parts, ſitting on the Embryo, and contained in an almoſt cylindrical Empalement. The Embryo afterward becomes a Seed, furniſhed with Down.

The *Species* are;

1. CACALIA *tomentoſa. C. B. P.* Woolly Cacalia.
2. CACALIA *foliis craſſis hirſutis. C. B. P.* Cacalia with thick hairy Leaves.
3. CACALIA *foliis cutaneis acutioribus, & glabris. C.B.P.* Cacalia, with ſmooth-pointed Leaves.
4. CACALIA *Pyrenaica, alliariæ folio. Tourn.* Pyrenean Cacalia, with an Alliaria Leaf.
5. CACALIA *Alpina foliis utrinque denſo & candidiſſimo tomento obſitis. Tourn.* Cacalia of the *Alps*, whoſe Leaves are covered on both Sides with a thick white Down.
6. CACALIA *Virginiana glabra, foliis deltoidibus ſinuatis ſubtus glaucis. Moriſ.* Smooth *Virginian* Cacalia, with ſinuated Leaves, which are of a Sea-green Colour on their Underſide.
7. CACALIA *foliis rotundioribus, ad caulem ſeſſilibus. Mor.* Cacalia, with round Leaves ſitting cloſe to the Stalk.

Theſe Plants do moſt of them grow wild on the mountanous Parts of *Auſtria*, the *Alps* and *Pyrenean* Mountains, from whence they have been obtained by ſome curious Botaniſts, who preſerve them in their Gardens for the Sake of Variety. The ſixth Sort was found in *Virginia*, from whence it was brought to *Europe*.

They are all of them very hardy Plants in reſpect to Cold, therefore they muſt have a cool ſhady Situation, and ſhould be planted in a ſtrong freſh Earth, which has not been dunged. They may be propagated by parting of their Roots in Autumn; and require no other Culture but to keep them clear from Weeds, and in very dry Weather to water them two or three times a Week.

They may alſo be propagated by Seeds, but theſe ſhould be ſown as ſoon as poſſible after they are ripe, for they will not grow, if they are kept long out of the Ground. Theſe Seeds ſhould be ſown in Pots filled with freſh loamy Earth, and placed in a ſhady Situation. In the Spring the Plants will appear, when they muſt be carefully weeded, and in dry Weather ſhould be frequently refreſhed with Water, which will greatly forward the Plants in their Growth. In Autumn they muſt be tranſplanted into a ſhady Border, at about a Foot apart, where they may remain to flower.

CACAO; The Chocolate-nut.

The *Characters* are;

It hath a Roſe-flower, conſiſting of a great Number of Petals, from whoſe many leav'd Empalement ariſes the Pointal, which is a Tube cut into many Parts, which afterward becomes a Fruit ſhaped ſomewhat like a Cucumber, and deeply furrowed, in which are contained ſeveral Seeds, collected into an oblong Heap, and are ſlit down ſomewhat like Almonds.

We have but one *Species* of this Plant, which is,

CACAO. *Cluſ. Exot.* The Chocolate-nut Tree.

This Tree is a Native of *America*, and is found in great Plenty in ſeveral Places between the Tropicks, but particularly at *Carraca* and *Carthagena*, on the River *Amazons*, in the Iſthmus of *Darien*, at *Honduras*, *Guatimala*, and *Nicaragua*. At all theſe Places it grows wild without Culture, but it is cultivated in many of the Iſlands which are poſſeſſed by the *French* and *Spaniards*, and was formerly planted in ſome of the Iſlands which are in the Poſſeſſion of the *Engliſh*; but it has been neglected for many Years paſt, ſo that at preſent it is ſo ſcarce in thoſe Places that the *Engliſh* are ſupplied with it by the *French* and *Spaniards*, who make the Inhabitants pay them a good Price for it; and as there is a great Quantity of it conſumed by the *Engliſh*, ſo conſequently it muſt make an Alteration in the Balance of Trade, greatly to the Prejudice of the *Engliſh*, which might be eaſily remedied if the Planters in our Colonies were but the leaſt induſtrious, ſince as it formerly did grow on thoſe Iſlands, ſo as to produce not only a ſufficient Quantity for their own Conſumption, but did ſupply *England* with great Quantities, ſo there can be no Objection to the planting of it in thoſe Iſlands again, eſpecially, ſince Sugars are become ſo bad a Commodity, that the Planters are moſt of them greatly reduced, and unleſs they can improve their Eſtates by ſome other Commodity, muſt be ruined in a few Years.

I ſhall therefore ſubjoin the beſt Account of this Plant, with the Culture which it requires in thoſe Countries, with the Profits which ariſe from it, to thoſe who have planted ſome of theſe Trees of late Years, by way of Experiment; and ſhall afterwards give Directions for the cultivating of it in *England*, by way of Curioſity.

In the making of a Plantation of Chocolate-Trees you muſt firſt be very careful in the Choice of the Situation and the Soil, otherwiſe there will be ſmall Hopes of Succeſs. As to the Situation, it ſhould be in a Place where the Trees may be protected from ſtrong Winds, to which if they are expoſed, they will ſoon be deſtroyed. So that in ſuch Places where Torrents of Water have waſhed away the Earth, ſo as to leave broad and deep Furrows, (which the Inhabitants of thoſe Iſlands call *Gullies*) theſe Trees will thrive exceedingly. And as theſe are very frequently to be found in thoſe Iſlands, and many of them being of large Extent, ſo it may be a great Improvement to ſome Eſtates, which at preſent are of ſmall Value. The Soil in theſe *Gullies* is generally rich and moiſt, which is what theſe Trees require, ſo that they will make great Progreſs in theſe Places, as hath been experienced by ſome few Perſons who have lately cultivated ſome of theſe Plants. But where there are not a ſufficient Number of theſe *Gullies*, Choice ſhould be made of a Situation which is well ſheltered by large Trees, or if there are not Trees already grown, there ſhould be three or four Rows planted round the Spot which is deſigned for the Chocolate-Trees; of ſuch Sorts which are of quickeſt Growth; and within theſe Rows there ſhould be ſome Plantain-Trees, planted at proper Diſtances, which being very quick of Growth, and the Leaves being very large, will afford a kindly ſhelter to the young Chocolate-Trees, which are placed between them.

The Chocolate-Trees which are cultivated ſeldom grow to be more than fourteen or fifteen Feet in Height, nor do they ſpread their Branches very wide, ſo that if the Plantain-Trees are placed in Rows about twenty-four Feet aſunder, there will be Room enough for two Rows of Chocolate-Trees between each Row of Plantains; and if they are planted at ten Feet Diſtance in the Rows it will be ſufficient Room for them. Thoſe Trees which are found wild in uncultivated Places, are generally of much larger Growth, which may be occaſioned by the other Trees, amongſt which theſe are found growing; for being protected from the Winds by thoſe, they are not ſo much in Danger therefrom, as thoſe which are cultivated; and the other Trees cloſely ſurrounding of them, will naturally draw them up to a greater Height. However, that is not a deſireable Quality in theſe Trees, for the lower they are the better the Fruit may be gathered without injuring of the Trees, and the leſs they are expoſed to the Injuries of the Weather. So that the Inhabitants never deſire to have their Trees above twelve or fourteen Feet high.

The Soil which theſe Trees thrive to moſt Advantage upon, is a moiſt, rich, deep Earth, for they generally ſend forth one tap Root, which runs very deep into the Ground, ſo that where-ever they meet with a rocky Bottom near the Surface, they ſeldom thrive, nor are they of long Continuance; but in a rich deep moiſt Soil they will produce Fruit in pretty good Plenty the third Year from Seed, and will continue fruitful for ſeveral Years.

Before the Plantation is begun, the Ground ſhould be well prepared by digging of it deep, and clearing it from the Roots of Trees and noxious Plants, which if ſuffered to remain in the Ground, would ſhoot up again after the firſt Rain, and greatly obſtruct the Growth of the Plants, and it will be almoſt impoſſible to clear the Ground from thoſe Roots, after the Chocolate-Plants are come up, without greatly injuring them.

When the Ground is thus prepared, the Rows ſhould be marked out by a Line, where the Nuts are to be planted, ſo as that they may be placed in a quincunx Order, at equal Diſtance every way, or at leaſt that the Plantain-Trees between them, may form a Quincunx, with the two Rows of Chocolate-Trees, which are placed between each Row of them.

In making a Plantation of Chocolate-nut-Trees, the Nuts muſt be planted where the Trees are to remain, for if the Plants are tranſplanted, they ſeldom live, and thoſe which may ſurvive it, will never make thriving Trees; for as I before obſerved, theſe Trees have a tender tap Root, which if broken, or any way injured, the Tree commonly decays.

The Nuts ſhould always be planted in a rainy Seaſon, or at leaſt when it is cloudy Weather, and ſome Hopes of Rain falling ſoon after. As the Fruit ripens at two different Seaſons, *viz.* at *Midſummer*, and at *Chriſtmas*, ſo the Plantation may be made at either of thoſe; but the chief Care muſt be to chooſe ſuch Nuts as are perfectly ripe and ſound, otherwiſe the whole Trouble and Expence will be loſt. The Manner of planting the Nuts is, to make three Holes in the Ground, within two or three Inches of each other, at the Place where every Tree is to ſtand; and into each of theſe Holes ſhould be one ſound Nut planted about two Inches deep, covering of them gently with Earth. The Reaſon for putting in three Nuts at every Place is, becauſe they ſeldom all ſucceed, or if moſt of them grow, the Plants will not be all equally vigorous; ſo that when the Plants have had one Year's Growth, it is very eaſy to draw up all the weak unpromiſing Plants, and leave thoſe which are the moſt vigorous; but in doing of this, great Care ſhould be had to the Plants which are to remain, ſo as not to injure or diſturb their Roots in drawing the other out.

It is very proper to obſerve, that the Chocolate-Nuts will not retain their growing Faculty long after they are taken from the Trees, ſo that there is no poſſibility of tranſporting them to any great Diſtance for planting; nor ſhould they be kept long out of the Ground, in the natural Places of their Growth. There are ſome Authors who have wrote the Hiſtory of this Tree, and diſtinguiſh three different Sorts of the Nuts, from the Colour of their Skins, one of which is of a whitiſh green Colour, one of a deep red, and the third of a red and yellow Colour; but theſe are not ſpecifically different, but do all ariſe from Seeds of the ſame Tree, as is the Caſe of our Filberts, which differ in the Colour of their Skins, but are of the ſame Colour within, and have the ſame Taſte. There are others, who would diſtinguiſh theſe Nuts by their Size and Form, ſome being large and thick, others almoſt as flat as Beans; but theſe Differences (I have been credibly informed) ariſe from ſome Accident, as thoſe Trees which are young and vigorous, and grow upon a rich deep Soil, will always produce larger and better nouriſhed Fruit than thoſe which ſtand on a ſhallow dry Ground, and are unthriving Trees. As will alſo the Age of a Tree make a great Alteration in the Size of the Fruit; for old Trees are generally obſerved to produce ſmaller and flatter Nuts than thoſe which are young, or than the ſame Trees did bear while they were vigorous.

When the Chocolate-Trees firſt appear above Ground, they are very tender, and ſubject to great Injuries from the ſtrong Winds, the ſcorching Sun, or great Droughts; for which Reaſon the Planters are obliged to guard againſt all theſe Enemies, firſt by making Choice of a ſheltered Situation, or at leaſt by planting Trees to form a Shelter; and, if poſſible, to have the Plantation near the River, for the Conveniency of watering the Plants the firſt Seaſon, until they have made ſtrong Roots, and are capable of drawing their Nouriſhment from ſome Depth in the Earth, where they meet with Moiſture. But in order to ſhelter the Plants from the ſcorching Rays of the Sun, they generally plant two Rows of Caſſada between each Row of Chocolate-Trees, which will grow about ſeven or eight Feet high, ſo will ſcreen the young Plants from the Violence of the Sun, the firſt Seaſon; after which Time they will be in leſs Danger of Injury therefrom; and the following Seaſon, when the Caſſada is taken up for Uſe, the Ground ſhould be worked between the young Plants, being very careful not to injure their Roots by this Operation. This Method of planting the Caſſada between the young Chocolate-Trees, is of great Advantage to the Planter; for when the Roots of the Caſſada are taken up for Uſe, it will defray the Expence of keeping the Ground clean from Weeds, without which the young Plants would come to nothing. The Plantains alſo, which will be fit to cut in about twelve Months after planting, will defray the whole Expence of preparing the Ground, ſo that the Produce of the Chocolate-Trees, will be neat Profit; for as the Plantains produce Fruit and decay, ſo they will be ſucceeded by Suckers, which will produce Fruit in eight Months after, whereby there will be a continual Supply of Food for the Negroes, which will more than pay for keeping the Ground wrought, and clear from Weeds until the Chocolate-Trees begin to produce Fruit, which is generally the third Year after planting.

The Planters uſually plant the Plantain-Trees two or three Months before the Chocolate-Nuts are ripe, that they may be ſo large as to afford Shelter to the young Plants when they come up, and the Caſſada is always planted a Month or ſix Weeks before the Chocolate-Nuts, for the ſame Reaſon. Some People plant Potatoes, others Cucumbers and Melons, or Water-Melons, between the Rows of Chocolate-Plants, which, they ſay, will prevent the Weeds from riſing to injure the young Plants; for as theſe do all of them trail upon the Ground, ſo they occupy the whole Surface, and prevent the Weeds from growing; but where this is practiſed it ſhould be done with great Caution, leſt by being over-covetous you injure the young Chocolate-Nuts ſo much, as that they may never recover it. Therefore great Care ſhould be taken to reduce the Shoots of theſe Plants, whenever they approach the Chocolate-Trees, otherwiſe they will ſoon greatly injure, if not totally deſtroy them.

In about ſeven or eight Days after the Chocolate-Nuts are planted, the young Plants will begin to appear above Ground, when they ſhould be carefully looked over to ſee if any of them are attacked by Inſects, in which Caſe, if the Inſects are not timely deſtroyed, they will ſoon devour all the young Plants. Or if there ſhould be any Weeds produced near the Plants, they ſhould be carefully cut down with a Hough, in doing of which great Care ſhould be taken that the tender Shoot is not injured. About twenty Days after the Plants have appeared, they will be five or ſix Inches high, and have four or ſix Leaves, according to the Strength of the Plants. Theſe Leaves are always produced by Pairs, oppoſite to each other, as are alſo the Branches; ſo that they make very regular handſome Heads, if they are not injured by Winds. In ten or twelve Months they will be two Feet and an half high, and have fourteen or ſixteen Leaves; by this Time the Caſſada which was planted between the Rows of Chocolate-Plants, will have large Roots fit for Uſe, ſo ſhould be then taken up, and the Ground being then wrought over again, will greatly encourage the young Plants.

In two Years Time the Plants will have grown to the Height of three Feet and a half, or ſometimes four Feet, many of which will begin to flower; but the careful Planters always pull off all theſe Bloſſoms, for if they are permitted to remain to produce Fruit, they will ſo much weaken the Trees that they ſeldom recover their Strength again, ſo as to make vigorous Trees. When theſe Plants are two Years and a half old, they will produce Flowers again, ſome of which are often left to produce Fruit, but the more curious Planters pull off all theſe, and never leave any to produce Fruit until the third Year, when they leave but a few in proportion to the Strength of the Trees; by which Method their Trees always produce larger and better nouriſhed Fruit than thoſe which are ſuffered to bear a larger Quantity, and the Trees will continue much longer in Vigour. The fourth Year they ſuffer their Trees to bear a moderate Crop, but they generally pull off ſome of the Flowers from thoſe Trees which are weak, that they may recover Strength before they are too old.

From the Time when the Flowers fall off to the Maturity of the Fruit, is about four Months; it is eaſy to know when the Fruit is ripe by the Colour of the Pods, which become yellow on the Side next the Sun. In gathering of the Fruit they generally place a Negro to each Row of Trees, who, being furniſhed with a Baſket, goes from Tree to Tree, and cuts off all thoſe which are ripe, leaving the others for a longer Time to ripen. When the Baſket, is full, he carries the Fruit and lays it in a Heap at one End of the Plantation, where, after they have gathered the whole Plantation, they cut the Pods lengthwiſe, and take out all the Nuts, being careful to diveſt them of the Pulp which cloſely adheres to them; and then they carry them to the Houſe, where they lay them in large Caſks, or other Veſſels of Wood raiſed above Ground, and cover them with Leaves of the *Indian* Reed and Mats, upon which they lay ſome Boards, putting ſome Stones thereon to keep them down cloſe, in order to preſs the Nuts. In theſe Veſſels the Nuts are kept four or five Days, during which Time they muſt be ſtirred and turned every Morning, otherwiſe they will be in danger of periſhing from the great Fermentation they are uſually in. In this time they change from being white to a dark red or brown Colour. Without this Fermentation they ſay the Nuts will not keep, but will ſprout, if they are in a damp Place, or ſhrivel and dry too much, if they are expoſed to Heat.

After the Nuts have been thus fermented, they ſhould be taken out of the Veſſels, and ſpread on coarſe Cloths, where they may be expoſed to the Sun and Wind; but at Night, or in rainy Weather, they muſt be taken under Shelter, otherwiſe the Damp will ſpoil them. If the Weather proves fair, three Days Time will be long enough to dry them, provided they are carefully turned from Time to Time, that they may dry equally on every Side. When they are perfectly dry they may be put up in Boxes or Sacks, and preſerved in a dry Place, until they are ſhipp'd off, or otherwiſe diſpoſed of. The freſher theſe Nuts are, the more Oil is contained in them, ſo that the older they are the leſs they are eſteemed.

Theſe Trees do not produce their Fruit on the young Branches, or at their Extremities, as do moſt other Trees; but from the Trunk and the larger Branches come out the Buds for Flowers and Fruit. While the Trees are young they do not produce their Fruit in great Plenty, for before the Trees are eight Years old they reckon it a good Crop to have twenty-eight or thirty Pods on each Tree at one Gathering, eſpecially that at *Midſummer*, which is always a much worſe Crop than the *Chriſtmas* Seaſon, which is occaſioned by the much greater Drought of the Spring; for the Autumns being the rainy Seaſons, the Chocolate-Trees produce a much greater Quantity of Fruit. When the Trees are full grown and vigorous, they will ſometimes produce two Hundred, or two Hundred and forty Pods, at one Seaſon, which will make ten or twelve Pounds of Chocolate, when dried, ſo that it is a very profitable Commodity, and can be managed with very little Charge, when compar'd with Sugar. I have been credibly inform'd by a Perſon of great Worth and Integrity, who reſided ſome Years in *America*, that he has ſeen as much Chocolate gathered from one Tree in a Year, as hath been worth thirty Shillings Sterling on the Spot; ſo that as the Trouble of gathering and preparing for the Market being much leſs than for many other Commodities which are manufactured in the *Britiſh* Colonies, it is ſurprizing it ſhould be neglected, eſpecially as it is ſuch a great Part of Suſtenance to the better Sort of Inhabitants of thoſe Colonies, that they cannot live comfortably without it, and purchaſe it from the *French* and *Spaniards* at a conſiderable Price, which muſt greatly impoveriſh the Colonies in Time.

The Chocolate-Trees, if planted on a good Soil, and are properly taken Care of, will continue vigorous and fruitful twenty-five or thirty Years; ſo that the Charge of cultivating a Plantation of theſe Trees muſt be much leſs than that of Sugar, which muſt be annually planted; for altho' the Ground between the Rows of Plants will require to be often houghed and wrought, yet the firſt working of a Ground to make a new Plantation of Sugar, Indigo, Caſſada, *&c.* is a larger Expence than the after Workings are. Beſides, Sugar-canes require as much Labour in their Cultivation as any Plant whatever; and ſince the Inſects which deſtroy the Sugar-canes, have ſpread ſo much in the *Britiſh* Colonies, nothing is a more uncertain Crop than Sugar, for which Reaſon I think it would be greatly worth the Planters Care, who are poſſeſſed of proper Lands for the Chocolate-Trees, to make ſome ſmall Trials at leaſt to be convinced of the Truth of this Fact.

The Leaves of theſe Trees being large, make a great Litter upon the Ground when they fall; but this is not injurious, but rather of Service to the Trees; for the Surface of the Ground being covered with them, they preſerve the Moiſture on the Surface, which is of great Uſe to the young tender Roots which are juſt under the Surface; and when the Leaves are rotten, they may be buried in digging of the Ground, and it will ſerve as good Manure. Some Planters let the Pods in which the Chocolate is incloſed, lie and rot in a Heap; (after they have taken the Nuts out) which they alſo ſpread on the Ground inſtead of Dung. Either of theſe Manures are very good, provided they are well rotted before they are lay'd on the Ground; and great Care ſhould be had, that no Vermin ſhould be carried on the Plantation with the Dung.

Beſides the ordinary Care of digging, houghing, and manuring the Plantations of Chocolate-Trees, there is alſo another Thing requiſite in order to their doing well, which is, that of pruning the decayed Branches off, and to take off ſmall ill-placed Branches, where-ever they are produced. But you ſhould be cautious how this Work is performed, for there ſhould be no vigorous Branches ſhortened, nor any large Amputations made on theſe Trees; for they abound with a ſoft glutinous milky Juice, which will flow out for many Days whenever they are wounded, which greatly weakens the Trees. However, ſuch Branches whoſe extreme Parts are decayed, ſhould be cut off, to prevent the Infection from going farther on; and ſuch Branches as are much decayed, ſhould be taken off cloſe to the Stem of the Tree; but this Operation ſhould be performed in dry Weather, ſoon after the Crop of Fruit is gathered.

Some People perhaps may imagine, that what I have directed is a tedious laborious Work, and not to be performed by a few Slaves, but this is a great Miſtake; for I have been credibly inform'd, that five or ſix Negroes will cultivate a Plantation of ten Thouſand of theſe Trees, provided they are properly inſtructed, which is a ſmall Number, when compared to the Quantity neceſſary to cultivate a Sugar Plantation of the like Extent of Ground. And when the Profits of both are compared, there will be a great Difference; for ſuppoſing we ſet the Price of five Shillings, for the Produce of each Tree, when grown, *per Annum*, (which I think is being very moderate, conſidering what has been related) then a Plantation of ten Thouſand Trees will produce twenty-five Hundred Pounds a Year, which to be managed by ſix or ſeven Negroes, without the Expence of Furnaces, *&c.* is a much greater Profit than I believe can be made from any other Commodity.

In order to cultivate this Plant in *Europe*, by way of Curioſity, it will be neceſſary to have the Nuts planted into Boxes of Earth (in the Countries where they grow) ſoon after they are ripe (becauſe if the Nuts are ſent over they will looſe their growing Quality before they arrive.) Theſe Boxes ſhould be placed in a ſhady Situation, and muſt be frequently watered, in order to forward the Vegetation of the Nuts. In about a Fortnight after the Nuts are planted, the Plants will begin to appear above Ground; when they ſhould be carefully watered in dry Weather, and protected from the violent Heat of the Sun, which is very injurious to theſe Plants, eſpecially while they are young; they ſhould alſo be kept very clear from Weeds, which if ſuffered to grow in the Boxes will ſoon overbear the Plants, and deſtroy them: When the Plants are grown ſtrong enough to tranſport, they ſhould be ſhipped, and placed where they may be ſcreen'd from ſtrong Winds, ſalt Water, and the violent Heat of the Sun. During their Paſſage they muſt be frequently refreſh'd with Water, but it muſt not be given to them in great Quantities, leſt it rot the tender Fibres of their Roots, which will deſtroy the Plants; and when they come into a cool Latitude, they muſt be carefully protected from the Cold, when they will not require ſo frequently to be watered; for in a moderate Degree of Heat, if they have gentle Waterings twice a Week, it will be ſufficient.

When the Plants arrive in *England*, they ſhould be carefully taken out of the Boxes, and each tranſplanted into a ſeparate Pot filled with light rich Earth, and plunged into a moderate Hot-bed of Tanners-bark, being careful to cover the Glaſſes in the Heat of the Day, to ſcreen the Plants from the Sun; they muſt alſo be frequently watered, but it muſt be done with Caution, not to rot their Roots; in this Hot-bed the Plants may remain till *Michaelmas*, when they muſt be remov'd into the Bark-ſtove, and plunged into the Tan, in the warmeſt Part of the Stove. During the Winter Seaſon the Plants muſt be frequently refreſhed with Water, but it muſt be given to them in ſmall Quantities, but in Summer they will require a more plentiful Share. Theſe Plants are too tender to live in the open Air in this Country, even in the hotteſt Seaſon of the Year, ſo they muſt conſtantly remain in the Bark-ſtove, obſerving in very warm Weather to let in a large Share of freſh Air to them, and in Winter to keep them very warm: As the Plants increaſe in Bulk, ſo they ſhould be ſhifted into larger Pots, in doing of which there muſt be particular Care taken not to tear or bruiſe their Roots, which often kills the Plants, nor muſt they be placed in Pots too large, becauſe that is a ſlow but ſure Death to them: The Leaves of theſe Plants muſt be frequently waſhed, to clear them from Filth, which they are ſubject to contract by remaining conſtantly in the Houſe, and this becomes a Harbour for ſmall Inſects, which will infeſt the Plants, and deſtroy them, if they are not timely waſhed off: If theſe Rules are duly obſerved, the Plant will thrive very well, and may produce Flowers in this Climate, but it will be very difficult to obtain Fruit from them; for, being of a very tender nature, they are ſubject to many Accidents in a cold Country.

CACHRYS.

We have no *Engliſh* Name for this Plant.

The *Characters* are;

The Flowers grow on an Umbel, which conſiſt of many Petals ranged circularly, and expand in Form of a Roſe, theſe reſt on the Empalement, which turns to a Fruit, compoſed of two Parts, which are half oval, ſometimes ſmooth, and ſometimes rough and channelled, containing Seeds which reſemble Barley-corns.

The *Species* are;

1. CACHRYS *ſemine fungoſo ſulcato aſpero, foliis ferulaceis. Mor. Umb.* Cachrys, with a fungous, furrowed, rough Seed, and Fennel-giant Leaves.
2. CACHRYS *ſemine fungoſo ſulcato aſpero, foliis peucedani latiuſculis. Mor. Umb.* Cachrys, with a fungous, furrowed, rough Seed, and broadiſh Hogs-fennel Leaves.
3. CACHRYS *ſemine fungoſo ſulcato plano majore, foliis peucedani anguſtis. Mor. Hiſt.* Cachrys, with larger plain furrow'd fungous Seed, and narrow Hogs-fennel Leaves.
4. CACHRYS *ſemine fungoſo ſulcato plano minore, foliis peucedani. Mor. Umb.* Cachrys, with ſmaller plain furrow'd fungous Seed, and Hogs-fennel Leaves.
5. CACHRYS *Hungarica, panacis folio. Tourn.* Hungarian Cachrys, with an All-heal Leaf.
6. CACHRYS *foliis pucedani, ſemine fungoſo ſulcato aſpero minori. Tourn.* Cachrys, with Hogs-fennel Leaves, and ſmall rough fungous Seed.
7. CACHRYS *Cretica, angelicæ folio, aſphodeli radice. Tourn.* Candy Cachrys, with an Angelica Leaf, and an Aſphodel Root.
8. CACHRYS *Orientalis, ferulæ folio, fructu alato plano. Tourn. Cor. Eaſtern* Cachrys, with a Fennel-giant Leaf, and a plain winged Seed.

Theſe Plants are all propagated by Seeds, which ſhould be ſown ſoon after they are ripe, for if they are kept out of the Ground until the following Spring, they often miſcarry, and when they ſucceed, they never come up until the Spring after, ſo that by ſowing them in *Autumn* a whole Year is ſaved, and the Seeds ſeldom miſcarry. Theſe Seeds ſhould be ſown on a ſhady Border, where the Plants are to remain, for the Plants having long Tap Roots do not bear tranſplanting ſo well as many other Kinds: The Diſtance to be obſerv'd for the ſowing of their Seeds ſhould be two Feet apart; ſo if each kind is ſown in a Drill, when the Plants are come up, they may be thinned, leaving two or three of the moſt promiſing Plants of each kind to remain: Theſe Plants will begin to appear early in *April*, when they muſt be carefully clear'd from Weeds, and in dry Weather they ſhould be watered gently, which will greatly promote their Growth the firſt Year; after which time they will require no farther Care but to keep them clean from Weeds, and every Spring to dig the Ground carefully between them.

Theſe Plants decay to the Ground every *Autumn*, and come up again in the Spring; they commonly flower in the Beginning of *May*, and their Seeds are ripe in *Auguſt*; their Roots ſometimes run down three or four Feet deep in the Earth, provided the Soil be light, and are often as large as Parſnips: They will continue many Years, and if the Soil is moiſt and rich, they will annually produce good Seeds, but when they grow on a dry Soil, the Flowers commonly fall away, and are not ſucceeded by Seeds.

There is but little to be ſaid of the Uſes of This Genus of Plants: The *Hungarians* in the Neighbourhood of *Erlaw*, as alſo thoſe who border on *Tranſylvania*, *Servia*, &c. eat the

Root of the Fifth Species in a Scarcity of Corn, for Want of other Bread.

CÆSALPINA.

This Plant was ſo named by Father Plumier, *who diſcover'd it in* America, *in Honour to* Andreas Cæſalpinus, *who was an eminent Botaniſt, and one of the firſt Writers on a Method of claſſing Plants.*

We have no *Engliſh* Name for this Plant.

The *Characters* are;

It hath a Flower of an anomalous Figure, conſiſting of one Leaf, which is divided into four unequal Parts; the upper Part is large and hollowed like a Spoon. From the Bottom of the Flower ariſes the Pointal, amongſt many incurved Stamina, which afterward becomes a Pod, including oblong Seeds.

We have but one Sort of this Plant, *viz.*

CÆSALPINA *polyphylla, aculeis horrida. Plum. Nov. Gen.* Many-leav'd Cæſalpina, with large Thorns.

This Plant is a Native of *America*, where it riſes to the Height of fourteen or ſixteen Feet, the Trunk and Branches being arm'd with very ſtrong Thorns, ſo that it is difficult to paſs where they are in Plenty. It was found at *Campechy* by the late Doctor *Houſtoun*, who ſent the Seeds into *England*, from which ſome of theſe Plants were raiſed.

This Plant is propagated by Seeds, which ſhould be ſown in ſmall Pots filled with light rich Earth early in the Spring, and plunged into a Hot-bed of Tanners-bark, obſerving to water the Earth as often as it appears dry, in order to promote the Vegetation of the Seeds; and if the Nights ſhould prove cold, the Glaſſes of the Hot-bed ſhould be cover'd with Mats, to keep the Bed in a moderate Warmth: In about two Months after the Plants will begin to appear, when they muſt be carefully clear'd from Weeds, and frequently refreſh'd with Water, and in warm Weather the Glaſſes of the Hot-bed ſhould be raiſed in the middle of the Day, to admit freſh Air to the Plants, which will greatly ſtrengthen them: When the Plants are about three Inches high, they ſhould be carefully taken out of the Pots, and each tranſplanted into a ſeparate ſmall Pot filled with light freſh Earth, and plunged into the Hot-bed again, obſerving to water them, and ſcreen them from the Heat of the Sun, until they have taken new Root, after which time the Glaſſes of the Hot-bed ſhould be raiſed every Day, in proportion to the Heat of the Weather, to admit freſh Air to the Plants, and they muſt be duly watered, and kept clear from Weeds; in this Hot-bed the Plants may remain until they touch the Glaſſes with their Tops, when they will be in Danger of being ſcorch'd by the Sun, which will retard their Growth; therefore whenever they are grown ſo tall as to touch the Glaſſes with their Tops, they ſhould be removed into the Stove, and plunged into the Bark-bed, where they may have Room to grow. Theſe Plants being tender, ſhould always be kept in the Bark-ſtove, and have a moderate Share of Heat in Winter, and being plac'd amongſt other tender Exotick Plants of the ſame Country, will afford an agreeable Variety.

CAINITO, [This is the *American* Name, by which the *Indians* called this Tree, according to *Oviedo*] Star-Apple, *vulgo*.

The *Characters* are;

It hath an open Bell-ſhap'd Flower, conſiſting of one Leaf, and cut into ſeveral Segments towards the Top; from whoſe Cup ariſes the Pointal, which afterward becomes a globular or olive-ſhap'd ſoft, fleſhy Fruit, incloſing a Stone of the ſame Shape.

The *Species* are;

1. CAINITO *folio ſubtus aureo, fructu maliformi. Plum. Nov. Gen.* The Star-Apple, *vulgo*.
2. CAINITO *folio ſubtus aureo, fructu olivæformi. Plum. Nov. Gen.* Cainito with olive-ſhap'd Fruit.

Theſe Plants grow in the warmeſt Parts of *America*, where the Fruit of the firſt Sort is eaten by way of Deſert: This Tree grows to the Height of thirty or forty Feet, and has a ſtreight ſmooth Stem, regularly beſet with Branches, which are adorn'd with Leaves of a ſhining green Colour on their upper Sides, but of a ruſſet colour underneath; from the ſetting on of the Footſtalks of the Leaves comes out the Flowers, which have no great Beauty, but are ſucceeded by the Fruit, which is about the Size of a large Apple, and of the ſame Shape.

The other Sort is not ſo common in our Settlements in *America*, but grows very plentifully in the *Spaniſh Weſt-Indies*, from whence I have receiv'd Seeds of this and the former kind.

They are both propagated by Seeds, which ſhould be ſown in Pots filled with light freſh Earth, and plunged into a Hot-bed of Tanners-bark, obſerving to refreſh the Earth often with Water, in order to promote the Vegetation of the Seeds: When the Plants are come up three Inches high, they ſhould be ſhaken out of the Pots, and carefully parted; then put each into a ſeparate ſmall Pot filled with freſh Earth, and plunge them into the Hot-bed again, being careful to ſhade the Glaſſes until the Plants have taken new Root, after which time they ſhould have Air and Water in proportion to the Warmth of the Seaſon; when the Plants have grown ſo much as that their Roots are confin'd by theſe Pots, they ſhould be ſhifted into larger, always obſerving to preſerve a Ball of Earth to their Roots.

Theſe Plants will not bear the cold of our Air in Summer, ſo muſt always be preſerv'd in the Bark-ſtove, and treated after the manner directed for the Coffee-tree; with this Management the Plants will thrive exceedingly, and it is hoped, will ſoon produce Flowers in *England*.

CAKILE, Sea-Rocket.

The *Characters* are;

It hath a croſs-ſhap'd Flower, conſiſting of four Petals, from whoſe Cup ariſes the Pointal, which afterward becomes a Fruit, reſembling the Point of a Spear, and is jointed, in each of which Diviſions is lodged one Seed, which is for the moſt part oblong.

The *Species* are;

1. CAKILE *maritima, ampliore folio. T. Cor.* Sea-Rocket, with a larger Leaf.
2. CAKILE *maritima, anguſtiore folio. T. Cor.* Sea-Rocket, with a narrow Leaf.
3. CAKILE *Græca arvenſis, ſiliqua ſtriata brevi. T. Cor.* *Greek* Sea-Rocket, with a ſhort ſtriated Pod.
4. CAKILE *Orientalis, fructu minimo verrucoſo. T. Cor.* *Eaſtern* Sea-Rocket, with a ſmall warted Fruit.

The two firſt Sorts grow wild in divers Parts of *Europe* on the Sea-ſhore, where the Salt Water generally flows: The ſecond Sort is pretty common in *England*, but the firſt hath not been found wild in this Country: The third and fourth Sorts were diſcovered by Doctor *Tournefort*, who ſent their Seeds to the royal Garden at *Paris*.

They are all annual Plants, their Seeds ſhould be ſown in *Autumn*, ſoon after they are ripe, in the Place where they ſhould remain, for they will not bear tranſplanting well; when the Plants are come up, they ſhould be kept clear from Weeds, and where they are too cloſe, they muſt be thinned, ſo as to leave them four or five Inches aſunder, which is all the Culture they require; in *June* they will flower, and their Seeds will ripen in *Auguſt*; there is no Beauty or Uſe in theſe Plants at preſent known, but they are preſerved in botanick Gardens for Variety.

CALABA, *Indian* Maſtick-tree.

The *Characters* are;

It hath a roſaceous Flower, conſiſting of ſeveral Petals, which are placed in a circular Order, from whoſe Flower-cup riſes the Pointal, which afterwards becomes a ſpherical fleſhy Fruit, including a Nut of the ſame Form.

We know but one Sort of this Plant, which is,

CALABA *folio citrii ſplendente. Plum. N. G.* 39. *Indian* Maſtick-tree, with a ſhining Citron Leaf.

This Tree grows to a great Magnitude in the warm Parts of *America*, where it is a Native: From the Trunk and Branches there iſſues out a clear Gum, ſomewhat like Maſtick, from whence it received its Name, the Gum being us'd in thoſe Countries as Maſtick.

At preſent this Tree is pretty rare in *England*, it being ſo tender as not to bear the open Air; ſo that it muſt be preſerv'd in Stoves, with the moſt tender Exotick Plants; it is propagated by the Nuts, which are frequently brought from *America*; theſe ſhould be planted in ſmall Pots filled with freſh light Earth, and plunged into a Hot-bed of Tanners-bark, obſerving to water the Pots frequently, to forward the Vegetation of the Nuts, which having hard Shells, are pretty long before they break their Covers, unleſs they have a good Share of Heat and Moiſture. When the Plants are come up about two Inches high, they ſhould be carefully tranſplanted, each into a ſeparate ſmall Pot filled with light freſh Earth, and plung'd into a moderate Hot-bed of Tanners-bark, obſerving to water and ſhade them until they have taken new Root, after which time they ſhould have Air admitted to them in proportion to the Heat of the Weather and the Bed in which they are placed, and they muſt be frequently watered in warm Weather; in this Bed they may remain during the Summer Seaſon, but at *Michaelmas* they ſhould be remov'd into the Bark-ſtove, and plac'd in a warm Situation; during the Winter Seaſon theſe Plants will require Water pretty often, but it ſhould not be given to them in large Quantities, eſpecially in cold Weather, leſt it rot the Fibres of their Roots.

The Spring following the Plants ſhould be ſhaken out of the ſmall Pots, in which they were placed, and tranſplanted into Pots of a larger Size, obſerving to pare off all the decay'd Fibres, and fill the Pots with the above-mention'd freſh Earth, and plunge them into the Hot-bed again, obſerving to water them more frequently, and give them a greater Share, as the Weather increaſes warm: The other Management of theſe Plants being the ſame as hath been directed for the *Coffee-tree* and ſome other tender Exotick Trees, it need not be repeated.

CALAMINTHA, [Καλαμίνθα, of καλὴ, fair or beautiful, and μινθὴ, Mint, becauſe the Virtues are like that of *Mint*.] Calamint.

The *Characters* are;

It hath a long tubulous Flower, which opens at the Top into two Lips; the upper Lip or Creſt is roundiſh, and divided into two Segments; the lower Lip or Beard is divided into three; theſe Flowers are produced from the Joints of the Stalks at the Foot-ſtalks of the Leaves, in Bunches, upon pretty long Pedicles or Footſtalks.

The *Species* are;

1. Calamintha *vulgaris, vel officinarum Germaniæ. C.B.* The common Calamint.
2. Calamintha *pulgei odore, foliis latioribus. H. L.* Broad-leav'd Calamint, with a Penyroyal Smell.
3. Calamintha *magno flore. C. B.* Calamint with large Flowers.
4. Calamintha *incana, ocymi foliis. C. B.* Hoary Calamint, with Leaves like Baſil.

The firſt of theſe Sorts is found wild in many Parts of *England*, but may be propagated in Gardens, by ſowing the Seeds in Spring, or parting the Roots: it will grow in almoſt any Soil or Situation. This is the Sort commonly uſed in Medicine; tho' the ſecond Sort hath of late prevailed in the Markets. The ſecond and third Sorts may be propagated in the ſame Manner as the firſt, and are equally as hardy. The fourth Sort is ſomewhat tenderer, and ſhould be kept in Pots, and ſhelter'd in Winter: This is increaſed by planting Cuttings in any of the Summer Months.

CALCEOLUS, Ladies Slipper.

The *Characters* are;

It hath an anomalous Flower, conſiſting of ſix diſſimilar Leaves, four of which are placed in the Form of a Croſs; the other two poſſeſs the Middle, one of which is bifid, and reſts upon the other, which is ſwelling, and ſhaped like a Shoe: The Empalement becomes a Fruit, open on three Sides, to which adhere the Valves, pregnant with very ſmall Seeds like Duſt.

The *Species* are;

1. Calceolus *Marianus. Dod.* Ladies Slipper.
2. Calceolus *flore majore. Tourn.* Ladies Slipper, with a larger Flower.
3. Calceolus *Marianus Canadenſis. Cornut.* Canady Ladies Slipper.
4. Calceolus *Mariæ luteus. Mor. H. R. B.* The yellow Ladies Slipper.

The firſt Species grows wild in the North of *England*, and in *Scotland*; from whence the Plants may be procured. The beſt Seaſon for tranſplanting of them is in *Autumn*, juſt as the Leaves decay; when the Roots ſhould be carefully taken up with a large Ball of Earth to them, and muſt be planted in a ſtrong loamy Soil, and in a ſhady Situation; where if they are ſuffered to remain undiſturbed, they will produce their beautiful Flowers in *May*, and may be preſerved ſeveral Years: But if they are placed in a warm, rich Soil, they will not thrive, and rarely produce any Flowers.

The ſecond Sort is not a Native of *England*, but is equally hardy with ours; ſo that if Roots can be procured from abroad, they muſt be treated in the ſame Manner as hath been directed for that.

The third Sort is found in *New-England*, *Virginia*, and *North-Carolina*, in moiſt Woods, from whence the Roots may be procured. Theſe muſt have a moiſt, ſhady Situation, and in Winter ſhould be ſcreened from ſevere Froſts, otherwiſe they cannot be preſerv'd in this Country: For although they are found wild in Countries where they have much colder Winters, yet growing in the Woods, they are covered with Leaves, and are protected by the Trees; ſo that the Froſt doth not penetrate very deep into the Earth.

All theſe Plants ſhould be placed in a ſhady Situation, and in dry Weather muſt be frequently water'd, otherwiſe they will not thrive, for they generally grow on moiſt ſpringy Soils, and where they are ſhaded with Trees; ſo that where there is not particular Care to keep them moiſt during their Seaſon of Growth, they ſeldom thrive in Gardens.

CALF's-SNOUT. *Vide* Antirrhinum.

CALTHA, Marygold.

The *Characters* are;

It hath a radiated diſcous Flower; the Petals of the Flower are, for the moſt part, crenated; the Seeds are crooked and rough; thoſe which are outermoſt are long, and thoſe within are ſhort: the Leaves are long, intire, and ſucculent.

The *Species* are;

1. Caltha *vulgaris, flore citrino. C. B.* The common Marygold.
2. Caltha *vulgaris, flore pallido. C. B.* The pale-colour'd Marygold.
3. Caltha *polyanthos major. C. B.* The large double Marygold.
4. Caltha *polyanthos maxima. C. B.* The largeſt double Marygold.
5. Caltha *minima. J. B.* The ſmalleſt Marygold.
6. Caltha *media, folio longo, prolifera. Boerh. Ind.* The childing Marygold.
7. Caltha *Africana, flore intus albo, extus violaceo. Tourn.* The *African* Marygold with Flowers that are white within, and of a violet Colour on the Outſide.
8. Caltha *Africana, flore intus albo, extus leviter violaceo, ſemine plano cordato. Boerh. Ind.* *African* Marygold, with Flowers white within, and of a ſoft violet Colour without, and flat Heart-ſhap'd Seeds.
9. Caltha *Africana, foliis croci anguſtis, florum petalis externe purpuraſcentibus, interne albis. Boerh. Ind.* *African* Marygold, with narrow Leaves like Saffron, and the Petals of the Flower white within, and purple without.

The ſix Sorts firſt mention'd are very hardy Plants, and may be ſown in Beds or Borders of common Earth in any Part of the Garden. They are all Annuals; yet if their Seeds are ſuffer'd to fall to the Ground, they will ſupply you, without the Trouble of ſowing them. But in order to keep the Sorts diſtinct, we ſhould carefully ſave the Seeds of each, and ſow them in the Spring, eſpecially the largeſt, double, and childing Kinds, which are often kept in Gardens for the Beauty of their Flowers, the other are only ſow'd for Pot-herbs. The ſeventh and eighth Sorts are very pretty Annual Plants, and ſhould be ſowed in a warm Border, and in a light Soil, and may be, while young, tranſplanted into other Parts of the Garden, where they are to remain: but if they are grown large before you remove them, it is a great Hazard if they grow again. Theſe Plants will continue producing great Quantities of beautiful Flowers moſt part of the Summer; and if the Seaſon is not too cold and wet, will ripen their Seeds very well; which you muſt be careful to gather when ripe, for they ſoon fall to the Ground.

The ninth Sort is an abiding Plant, and never produces any good Seeds in this Country; but may be propagated by Cuttings, which ſhould be planted in Pots of good light Earth, and plung'd into a gentle Hot-bed, refreſhing them often with Water, and ſhading them from the great Heats of the Sun, until they have taken Root; when you muſt harden them by degrees, to endure the open Air. This Plant muſt be hous'd in Winter with the *Ficoides*, &c. but muſt have as much free open Air as poſſible when the Weather is mild; for if it is kept too cloſe, it is very ſubject to grow mouldy and rot away; it continues flowering the greateſt part of the Year, for which it is very valuable, and often produces its Flowers in the middle of Winter, when few other Flowers appear.

CALTHA PALUSTRIS. *Vide* Populago.

CALYX [with *Botaniſts*, ſignifies the Cup of a *Flower* before it opens, or the ſoft Huſk or Skin in which a *Flower* firſt of all, and afterwards the Seeds of Herbs and Fruit of Trees, is cover'd.] Lat. *The Cup incloſing or containing the Flower.*

CAMARA, *American* Viburnum, *vulgo.*

The *Characters* are;

It hath an anomalous perſonated Flower, conſiſting of one Leaf, whoſe upper Lip (or Creſt) is erect, but the Beard (or under Lip) is divided into three Parts. The Embryo upon which the Flower ſits, afterward becomes a ſoft Fruit or Berry, incloſing a hard, round Seed; to which may be added, that many Embryo's are collected into one Body.

The *Species* are;

1. **Camara** *ſpinoſa, flore variegato. Plum. Nov. Gen. American* Viburnum, with a variegated Flower.
2. **Camara** *trifolia, purpuraſcente flore. Plum. Nov. Gen. American* Viburnum, with three Leaves and a purpliſh Flower.
3. **Camara** *ſalviæ foliis, floribus incarnatis. American* Viburnum, with Sage Leaves, and fleſh-colour'd Flowers.
4. **Camara** *meliſſæ folio, flore variabili. Hort. Elth. American* Viburnum, with a Balm Leaf, and a variable Flower.

Theſe Plants are Natives of *America*, where there are ſeveral other Species than are here enumerated. They may be raiſed from Seeds, which may be obtain'd from *Jamaica, Barbadoes*, or any of the warm Iſlands in the *Weſt-Indies*; where they are known by the Name of *Wild Sage.* Theſe Seeds ſhould be ſown in *February* or *March*, in ſmall Pots filled with light rich Earth, which ſhould be plunged into a Hot-bed of Tanners-bark, obſerving to refreſh the Earth often with Water; and in the Heat of the Day the Glaſſes ſhould be raiſed to admit the Air to the Pots, otherwiſe the Bed will be ſo hot as to endanger the ſcalding of the Seeds. In about five or ſix Weeks after the Seeds are ſown, the Plants will begin to appear; when you muſt be careful to refreſh them often with Water, as alſo to give them Air, in proportion to the Warmth of the Bed in which they are placed; and ſo ſoon as the Plants are two Inches high, they ſhould be taken carefully out of the Pots in which they were ſown, and tranſplanted, each into a ſeparate ſmall Pot filled with freſh light Earth, and plunged again into the Hot-bed: But you muſt obſerve to ſtir up the Bark with a Dung-fork, that it may renew its Heat; and when the Pots are plunged, you muſt water them pretty well, to ſettle the Earth to the Plants, which muſt be repeated often: You muſt alſo ſhade the Glaſſes until the Plants have taken new Root; after which Time they ſhould have Air and Water, in proportion to the Heat of the Seaſon, and the Bed in which they are plac'd.

By the Middle or latter End of *June* the Plants will have acquired Strength, and the Roots will fill the ſmall Pots into which they were planted; therefore you ſhould ſhake them out of thoſe, and put them into Pots of a larger Size, which ſhould be again plunged into the Hot-bed, to encourage the Plants to take Root; after which Time they ſhould be enured by Degrees to the open Air, into which they ſhould be removed in the middle of *July*, placing them in a warm Situation, where they may be defended from ſtrong Winds; and toward the End of the Month they will begin to ſhew their Flowers, which are produc'd in Cluſters at the Extremity of the Branches, and will continue in Beauty for near three Months.

Toward the End of *September* theſe Plants muſt be removed into the Stove, obſerving to place them where they may enjoy free Air, and have the Benefit of the Sun, as alſo to refreſh them often with Water; but in the Depth of Winter you muſt not give them too much at one Time: You muſt alſo keep them clear from dead Leaves, or decayed Branches; which, if ſuffered to remain, are often injurious to the Plants.

Theſe Plants muſt remain in the Stove until *June*; for if they are carried abroad too ſoon, they are often injur'd by the cold Nights, which frequently happen in *May.* But you ſhould let them have as much Air as poſſible in the Spring, when the Weather is mild, otherwiſe the Shoots will be weak, and when the Plants are expoſed they generally decay, whereby their Flowers are deſtroyed. When they are removed out of the Stove, they ſhould be placed in a warm Situation, and muſt be frequently watered; which will cauſe them to produce much ſtronger Flowers, and in greater Plenty than otherwiſe they would. With this Management the Plants will grow to the Height of five or ſix Feet, and may be trained to have regular Heads, and in warm Seaſons will often produce ripe Seeds in *England.*

They may alſo be propagated from Cuttings, which ſhould be taken from the old Plants in *April*, and muſt be planted into Pots filled with light rich Earth, and plunged into a Hot-bed of Tanners-bark, obſerving to water and ſhade them until they have taken Root; after which Time they muſt be treated in the Manner directed for the ſeedling Plants.

CAMPANIFORM *Flowers*, [of *Campana* a Bell; and *Forma*, Lat. Shape.] Such *Flowers* as in Shape reſemble a Bell.

CAMPANULA [ſignifies a little Bell, as tho' *parva Campana*, Lat. ſo called, becauſe the Flowers reſemble a *little Bell.* It is alſo call'd *Trachelium*, of τραχύτης, *Roughneſs*; either becauſe it is a very rough Plant, or becauſe it is good for Inflammations of the *Tracheal Artery.* It is alſo call'd *Uvularia*, becauſe it is good againſt Diſeaſes of the *Uvula*; and alſo *Cervicaria*, of *Cervix* the Neck, becauſe it heals Diſeaſes of the Neck. It is likewiſe call'd *Pentagonia*, becauſe the Flowers contract themſelves into five Angles, eſpecially in the Evening.] Bell-Flower.

The *Characters* are;

The Flower conſiſts of one Leaf, is ſhap'd like a Bell, and is, before blown, of a pentagonal Figure; and, when fully open'd, is cut into five Segments at the Top. The Seed-veſſel is, for the moſt part, divided into three Cells, each having a Hole at the Bottom, by which the Seed is emitted.

The *Species* are;

1. **Campanula** *pyramidata altiſſima. Tourn.* The talleſt pyramidal Bell-flower.
2. **Campanula** *perſicæfolia Lobelii, flore cœruleo. Mor. Hiſt.* The blue Peach-leav'd Bell-flower.
3. **Campanula** *perſicæfolia, flore albo. Mor. Hiſt.* The white Peach-leav'd Bell-flower.
4. **Campanula** *perſicæfolia, flore pleno. Tourn.* The double Peach-leav'd Bell-flower.
5. **Campanula** *perſicæfolia, flore albo pleno. Tourn.* The double white Peach-leav'd Bell-flower.
6. **Campanula** *hortenſis flore & folio oblongo. C. B.* Garden Bell-flower with oblong Leaves and Flowers; *commonly called, Canterbury* Bells.
7. **Campanula** *hortenſis flore & folio oblongo, flore albo. C. B.* White *Canterbury* Bells.
8. **Campanula** *hortenſis flore & folio oblongo, flore variegato.* The ſtrip'd *Canterbury* Bells.
9. **Campanula** *vulgatior, foliis urticæ, vel major & aſperior, flore duplici cœruleo majore. Boerh. Ind.* Large Nettle-leav'd Bell-flower with large double blue Flowers.
10. **Campanula** *vulgatior foliis urticæ, vel major & aſperior, flore duplici albo. H. R. Par.* Large Nettle-leav'd Bell-flower, with double white Flowers.
11. **Campanula** *Canarienſis, atriplicis folio, tuberoſa radice. Tourn. Canary* Bell-flower, with Orach Leaves, and a tuberoſe Root.
12. **Campanula** *minor Americana, foliis rigidis, flore cœruleo patulo. H. L.* Dwarf *American* Bell-flower, with rigid Leaves, and blue Flowers.
13. **Campanula** *minor Americana, foliis rigidis, flore albo. H. H. L.* Dwarf *American* Bell-flower, with rigid Leaves, and white Flowers.
14. **Campanula** *radice eſculenta, flore cœruleo. H. L.* Blue Bell-flower, with edible Roots, *commonly called* Rampions.
15. **Campanula** *arvenſis procumbens. Inſt. R. H. Venus*'s Looking-glaſs, *vulgo.*
16. **Campanula** *arvenſis erecta. H. L.* Upright *Venus*'s Looking-glaſs.
17. **Campanula** *arvenſis erecta, flore albo. Inſt. R. H.* Upright *Venus*'s Looking-glaſs, with a white Flower.
18. **Campanula** *arvenſis procumbens, flore albo. H. L. Venus*'s Looking-glaſs, with a white Flower.
19. **Campanula** *maxima, foliis latiſſimis, flore cœruleo. C. B. P.* Greateſt Bell-flower, with broad Leaves, and a blue Flower, commonly called Giant Throatwort.
20. **Campanula** *maxima, foliis latiſſimis, flore albo. C. B. P.* Greateſt Bell-flower, with broad Leaves, and a white Flower.
21. **Campanula** *pratenſis, flore conglomerato. C. B. P.* Little Throatwort, or *Canterbury* Bells, *vulgo.*
22. **Campanula** *pratenſis, flore conglomerato, albo. H. R. Par.* Little-Throatwort, or *Canterbury* Bells, with a white Flower.

23. Campanula *foliis echii, floribus villoſis.* C. B. Bell-flower with Leaves like Vipers-bugloſs, and hairy Flowers.

24. Campanula *foliis anchuſæ, floribus oblongis.* C. B. Bell-flower with Leaves like Alkanet, and longiſh Flowers.

25. Campanula *nemoroſa anguſtifolia, magno flore, major.* *Inſt. R. H.* Greater wood Bell-flower, with a narrow Leaf, and large Flower.

26. Campanula *nemoroſa anguſtifolia, parvo flore.* *Inſt. R. H.* Narrow-leafed wood Bell-flower, with a ſmall Flower.

27. Campanula *minor rotundifolia vulgaris.* C. B. Common ſmall round-leafed Bell-flower.

28. Campanula *pentagonia perfoliata.* *Mor. Hiſt.* Five-corner'd Bell-flower, with a perfoliated Leaf.

The firſt Sort is commonly cultivated to adorn Chimnies, Halls, &c. in the Summer-ſeaſon; for which Purpoſe there is no Plant more proper, it producing ſometimes eight, ten, or twelve Branches, which will grow four or five Feet high, and produce large Quantities of beautiful Flowers, almoſt the whole Length of the Stalks, which, if kept from Rain and Sun, will continue in Beauty for a long time; and if the Branches are regularly ſpread flat to Sticks, makes a very fine Appearance.

This Plant is propagated either by ſowing the Seeds in *March*, in a Bed of light undung'd Soil, or by parting the Roots; the latter Method being the moſt expeditious, is commonly practiſ'd; for every Dug taken from the Roots in *September* or *March*, will grow, if rightly manag'd: But the Roots which are rais'd from Seeds, will make the ſtrongeſt Bloom; for which Reaſon, you ſhould every Year ſow of the Seeds, to have a Succeſſion of theſe Roots for Bloom, notwithſtanding they are commonly three or four Years before they flower; we ſhould therefore tranſplant the young Plants into Nurſery-beds the *September* after ſowing, which Beds ſhould be made of a light Soil, rather dry than wet: The Diſtance they ſhould be planted at, is ſix Inches ſquare: And if in hard froſty Weather you cover the Bed with Mats, it will greatly ſtrengthen the young Roots; in theſe Beds they may remain until the third Year after ſowing; at which time, if you find the Roots are ſtrong, and promiſe well for flowering, in *September* you ſhould take them up, and plant them into Pots of light Soil; and if you have the Conveniency of a Glaſs-Frame to ſhelter them in Winter from great Rains and ſevere Froſts, they will be vaſtly the ſtronger for it: For altho' they require frequent Waterings in Summer-time, yet too much Wet in Winter is apt to rot them; for their Roots are ſucculent and milky; therefore, if you have no ſuch Conveniency, you muſt lay the Pots on one Side in very wet Weather, and in a great Froſt ſet them under a warm Wall, Pale, or Hedge, and cover them with Peaſe-haulm, &c. obſerving to lay a little old Dung round the Pots, to guard their Roots from the Froſt. If this Care be taken, the Flowers will ſufficiently recompenſe for the Trouble, in their Numbers and Largeneſs.

The Peach-leav'd *Bell-Flowers* may be rais'd from Seeds, in the ſame manner; or be increas'd, by parting their Roots in Autumn, which is the moſt expeditious Method: Theſe are very hardy, and may be planted in open Beds or Borders, where they will flower very ſtrong, eſpecially if their Roots are taken up and parted every other Year; for otherwiſe, the Number of Heads will render their Stems weak, and the Flowers ſmall.

The *Canterbury Bells* are biennial, ſeldom laſting longer than the ſecond Year; theſe therefore are only rais'd, by ſowing their Seeds, the beſt Seaſon for which is in the Beginning of *April*, and in *June* the Plants will be fit to tranſplant; at which time you ſhould prepare a Bed or two in a ſhady Situation, where you muſt plant them at about ſix Inches Diſtance every way; and in *September* following you may plant them out into the Borders of the Flower Garden, where they will flower the *May* following; and when they have ripened, their Seeds will die; therefore you muſt ſow every Year, to have a Supply of freſh Roots.

The two Dwarf *American* Kinds are only propagated by Offſets, their Seeds ſeldom ripening with us; they are hardy, and will endure in the open Air, provided they are planted in a dry Soil, and a warm Situation: The beſt Seaſon for parting their Roots, is in *April*; but they muſt not have too rich a Soil.

The *Canary Campanula* is one of the moſt beautiful Plants of the Green-houſe, it producing its Flowers in the Depth of Winter, and continuing them through the Months of *December*, *January*, and *February*. This Plant is propagated by parting its Roots, the Seaſon for which is in *June*, when the Stems are quite decay'd; and in doing of it, great Care ſhould be taken, not to break or bruiſe their Roots, which would endanger their decaying. The Soil in which theſe Roots ſhould be planted, muſt be one third freſh Earth, a third part Sand, and the reſt Lime-rubbiſh; this ſhould be well mix'd and ſcreen'd, and, if laid together half a Year before it is uſed, that it may incorporate, it will be the better.

When you plant the Roots, give them a little Water to ſettle the Earth about them; but afterwards let your Waterings be ſparingly done, and but ſeldom repeated until their Stems begin to advance; after which, they muſt have it a little freely: For want of this Caution, many of theſe and other Flower-roots which are kept in Pots, are deſtroy'd; for it is impoſſible to ſuppoſe that a Root which is intirely at Reſt, and deſtitute of Leaves, ſhould be capable of diſcharging any Quantity of Moiſture; therefore let this Caution be conſtantly obſerv'd. The Stems of the Flower will begin to appear in *Auguſt*; and if the Roots are ſtrong, will riſe to eight or nine Feet in height; and in *November*, or ſooner, will begin to ſhew its beautiful flame-colour'd Flowers. When theſe Stems begin to advance, we ſhould remove the Plant into Shelter, to guard it from Morning Froſts, or great Rains; and as the Weather grows colder, it muſt be remov'd into a good Green-houſe, where it ſhould have as much free Air as poſſible in open mild Weather. This Plant will require the ſame Proportion of Heat as is allotted for the *Ficoides*, and will thrive in the ſame Houſe better than amongſt *Orange-trees*, &c.

The *nettle-leav'd Bell-flowers* are very hardy, and may be increas'd by parting their Roots either in Spring or Autumn, and are proper for large open Borders.

The *Rampion* is propagated in the Kitchen-Garden, for its Root, which was formerly in greater Eſteem in *England* than at preſent, altho' the *French* are ſtill very fond of it: The Seeds of this Plant ſhould be ſown in *March*, in a Bed of light dry Earth, as thin as poſſible; and in *May*, when the Plants are come up, hough them out, leaving them about four Inches Square; and during the Summer keep them clear from Weeds, and the Winter following they will be fit for Uſe.

The two dwarf *American* Sorts will endure our common Winters in the open Air; but in ſevere Froſts they are often deſtroyed: Therefore it will be proper to preſerve ſome Plants of each Sort in Pots, which may be placed under a common Hot-bed Frame in Winter; obſerving to take off the Glaſſes every Day in mild Weather, that they may enjoy as much free Air as poſſible; and in hard Froſts the Glaſſes may be covered with Mats, Straw, or Peaſe-Haulm, to prevent the Earth in the Pots from being frozen, which will preſerve the Plants in Vigour.

The four Sorts of *Venus*'s Looking-glaſs are annual Plants; the Seeds of theſe ſhould be ſown in the Borders of the Flower-garden, where they are to remain; for they do not love tranſplanting. If the Seeds are ſown in *April*, the Plants will flower in *June* and *July*; but if they are ſown in *May*, they will not flower till *Auguſt*: ſo that by ſowing them at different Times, there may be a Succeſſion of them in flower during all the Summer Months; and if the Seeds are ſown toward the End of *Auguſt*, upon a light warm Soil, the Plants will abide the Winter, and flower early the Spring following. The Seeds of the firſt Sort are very common in all the Seed-ſhops in *London*: the fourth is a Variety of the firſt; but the ſecond and third Sorts are leſs common in *England*.

All the other Sorts (except the laſt) are very hardy Plants, which abide many Years, and will grow in ſhady Places under the Drip of Trees; ſo that they are very proper to plant in Wilderneſs Quarters, where they will thrive, and produce their Flowers every Year; ſo will afford an agreeable Variety in ſuch Parts of the Garden, where few other Plants will thrive.

They may be propagated by ſowing of their Seeds on a Bed of freſh Earth in the Spring; and when the Plants are come up, they ſhould be tranſplanted into Beds in the Flower-nurſery, obſerving to water them, until they have taken new Root; after which Time they will require no farther Care, but to keep them clear from Weeds. At *Michaelmas* they may be tranſplanted into the Places where they are deſigned to remain; where they will continue many Years, and will increaſe by their Roots, by which Method they may alſo be propagated.

The laſt Sort is an annual Plant, which may be propagated in the ſame Manner as the *Venus*'s Looking-glaſs; but being a larger Plant, ſhould be allowed more Room to grow. If the Seeds of this Plant are permitted to fall on the Ground, the Plants will come up the following Spring, and thrive without any other Culture but keeping them clear from Weeds.

CAMPHORA: [This is call'd *Caphura* or *Camphora* by the *Latins*, and *Capur* and *Caphur* by the *Arabians*: This Tree is call'd *Camphora Officinarum*, or *Camphire of Japan.*] The Camphire-Tree.

The *Characters* are;

It hath Leaves like thoſe of the Pear-Tree, but are full of Ribs, which grow alternately upon the Branches: The Flowers conſiſt of one Leaf, which is divided into five or ſix Segments: The Fruit is ſhap'd like a Nut; the Shell is tender, and the Kernel bifid.

Camphora *officinarum. C. B.* The Camphire-Tree.

The Authors who have treated of this Tree, ſuppoſe there are two Sorts of it, one of which is a Native of the Iſle of *Borneo*, and is the Tree from whence the beſt *Camphire* is taken, which is ſuppos'd to be a natural Exudation from the Tree, produced in ſuch Places where the Bark of the Tree has been wounded or cut. The other Sort is a Native of *Japan*, which Dr. *Kempfer* deſcribes to be a Kind of *Bay*, bearing black or purple Berries, and from whence the Inhabitants of the Province of *Satzuma*, and the Iſland of *Gotho*, prepare their *Camphire*, which is procur'd by making a ſimple Decoction of the Root and Wood of this Tree cut into ſmall Pieces: But this Sort of *Camphire* (he ſays) is extremely cheap, being in Value eighty or an hundred Times leſs than the true *Bornean Camphire*.

This Tree is at preſent very rare in *Europe*, and is only increas'd by laying down the Branches, which are commonly two or three Years before they take Root, ſo as to be fit to remove: It requires a light Soil, and frequent Waterings in warm Weather, but in Winter you muſt do it ſparingly: It muſt be kept in a moderate Warmth in Winter, but in Summer may be expos'd to the open Air in a well-ſhelter'd Place.

CAMPHORATA, Stinking Ground-pine.

The *Species* are;

1. **Camphorata** *hirſuta. C. B.* Hairy ſtinking Groundpine.
2. **Camphorata** *glabra. C. B.* Smooth ſtinking Groundpine.

Theſe Plants grow plentifully on ſandy and rocky Soils near *Montpelier*, as alſo in *Italy* and *Spain*; but are ſeldom cultivated in Gardens.

The firſt Sort is reckoned amongſt the official Plants in the College Diſpenſatory; but at preſent is ſeldom uſed in Medicine.

They may be propagated by Slips, which ſhould be planted in a ſhady Border in *April*, juſt as the Plants begin to ſhoot, obſerving to water them frequently; and when the Slips have taken good Root, they may be tranſplanted (with a Ball of Earth to their Roots) into a warm dry Border, or elſe into Pots, that they may be ſheltered in ſevere Froſts, otherwiſe they will be deſtroyed.

They may alſo be propagated by Seed; but as they ſeldom perfect their Seeds in this Country, ſo the other Method is always uſed to propagate them here.

CAMPION. *Vide* Lychnis.

CANDLE-BERRY-TREE. *Vide* Gale.

CANDY-TUFT. *Vide* Thlaſpi.

CANNA INDICA. *Vide* Cannacorus.

CANNABIS [Κάνναβις, *Gr.*] Hemp.

The *Characters* are;

It hath digitated (or finger'd) Leaves, which grow oppoſite to one another; the Flowers have no viſible Petals; it is Male and Female, in different Plants.

Cannabis *ſativa. C. B.* The Manured Hemp.

This Plant is propagated in the rich fenny Parts of *Lincolnſhire*, in great Quantities, for its Bark, which is ſo uſeful for Cordage, Cloth, &c. and the Seeds afford an Oil which is uſed in Medicine.

This Plant is propagated from Seeds, which ſhould be ſown early in the Spring, on a rich moiſt Soil, which is not too ſtiff; about three Buſhels of this Seed will ſow an Acre. In chuſing of the Seeds, obſerve to take the beſt coloured, and the heavieſt, and crack ſome of them, to ſee if their Kernels are full and plump, otherwiſe it will not grow. When the Plants are come up, they ſhould be houghed out in the ſame Manner as is practiſed for *Turnips*, leaving the Plants a Foot or ſixteen Inches apart; obſerve alſo to cut all the Weeds, which if well performed, and in dry Weather, will deſtroy 'em. This Crop will require a ſecond Houghing about a Month after the firſt, in order to deſtroy the Weeds; if this be well performed, it will require no farther Care; for the Hemp will ſoon after cover the Ground, and prevent the Growth of Weeds.

The firſt Seaſon for pulling the Hemp, is uſually about the middle of *Auguſt*, when they begin to pull what they call the *Fimble-Hemp*, which is the Male Plants; but it would be much the better Method, to defer this a Fortnight or three Weeks longer; until theſe Male Plants have fully ſhed their Duſt, without which the Seeds will prove abortive, produce nothing if ſown the next Year, nor will thoſe concerned in the Oil-mills give any Thing for them, there being only empty Huſks, without any Kernels to produce the Oil.

The ſecond pulling is a little after *Michaelmas*, when the Seeds are ripe; this is uſually called *Karle-Hemp*, it is the Female Plants, which were left, at the Time when the Male were pulled. This *Karle-Hemp* is bound in Bundles of a Yard Compaſs, according to Statute Meaſure, which are laid in the Sun for a few Days to dry, and then it is ſtack'd up or houſed to keep it dry, till the Seed can be thraſhed out. An Acre of Hemp on a rich Soil will produce near three Quarters of Seed, which together with the unwrought Hemp, is worth from ſix to eight Pounds.

CANNABINA, Baſtard-hemp.

The *Characters* are;

It is a Genus, whoſe Flowers have no Petals; but conſiſt of a Number of Threads, and are barren: for the Seed is produced on Female Plants, which have no viſible Flower; but have membranaceous Seed-veſſels, which incloſe triangular Seeds, which are for the moſt part oblong.

The *Species* are;

1. **Cannabina** *Cretica fructifera. Tourn. Cor.* Fruitful Baſtard-hemp of *Candy*.
2. **Cannabina** *Cretica florifera. Tourn. Cor.* Male Baſtard-hemp of *Candy*.

Theſe two Plants both ariſe from the ſame Seeds (as is the Caſe with the Male and Female Plants of the common Hemp). They are Natives of the *Archipelago*, from whence Dr. *Tournefort* ſent the Seeds to the Royal Garden at *Paris*. They are hardy Plants, which may be propagated by ſowing their Seeds on a Bed of light freſh Earth in the Spring; and when the Plants are come up two Inches high, they ſhould be carefully tranſplanted into a Bed of freſh Earth, obſerving to ſhade and water them, until they have taken new Root; after which Time they will require no farther Culture, but to keep them clear from Weeds. At *Michaelmas* the Plants will die down to their Roots; ſo they ſhould remain in theſe Beds until the Beginning of *March*, at which Time they ſhould be tranſplanted out where they are to remain; where they ſhould be placed at a good Diſtance from each other, or any other Plants; for they grow pretty large, and will form large Heads, if they are ſuffered to remain many Years; ſo that they ſhould be planted at leaſt three Feet aſunder.

In the native Places of their Growth they often riſe to the Height of ten or twelve Feet; but in *England* they ſeldom grow to more than half that Size: but when their Roots are very ſtrong, they will ſend forth ſix or eight Stems from each Root, ſo that they will occupy a large Space of Ground; but as there is no great Beauty in theſe Plants, ſo there ſhould be but few of them admitted for Variety.

CANNACORUS, [ſo call'd of *Canna* a Stem; and *Acorus*, becauſe it has a Root and Leaves like the *Acorus*.] The *Indian* Reed.

The *Characters* are;

It hath a knobbed tuberoſe Root: The Leaves are long and nervous: The Flower conſiſts of one Leaf, is tubulous, and cut into ſix Segments; theſe are ſucceeded by roundiſh membranaceous Veſſels, which are divided into three Cells, each containing two or three round hard Seeds.

The *Species* are;

1. **Cannacorus** *latifolius vulgaris. Tourn.* The common broad-leav'd *Indian* Reed, with pale Flowers.
2. **Cannacorus** *latifolius vulgaris, foliis variegatis.* The common *Indian* Reed, with ſtrip'd Leaves.
3. **Cannacorus** *flore luteo punctato. Tourn.* The yellow ſpotted *Indian* Reed.

4. Cannocorus *flore coccineo ſplendente. Tourn.* The fine ſcarlet-colour'd *Indian* Reed.

5. Cannacorus *ampliſſimo folio, flore rutilo. Tourn.* The largeſt-leav'd *Indian* Reed, with reddiſh-colour'd Flowers.

6. Cannacorus *anguſtifolius, flore flaveſcente. Tourn.* Narrow-leav'd *Indian* Reed, with yellow Flowers.

Theſe Sorts are all propagated by Seeds, which muſt be ſown on a Hot-bed in *March*, and afterwards ſhould be tranſplanted into Pots fill'd with good rich Earth, and, during the Summer Seaſon, muſt be plentifully water'd: Theſe Plants, thus manag'd, will many Times produce Flowers the firſt Seaſon; but 'tis not till the ſecond Year that they blow ſtrong: In order to which, you ſhould houſe them before the Froſt pinches their Leaves, obſerving to give them but little Water in the Winter, and keep them intirely from the Froſt: In *May* following, prepare a good rich Bed of Earth, and turn your Plants out of the Pots into this Bed, being careful not to diſturb the Earth about their Roots, giving them Water plentifully in dry Weather; and when your Roots have once faſten'd themſelves into this Bed, they will grow vigorouſly, and produce many ſtrong Stems, which will flower much ſtronger than thoſe kept in Pots, and ripen their Seeds very well.

The Scarlet Bloſſom is by far the moſt beautiful Kind; but a Mixture of the yellow ſpotted Sort will look very agreeable; but the common pale-colour'd Sort is hardly worth keeping, unleſs in *Botanick* Collections.

Theſe Sorts may be alſo increaſ'd by parting their Roots in the Spring, but theſe Plants ſeldom flower ſo well as Seedlings: And ſince the Seeds are ſo eaſy to be obtain'd, 'tis hardly worth practiſing, unleſs for the ſtrip'd leav'd Sort, which can be no other Way increaſ'd. The Inhabitants of *America* call this Plant *Indian-ſhot*, and ſay, the *Indians* make Uſe of this Seed inſtead of Shot, to ſhoot Wild-fowl, &c.

There is alſo another *Species* of this Plant, the Root of which is the *Curcuma* of the Shops; but this I have not as yet ſeen in the *Engliſh* Gardens.

CAPERS; *vide* Capparis.

CAPILLAMENTS; [*Capillamenta*, Lat.] the Strings or Threads about the Roots of Plants.

CAPILLARY *Plants*; [of *Capillaris*, Lat. of, or like Hair] are ſuch Plants as have no main Stem, but their Leaves ariſe from the Root upon Pedicles, and produce their Seeds on the Back of their Leaves.

CAPITULUM; *i. e.* a little Head; the Head or Top of any flowering Plant.

CAPNOIDES; [ſo call'd from the *Greek* καπνὸς *Fumitory*, and εἶδος *Shape*, on account of its Reſemblance to Fumitory.] Podded Fumitory.

The *Characters* are;

The Leaves and whole Face of this Plant is like Fumitory, *but the Style of the Flower becomes a long taper Pod, which contains many round ſhining Seeds.*

Capnoides. *Tourn.* Podded Fumitory.

This is a pretty annual Plant, which may be ſown in an open Border in the Spring of the Year; and when the Plants are come up, they may be remov'd and planted in the Borders of the Flower Garden, where they will make a pretty Shew for two or three Months together: The Seeds of this Plant, if ſuffer'd to ſhed upon the Ground, will furniſh you with Plants enough, without giving you the Trouble to ſow it any more.

CAPNORCHIS; *Indian* Bulbous-rooted Fumitory.

The *Characters* are;

This hath the whole Face of Fumitory: *The Root is ſometimes tuberoſe, ſometimes ſcaly, and at other times bulbous; the Flower conſiſts of two Leaves, is of an anomalous Figure, and hangs downward; the Pods are like thoſe of* Shepherd's-Pouch.

Capnorchis *Americana. Boerh. Ind.* American bulbous-rooted Fumitory.

This Plant is propagated by parting its Roots, or from Seeds: It is not hardy enough to endure our Winters in the open Ground, ſo muſt be put into Pots filled with light Earth, and houſed in Winter: The Flowers are ſomewhat like thoſe of *Fumitory*, and tho' none of the moſt beautiful Plants, yet deſerves a Place in a good Garden.

CAPPARIS; [Κάππαρις, *Gr. to deſire.*] The Caper-Buſh.

The *Characters* are;

Its Flowers conſiſt of four Leaves, which are expanded in Form of a Roſe; *the Fruit is fleſhy, and for the moſt part ſhap'd like a* Pear, *in which are contain'd many roundiſh Seeds.*

The *Species* are;

1. Capparis *non ſpinoſa, fructu majore. C. B.* The large-fruited Caper, without Thorns.
2. Capparis *ſpinoſa, fructu minore, folio rotundo. C. B. P.* Prickly round-leafed Caper, with a ſmall Fruit.
3. Capparis *folio acuto. C. B. P.* Sharp-leafed Caper.
4. Capparis *Americana arboreſcens, lauri folio, fructu longiſſimo. Plum. Cat. American* Tree-caper, with a Bay-leaf, and a long Fruit.
5. Capparis *alia arboreſcens, lauri foliis, fructu oblongo ovato. Plum. Cat. American* Tree-caper, with a Bay-leaf, and an oval Fruit.
6. Capparis *Americana arboreſcens, laurocerasi foliis, fructu oblongo. American* Tree-caper, with Laurel-leaves, and an oblong Fruit.

The firſt, ſecond, and third Sorts are common in the *South* of *France*, and in *Italy*, where they grow wild on the Walls, and old Ruins. At *Toulon* they cultivate theſe Plants upon the Walls, by ſowing of their Seeds in the Holes of the ſtone Walls, about three or four Feet from the Ground; ſo that the Roots of the Plants penetrate into the Joints of the Walls, and from thence draw their Nouriſhment. In *England* it is very difficult to preſerve theſe Plants, eſpecially if they are planted in Earth; for theſe Plants thrive much better in Rubbiſh: ſo that where any Perſon is deſirous to cultivate them, they ſhould be planted in Pots filled with Lime-rubbiſh and Sand, and placed into a moderate Hot-bed, to forward their making new Roots; after which time they may be expoſed in the open Air in Summer; but in Winter they muſt be ſheltered from ſevere Froſt, which will deſtroy them. The Stump of theſe Plants are generally brought over in Plenty from *Italy* every Year, by the Perſons who bring over *Orange-trees* and *Jaſmines*; ſo that they may be purchaſed from them at a moderate Price, which is far the eaſieſt Method of being furniſhed with theſe Plants; for the Seeds are not eaſily obtained from abroad, nor do they ſucceed very well with us. Altho' theſe Plants require Shelter, when planted in Pots; yet they will endure the ſevereſt Cold of our Winters, in growing in a Wall.

The fourth, fifth and ſixth Sorts, are Natives of *America*: the fourth and fifth were diſcovered by Father *Plumier* in the *French* Iſlands; but the ſixth was found by Mr. *Robert Millar*, near *Carthagena* in the *Spaniſh Weſt-Indies*, from whence he alſo ſent me the other two Kinds. Theſe three Sorts may be propagated by Seeds, which ſhould be ſown in Pots filled with light ſandy Earth, and plunged into a Hot-bed of Tanners-bark, obſerving to water the Earth frequently, to forward the Vegetation of the Seed. When the Plants are come up, they ſhould be each tranſplanted into a ſmall Pot filled with light ſandy Earth, and plunged into the Hot-bed again, obſerving to ſcreen them from the Sun, until they have taken Root; after which time they muſt have Air and Water, in proportion to the Warmth of the Seaſon. When the Plants have filled theſe ſmall Pots with their Roots, they ſhould be carefully taken out, and their Roots trimmed, and put into larger Pots, and plunged into the Hot-bed again. In Winter theſe Plants muſt be removed into the Stove, and placed in the Bark-bed, where they ſhould be treated after the manner directed for the *Guajava*; with which Management theſe Plants will ſucceed.

The Seeds of this Plant may be obtain'd from *Tholouſe* or *Leghorn*, and may be ſown upon old Walls and Buildings, where they will inſinuate their Roots between the Bricks, and endure for many Years. The Buds of theſe Flowers, before they open, are pickled for Eating.

BEAN-CAPER; *vide* Fabago.

CAPREOLATE *Plants*; [of *Capreolus*, L. the Tendril of a Vine.] Such Plants as twiſt and climb upon others by means of Tendrils.

CAPRIFOLIUM; [takes its Name of *Caper*, a *Goat*, and *Folium*, a *Leaf*, Lat. becauſe Goats eat the tender Leaves of this Plant.] Honeyſuckle.

The *Characters* are ;

It hath a climbing Stalk, which twiſts itſelf about whatſoever Tree ſtands near it: The Flowers are tubulous and oblong, conſiſting of one Leaf, which opens toward the Top, and is divided into two Lips; the uppermoſt of which is again divided into two, and the lowermoſt into many Segments; the Tube of the Flower is bent, ſomewhat reſembling a Huntſman's Horn: They are produc'd in Cluſters, and are very ſweet.

The *Species* are ;

1. Caprifolium *non perfoliatum, floribus albis.* The wild or *Engliſh* white Honey-ſuckle.
2. Caprifolium *non perfoliatum, flore interius albo, rubro externe. Boerh. Ind.* The *Engliſh* red Honeyſuckle.
3. Caprifolium *non perfoliatum, foliis ſinuoſis. Tourn.* Oak-leav'd wild Honeyſuckle.
4. Caprifolium *non perfoliatum foliis ſinuoſis & variegatis.* The ſtrip'd Honeyſuckle with cut Leaves.
5. Caprifolium *non perfoliatum, foliis ex luteo variegatis.* The common Honeyſuckle with yellow ſtrip'd Leaves.
6. Caprifolium *Italicum perfoliatum præcox. Broſſ.* The *French* or early white Honeyſuckle.
7. Caprifolium *Italicum. Dod.* The *Italian* Honeyſuckle.
8. Caprifolium *Germanicum, flore rubello, ſerotinum. Broſſ.* Late red Honeyſuckle.
9. Caprifolium *Germanicum, floribus ſpecioſius. Dutch* Honeyſuckle.
10. Caprifolium *perfoliatum ſemper-virens floribus ſpecioſius.* Evergreen Honeyſuckle.

The firſt, ſecond and third Sorts of *Honeyſuckles* are found growing in the Hedges, in many Parts of *England*: Indeed, the third Sort is ſeldom found, and I believe is no more than an accidental Variety of the two former. I found one Plant of this Kind in the Woods near *Dulwich*, which I planted in the Phyſick Garden, where it now grows, and many of the Branches ſtill continue to produce indented Leaves; but the extreme Parts of the Tree, and all the vigorous Shoots, produce whole Leaves; ſo that the Variation from the common Sort is but ſmall. The two ſtrip'd Sorts are alſo Varieties of the common, one having whole, the other indented Leaves. The early white, *Italian*, late Red, and *Dutch* Sorts, are Foreigners; but have been more cultivated in the Nurſeries about *London*, than thoſe which are of our own Growth, and are much commoner in the Gardens than thoſe. The early white is the firſt Sort that flowers, commonly beginning in *April*; this is ſucceeded by the *Italian*: Then the *Dutch* and late Red Sorts follow; the latter of which, during the time of flowering, is the moſt beautiful of all the Kinds; for its Flowers are produced in very cloſe Bunches, and every Shoot of the Tree produces many Bunches, which flowering all together, renders it a very fine Shrub: but this ſeldom laſts more than a Fortnight in Beauty; whereas the *Dutch* Sort, which produces its Bunches but thinly (its Branches growing more diffuſed) continues flowering until prevented by froſty Weather. The Evergreen *Honeyſuckle* begins to produce its Flowers at the Beginning of *June*, and often continues flowering 'till *Michaelmas*, which, together with its evergreen Leaves, renders it a very valuable Shrub.

All theſe Sorts of *Honeyſuckles* are propagated by laying down their Branches in the *Spring*; which by *Michaelmas* following (if they have been ſupply'd with Water) will have taken Root, ſo as to be fit to remove, which ſhould be into Nurſery-beds, for a Year or two the better to train them up, either for Headed-plants, or for Creepers to plant againſt Trees, Walls, Pales, *&c.* which in two Years Time, at moſt, will be fit for any of thoſe Purpoſes; or they may be propagated by planting Cuttings of the young Shoots, either at *Michaelmas*, or early in the *Spring* of the Year, in a ſhady Border, where they may continue 'till the *Michaelmas* following, when they may be tranſplanted into Nurſery-beds, (as was before directed): But the evergreen *Honeyſuckle* is difficult to increaſe this Way, therefore it would be better to propagate it by *Layers*.

Theſe Shrubs are very great Ornaments to ſmall Quarters of flowering Shrubs, when train'd up to regular Heads, and the different Varieties being intermix'd therewith: Their long Continuance in Flower, together with the Beauty and Sweetneſs of their Flowers, renders them as valuable Shrubs for ſuch Purpoſes as any we have; and they are no leſs valuable for planting againſt the Stems of old Trees in Groves or Avenues, where, if they are not too much overſhaded by the Trees, they will thrive and flower exceedingly.

The beſt Seaſon for cutting theſe Trees, to keep them in a regular Form, is about *Michaelmas*, ſoon after they have done flowering, that their Wounds may heal before Winter: And this Work is beſt perform'd with a Knife, obſerving to cut behind a Leaf-Bud; for how long ſoever the Shoot is left beyond, it decays down to the Bud, and thereby becomes unſightly. They are all extreme hardy, except the Evergreen, which is ſuppos'd to be an *American* Plant; and is ſometimes, in very ſevere Winters, apt to ſuffer by the Froſt, if planted in a Situation too much expos'd.

CAPSICUM; [takes its Name of *Capſa*, Lat. a Cheſt, becauſe the Seeds of this Plant are included, as it were, in a little Cheſt; or elſe of κάπτω, to *bite*, becauſe it is a burning pungent Plant: It is alſo call'd, *Piper Indicum Americanum Braſilianum*, from its very ſharp Taſte; for if you eat the raw Fruit, the hot biting Taſte will laſt in the Mouth the whole Day, nor can it eaſily be got out] *Guiney* Pepper.

The *Characters* are ;

The Flowers conſiſt of one Leaf, and are expanded like thoſe of Nightſhade; the Fruit is ſoft, fleſhy, and membraneous, and divided into two or more Cells, in which are contained many flat Kidney-ſhap'd Seeds.

The *Species* are ;

1. Capsicum *ſiliquis longis propendentibus. Tourn.* Capſicum with long hanging Pods.
2. Capsicum *ſiliquis recurvis. Dod.* Capſicum with long Pods which turn up at the End.
3. Capsicum *latifolium, mali Æthiopici fructu magno compreſſo ſtriato, Americanum. Pluk.* Broad-leav'd Capſicum, with long compreſs'd ſtriated Pods, commonly call'd, *Bonnet Pepper.*
4. Capsicum *Africanum, fructu pyramidali pendulo rugoſiſſimo. African* Capſicum, with pyramidal rough hanging Pods.
5. Capsicum *Africanum, fructu pyramidali rugoſiſſimo, plerumque erecto. African* Capſicum, with pyramidal rough Pods, for the moſt part growing erect.
6. Capsicum *fructu non acri, rugoſo longo pendente rubro. Teſochilli. Hern.* Capſicum with long hanging red Pods, which are not hot.
7. Capsicum *fructu cordiformi, plerumque nutante rubro.* Capſicum with Heart-ſhap'd red Pods, for the moſt part hanging downwards.
8. Capsicum *fructu pyramidato craſſo, plerumque erecto, rubro.* Capſicum with pyramidal thick red Pods, for the moſt part growing upright.
9. Capsicum *fructu oblongo nunc erecto, nunc nutante, rubro.* Capſicum with oblong red Pods, growing ſometimes erect, and ſometimes hanging.
10. Capsicum *fructu rotundo majore, nunc erecto, nunc nutante, rubro.* Capſicum with large round red Pods, growing ſometimes erect, and ſometimes hanging.
11. Capsicum *fructu flavo pyramidato oblongo, nunc erecto, nunc nutante.* Capſicum with oblong pyramidal yellow Pods, growing ſometimes erect and ſometimes hanging.
12. Capsicum *fructu cordiformi, nunc erecto, nunc nutante, flavo.* Capſicum with Heart-ſhap'd yellow Fruit, growing ſometimes erect, and ſometimes hanging.
13. Capsicum *fructu olivario erecto.* Upright Olive-ſhap'd Capſicum.
14. Capsicum *fructu parvo pyramidali erecto rubro. Sloan.* Capſicum with ſmall red Pods growing erect, call'd by the Inhabitants of the *Weſt-Indies*, *Barbary*-Pepper.
15. Capsicum *fructu parvo rotundo acerrimo. Sloan.* Capſicum with ſmall round Pods which are very hot, call'd by the Inhabitants of the *Weſt-Indies*, Bird-Pepper.
16. Capsicum *Americanum, fructu rotundo Ceraſorum forma. Pluk. American* Capſicum, with round Cherry-ſhap'd Fruit.
17. Capsicum *Americanum, latifolium, fructu oblongo erecto candido.* Broad-leav'd *American* Capſicum, with oblong white Pods growing erect.
18. Capsicum *fructu maximo oblongo rugoſo, plerumque nutante, rubro.* Capſicum with large oblong red rough Pods, for the moſt part hanging downwards.

Theſe Sorts of *Capſicums* are ſown in many curious Gardens with other annual Plants, in Hot-beds, and require to be treated after the ſame Manner as was directed for the *Amaranthus*, and do, in the Autumn Seaſon, make a very pretty Diverſity, being intermix'd therewith: They are all tolerably hardy, and may be planted abroad, towards the latter End of *May*, or the Beginning of *June*, either in Pots or open Borders, where they will ripen their Fruits very well, except the 3d, 13th, 14th, 15th, 16th, and 17th Sorts, which are tenderer, and muſt be brought forward under Glaſſes, otherwiſe their Fruit will not come to good: The 13th, 14th, and 15th Sorts will remain for ſeveral Years, and form handſome Shrubs, if you take proper Care to preſerve them in the Stove in the

Winter; during which Seaſon their Fruits will remain and ripen, and appear very beautiful. Indeed, I believe, all the Sorts may be preſerv'd over the Winter, were we to take off a Part of their Fruits, before they are grown ſo big as to exhauſt the Strength of the Plant, and obſerve to houſe them in time: But as they perfect their Fruit ſo eaſily in one Summer, it is ſeldom practis'd but with thoſe Sorts that do not ſo readily ripen their Seeds.

The Fruit of theſe Plants, tho' at preſent of no great Uſe in *England*, yet affords one of the wholeſomeſt Pickles in the World, if they are gather'd young before their Skins grow tough. The Inhabitants of the *Weſt-Indies* eat great Quantities of this Fruit raw, not only while it is green, but alſo when it is fully ripe; at which time it is ſo very acrid as to cauſe an extraordinary great Pain in the Mouth and Throat of ſuch Perſons as are not accuſtom'd to eat of it.

The Inhabitants of the *Weſt-Indies* make great Uſe of the *Bird-Pepper*, which they dry and beat to a Powder, and mix with other Ingredients, which they keep by them at all times for Sauce, and uſe it inſtead of Pepper; of which they ſend ſome of theſe Pepper-pots to *England*, by the Name of *Cayan Butter* or *Pepper-Pot*, and are by ſome of the *Engliſh* People mightily eſteem'd.

CAPSULATE Pods; [of *Capſa*, Lat. a *Cheſt*] are the little ſhort Seed-veſſels of Plants.

CAPSULATED; incloſ'd in any thing, as a Walnut is in its green Huſk.

CARACALLA; *vide* Phaſeolus.

CARDAMINDUM; *vide* Acriviola.

CARDAMINE; [takes its Name of *Cardanum*, which is call'd *Naſturtium*; hence it is a ſmall Species of *Naſturtium*; or of κάρδαμον quaſi καρήδαμον, becauſe it diſturbs the Head; it is call'd the *Impatient Herb*, becauſe being touch'd, it diſcharges its Seeds, as it were, with a Spring.] Ladies Smock.

The *Characters* are;

The Flower conſiſts of four Leaves; which are ſucceeded by narrow Pods, which when ripe, roll up, and caſt forth their Seeds; the Leaves are for the moſt part wing'd.

The *Species* are;

1. CARDAMINE *pratenſis, magno flore purpuraſcente. Tourn.* Common Ladies Smock with purpliſh Flowers.
2. CARDAMINE *pratenſis, magno flore albo. Tourn.* Common Ladies Smock with white Flowers.
3. CARDAMINE *pratenſis magno flore pleno. Tourn.* The Double Ladies Smock.
4. CARDAMINE *impatiens, vulgo Sium minus. Ger. Emac.* Impatient Ladies Smock.
5. CARDAMINE *impatiens altera hirſutior. Raii Syn.* The other rough impatient Ladies Smock.
6. CARDAMINE *flore majore, elatior. Tourn.* Taller Ladies Smock, with a larger Flower.
7. CARDAMINE *Sicula, foliis fumariæ. Tourn. Sicilian* Ladies Smock, with Fumitary-leaves.
8. CARDAMINE *montana, aſari folio. Tourn.* Mountain Ladies Smock, with an Aſarabacca-leaf.
9. CARDAMINE *Alpina minor, reſedæ folio. Tourn.* Small Ladies Smock of the *Alpes*, with a baſe wild Rocket-leaf.
10. CARDAMINE *hirſuta, chelidonii folio, flore purpuraſcente. Tourn.* Hairy Ladies Smock, with a Celandine-leaf, and purpliſh Flower.
11. CARDAMINE *glabra, chelidonii folio. Tourn.* Smooth Ladies Smock, with a Celandine-leaf.
12. CARDAMINE *Alpina prima trifolia. Cluſ.* The firſt three-leafed Ladies Smock of the *Alpes*.
13. CARDAMINE *Græca, chelidonii folio rarius & profundius inciſo, flore albo. Tourn. Cor. Greek* Ladies Smock, with a Celandine-leaf, that has but few and deep Jags, and a white Flower.

The two firſt Sorts are common in moſt of the moiſt Meadows in *England*; they flower the Beginning of *May*; and altho' there is no great Beauty in thoſe Flowers, yet I thought proper to mention them, in order to introduce the third Sort, which is a very beautiful Plant, continuing a long Time in Flower, and is a very proper Plant for cold North Borders, or a wet Soil, where few others will grow; and hereby we may render the pooreſt and worſt Soil productive of Beauties, did we but carefully attend to the adapting proper Plants for it, and not endeavour to force it to produce Things which require a quite contrary Soil. The firſt Sort is ſometimes uſed in Medicine.

The fourth and fifth Sorts grow wild in *England*; but are ſometimes allowed a Place in Gardens for Variety-ſake. When the Seeds of theſe Plants are ripe, the Pods burſt on the firſt Touch, and ſcatter the Seeds all around. If theſe Plants are put in a ſhady Border, and permitted to ſhed their Seeds, they will maintain themſelves without any Care.

The ſixth Sort grows in marſhy Places, and in ſtanding Waters; ſo is rarely kept in Gardens.

The ſeventh Sort is not a Native of *England*, yet will endure the ſevereſt Cold of this Climate in a warm Border; where, if it is permitted to ſhed its Seeds, it will maintain its Place without any farther Care.

The other Sorts are Natives of the *Alpes* and *Pyrenean* Mountains (except the laſt, which was diſcovered by Dr. *Tournefort* in *Greece*). They are all extremely hardy: their Seeds ſhould be ſown ſoon after they are ripe, in a moiſt ſhady Situation, where the Plants will ſoon appear, and will require no other Care, but to clear them from Weeds; and if their Seeds are permitted to ſcatter, the Plants will come up better, than if ſown. Theſe Varieties are preſerved in botanic Gardens, and ſome of them merit a Place in ſome ſhady Part of every curious Garden, for their odd Manner of caſting forth their Seeds on the ſlighteſt Touch, when the Pods are ripe; which often ſurpriſes Strangers, who attempt to gather the Seeds.

CARDIACA; [of Καδίρα, *Gr.* the *Heart.*] Mother-wort.

The *Characters* are;

It hath a labiated Flower conſiſting of one Leaf, whoſe upper Lip is imbricated (with Pieces laid one over another in the manner of Tiles) and is much longer than the under Lip, which is cut into three parts. Out of the Flower-cup ariſes the Pointal, attended with four Embryo's, which afterwards become ſo many angular Seeds. To which may be added, the Flower-cup is beſet with ſmall Spines.

The *Species* are;

1. CARDIACA. *J. B.* 3. 320. Common Motherwort.
2. CARDIACA *flore albo. Tourn.* Motherwort with a white Flower.
3. CARDIACA *criſpa. Raii Hiſt.* Curled Motherwort.

Theſe Plants are preſerved in botanic Gardens for the ſake of Variety. The firſt is often found wild in *England*; but it is only near Gardens, from whence it was ejected. The ſecond is a Variety of the firſt, from which it only differs in the Colour of the Flower. The third Sort differs from the two former, in having fine curled Leaves.

All theſe are very hardy Plants, which will ſow themſelves where-ever they are introduced, ſo as to become Weeds in the Place. The Seeds of theſe Plants may be ſown the Beginning of *March*, on almoſt any Soil, or in any Situation; where the Plants will come up in *April*, and, if kept clear from Weeds, will thrive exceedingly. When they are large enough to tranſplant, they ſhould be removed, and planted eighteen Inches or two Feet aſunder, becauſe they will grow pretty large. If the Weather ſhould prove dry, when they are tranſplanted, they ſhould be watered, until they have taken new Root; after which time they will require no farther Care, than to keep them clear from Weeds; and the ſecond Year they will flower, and produce ripe Seeds. The firſt Sort, being a medicinal Plant, is pretty much cultivated in the Phyſicgardens near *London*, from whence the Markets are ſupplied with the Herb. The other two Sorts are only preſerved in botanic Gardens for the Sake of Variety.

CARDINALS FLOWER. *Vide* Rapuntium.

CARDUUS. Thiſtle.

The *Characters* are;

The Leaves grow alternately on the Branches, and are prickly, and the Heads are for the moſt part ſquamoſe and prickly.

The *Species* are;

1. CARDUUS *albis maculis notatus, vulgaris. C. B.* The milky or holy Thiſtle.
2. CARDUUS *nutans. J. B.* The muſk or nodding Thiſtle.
3. CARDUUS *eriocephalos. Dod.* The woolly-headed Thiſtle.
4. CARDUUS *galactites. J. B.* 3. 54. The milky Thiſtle.
5. CARDUUS *humilis alatus, ſive Carduus Mariæ, annuus, folio lituris obſcuris notato. H. Cath.* Dwarf annual Ladiesthiſtle, with winged Stalks, and dark ſpotted Leaves.

6. CARDUUS *tomentoſus, acanthi folio, vulgaris. Tourn.* Common Cotton Thiſtle.

7. CARDUUS *ſtellatus, ſive Calcitrapa. J. B.* Common Star-thiſtle.

8. CARDUUS *ſtellatus, ſive Calcitrapa, flore albo. H. R. Par.* Star-thiſtle with a white Flower.

9. CARDUUS, *ſeu Polyacantha vulgaris. Tourn.* The ſuppoſed true Fiſh-thiſtle.

10. CARDUUS *Creticus tomentoſus, acanthi folio, flore magno purpuraſcente. Tourn. Cor.* Woolly Thiſtle of *Candy*, with an Acanthus Leaf, and a large purpliſh Flower.

Theſe Sorts of Thiſtles grow wild in many Parts of *England*; the firſt commonly upon the Sea Coaſts, but the ſecond uſually upon arable Land in many Places; the laſt is leſs common than either of the former, being found but in few Places in *England*. Theſe, and all the other Sorts of Thiſtles, may be cultivated by ſowing their Seeds in the Spring in almoſt any Soil, and will flower and ſeed the ſecond Year, and ſoon after periſh, moſt of them being biennial Plants: The firſt Sort is ſometimes uſed in Medicine, and is call'd in the Diſpenſatory *Carduus Mariæ*.

The fourth Sort grows in *Spain*, *Italy*, and the South of *France*; but will not endure the Cold of our Winters, unleſs in a dry Soil, and a warm Situation.

The fifth Sort is a Native of *Sicily*; but if once planted in a Garden, and ſuffered to ſhed its Seed, will maintain its Place.

The ſixth Sort is very common upon the Sides of dry Banks, and other uncultivated Places in diverſe Parts of *England*. Of this Kind there are a great Variety in *France*, *Spain*, *Italy*, and other warm Countries: many of which have been introduced into the botanic Gardens for the ſake of Variety; but are not allowed a Place in any other Gardens.

The ſeventh Sort is found on Dunghils, and the Sides of Banks in ſeveral Parts of *England*. This Plant is greatly uſed in *France*, as a medicinal Herb; and is judged febrifugous, vulnerary, and aperitive: of late Years it has been introduced amongſt the medicinal Plants in *England*; but the Virtues are not ſo generally known, as in *France*, where it has been long in Uſe.

All theſe Plants delight to grow on barren uncultivated Places; ſo whoever hath a mind to cultivate any of the Species, ſhould ſow their Seeds on a Bed of light undunged Earth in the Spring of the Year, where they are deſigned to remain; for they do not thrive ſo well, when they are tranſplanted. When the Plants are come up, they ſhould be thinned, ſo as to leave them eighteen Inches or two Feet aſunder; and if they are kept clear from Weeds, it is all the Culture which they will require. The ſecond Year they will flower in *June* and *July*, and in *Auguſt* they will perfect their Seeds, and the Roots will ſoon after decay; ſo that to have a Succeſſion of theſe Plants, their Seeds muſt be ſown every Year.

The ninth Sort is ſomewhat tenderer than the others; ſo ſhould have a warmer Situation; otherwiſe it will be deſtroyed, if the Winter ſhould prove ſevere. This doth not ſpread ſo much as the other Kinds; but will grow upright to the Height of four or five Feet; and having Leaves regularly placed on the Stalks, from the Ground to their Heads, makes an agreeable Appearance, and merits a Place in a Garden, for the ſake of Variety.

CARDUUS BENEDICTUS; *vide* Cnicus.

CARDUUS FULLONUM; *vide* Dipſacus.

CARLINA, The Carline Thiſtle.

The *Characters* are;

It hath for the moſt part a radiated Flower, from whoſe Diſk ariſe many Florets, which reſt upon the Embryo's; but the plain Petals, which ariſe from the Crown, have no Embryo's fixed to them: the Flower-cup is large and prickly, incloſing the Embryo's. Theſe Embryo's afterward become Seeds, which have a Down adhering to them, and each is ſeparated by an imbricated Leaf.

The *Species* are;

1. CARLINA *acaulos, magno flore albo. C. B.* Carline Thiſtle without Stalks, and a large white Flower.

2. CARLINA *acaulos, magno flore purpureo. C. B.* Carline Thiſtle without Stalks, and a large purple Flower.

3. CARLINA *ſylveſtris vulgaris. Cluſ.* Common wild Carline Thiſtle.

4. CARLINA *acaulos, flore magno, radice perenni, Montis Aurei. H. R. Par.* Perennial Carline Thiſtle without Stalks, of *Mount d'Or*.

5. CARLINA *acaulos gummifera. C. B. P.* Gum-bearing Carline Thiſtle without Stalks, commonly called the white Chameleon.

6. CARLINA *cauleſcens, magno flore albicante. C. B. P.* Stalky Carline Thiſtle, with a large whitiſh Flower.

7. CARLINA *cauleſcent, magno flore rubente. C. B. P.* Stalky Carline Thiſtle, with a large reddiſh Flower.

8. CARLINA *polycephalus alba. C. B. P.* Many-headed white Carline Thiſtle.

9. CARLINA *ſylveſtris, flore aureo, perennis. H. L.* Wild perennial Carline Thiſtle, with a golden Flower.

10. CARLINA *ſylveſtris minor Hiſpanica. Cluſ. H.* Leſſer wild *Spaniſh* Carline Thiſtle.

11. CARLINA *patula, atractylidis folio & facie. Tourn.* Low ſpreading Carline Thiſtle, with a Leaf and the Face of Diſtaff Thiſtle.

12. CARLINA *umbellata Apula. Tourn.* Umbellated Carline Thiſtle of *Apulia*.

Theſe Plants grow in the South of *France*, in *Spain*, and in *Italy*: the third Sort grows wild in *England*, upon chalky Hills, and on uncultivated Places.

All theſe Plants are preſerved by the Curious in Botany, for the ſake of Variety; but they are ſeldom introduced into other Gardens, as they are Plants of no great Beauty, nor are they of any Uſe, (except the fifth Sort, which is placed in the Catalogue of Simples annexed to the College Diſpenſatory, but is rarely ordered in Medicine) ſo far as I could ever diſcover: yet, as they are ſometimes cultivated by curious Perſons, ſo it was thought proper to enumerate their ſeveral Varieties.

They may all be propagated by ſowing of their Seeds in the Spring on a Bed of freſh undunged Earth, where they are deſigned to remain; for, as they ſend forth tap Roots, ſo they will not bear tranſplanting ſo well as moſt other Plants. When the Plants appear above-ground, they ſhould be carefully weeded; and, as they grow in Size, ſo they ſhould be thinned, where they are too cloſe, leaving them about ten Inches or a Foot aſunder. The ſecond Year moſt of theſe Plants will flower: but, unleſs the Summer proves dry, they rarely produce good Seeds in *England*; and as moſt of them decay ſoon after they have flowered, ſo it is pretty difficult to maintain theſe Plants in this Country.

CARNATION; *vide* Caryophillus.

CARPINUS; [ſo call'd of *Carpere*, Lat. *to crop*, becauſe it may be eaſily cropp'd, or its Wood is eaſily cleft.] The Hornbeam or Hardbeam Tree.

The *Characters* are;

It hath Leaves like the Elm *or* Beech Tree: *The Katkins (or Male-flowers) are plac'd at remote Diſtances from the Fruit on the ſame Tree; and the outward Shell of the Fruit is winged.*

The *Species* are;

1. CARPINUS. *Dod.* The common Hornbeam Tree.

2. CARPINUS *foliis ex luteo variegatis.* The ſtrip'd Hornbeam.

3. CARPINUS *ſeu Oſtrya, Ulmo ſimilis, fructu racemoſo, Lupulo ſimilis. C. B.* The Hop Hornbeam.

4. CARPINUS *Virginiana floreſcens. Pluk.* The Virginian flowering Hornbeam.

The firſt of theſe Trees is often cultivated in the Nurſeries to make Hedges for Wilderneſſes and Orangeries; but of late it hath not been ſo much uſed for that Purpoſe, the decay'd Leaves of the Tree continuing on all the Winter, as do thoſe of the *Oak*, rendering them very unſightly in a Pleaſure-Garden, which, together with the perpetual Litter their Leaves make, have almoſt brought them into Diſuſe for this Work, unleſs in large Wilderneſſes, where the Hedges are train'd up to a great Height, for which Purpoſe there is no Tree more uſeful, it being a very tonſile Plant, and may be kept thick from the Bottom to the Height of eighteen or twenty Feet, and will reſiſt the Violence of ſtrong Winds the beſt of any of the deciduous Trees, and is of ſpeedy Growth. The Timber of this Tree is very tough and flexible, and is of excellent Uſe to the Turners, as alſo for making Millcogs, Heads of Beetles, &c. and is very good Fire-wood.

Theſe Trees may be rais'd from the Seeds, which ſhould be ſown early in the *Autumn* in a ſhady Situation, where they will remain in the Ground until *Spring*, and often till the ſecond Year before they appear; for which Reaſon it is generally propagated by Layers, which is the moſt expeditious Method: The Layers ſhould be laid in *Autumn*, and will have taken ſufficient Root to be tranſplanted the *Autumn* following; at which Time they ſhould be tranſplanted into a Nurſery for two or three

Years, where, if they are deſign'd for Hedges, their under Branches ſhould not be taken off, but the Trees train'd flat for that Purpoſe. Theſe Trees are very proper to make Hedges round the Quarters of Exotick Trees and Shrubs; their Leaves abiding till the Spring before they fall off, will greatly fence off the cold Winds from the Quarters, and what Leaves do fall away in *Autumn* ſhould be ſuffer'd to remain upon the Surface of the Ground until Spring, which will keep the Froſt from penetrating ſo deep into the Ground as it would were the Ground intirely bare.

This Tree will grow upon cold barren expos'd Hills, and in ſuch Situations that few other Trees will, and make large Timber Trees, ſo that it may be cultivated to great Advantage in ſuch Places.

The *Hop-Hornbeam* ſheds its Leaves in Winter, with the *Elm*, and other deciduous Trees. This Tree, though but lately known in *England*, yet is very common in *Germany*, growing promiſcuouſly with the common Sort. This is much preferable to the common Sort for Hedges in a Pleaſure-Garden, upon the account of its quitting its Leaves, with other Trees, and thereby doth not make ſo much Litter in the Spring as the other, and will cut full as well.

The *Virginian* flowering *Hornbeam* is ſtill leſs common than the laſt, and only to be ſeen in curious Gardens; it is equally as hardy as the other, and may be increas'd by *Layers*.

CARROTS; *vide* Daucus.

CARTHAMUS; [ſo call'd of καθαίρειν, Gr. *to purge*, becauſe the Seeds of it are Purging.] Baſtard Saffron.

The *Characters* are;

This Plant agrees with the Thiſtle, in moſt of its Characters; but the Seeds of this are always deſtitute of Down.

CARTHAMUS *officinarum flore croceo. Tourn.* Baſtard Saffron or Saf-flower.

This Plant is very much cultivated in many Parts of *Germany* for the Dyers Uſe, and is brought into *England* from thence; it is there ſown in the open Fields in the Spring of the Year; and when come up, they hough it out thin, as we do Turnips, leaving the Plants, about eight or ten Inches diſtant every Way: Theſe Plants, as they grow, divide into a great many Branches, each producing a Flower at the Top of the Shoot, which, when fully blown, they cut or pull off, and dry it, which is the Part the Dyers make uſe of: And this is ſometimes mix'd with Saffron; to which (if it be rightly dry'd, and artfully mix'd) it is ſo alike, as not to be diſtinguiſhed, but by good Judges.

This Plant was formerly cultivated in *England*, particularly in *Glouceſterſhire*, where, I have been informed it ſucceeded very well: Tho' I am ſatisfy'd it muſt be a very good Seaſon if it ripens Seeds well in *England*; for the Flower-Heads are ſo cloſe and compact, that if, in the Seaſon of the Seed's Formation, there happens to be wet Weather, this enters the Boſom of the Florets, and is ſeldom dry'd away before the tender Seeds are deſtroy'd; and altho' the Seeds ſhall many times ſeem very fair and good to outward Appearance, yet, upon breaking them, they are hollow, and deſtitute of Kernels. This Seed is ſometimes uſed Medicine; therefore ſuch People as purchaſe it for that Purpoſe, ſhould be careful that they be found. The Florets of this Plant (which are the Parts the Dyers uſe) have been ſometimes put into Puddings, to colour them; and at the Time when it was cultivated in *England*, the poorer Sort of People in the Country us'd to gather it for that Purpoſe, until they put in ſuch Quantities into their Puddings, that it purged them, which occaſion'd their leaving it off.

CARUI, [ſo call'd of Κὰρ, Gr. the *Head*, as tho' good for the Head; but others derive the Name from *Caria*, where the Ancients found this Plant.] Caraway.

The *Characters* are;

It hath winged Leaves, which are cut into ſmall Segments, and are placed oppoſite on the Stalks, having no Foot-ſtalk; the Petals of the Flowers are bifid, and ſhap'd like a Heart; the Seeds are long, ſlender, ſmooth, and furrow'd.

The *Species* are;

1. CARUI. *Cæſalp.* The common Caraway.
2. CARUI *ſemine majore. Vaill.* The large ſeeded Caraway.
3. CARUI *foliis tenuiſſimis, Aſphodeli radice. Tourn.* The narroweſt-leav'd Caraway, with Aſphodel Roots.
4. CARUI *Alpinum. C. B.* Alpine Caraway.

The firſt of theſe Sorts is ſometimes found wild in *England*, in rich moiſt Paſtures, eſpecially in *Holland* in *Lincolnſhire*. The other Sorts have been ſent from Abroad, and are only cultivated in curious Gardens of Plants.

Theſe Sorts may be all cultivated by ſowing their Seeds in the Spring of the Yenr in a moiſt rich Soil; and when the Plants are come up, they ſhould be hough'd out to about ſix Inches ſquare, which will greatly ſtrengthen them, and promote their ſeeding plentifully: In the Autumn their Seeds will ripen, at which Time the Plant ſhould be cut up, and laid upon Mats to dry; and then it may be beaten out and dry'd, when it may be put up for Uſe. Theſe Seeds are uſed in Medicine, as alſo in the Confectionary, for making Seed-cakes, *&c.* The firſt Sort only is what's uſed; tho' the Seeds of the ſecond ſeem to be full as good, and are much larger and fairer than the firſt. The other Sorts are only kept in Collections of Plants for the ſake of Variety.

CARYOPHYLLATA; [ſo call'd, becauſe the Root being taken out of the Ground and pounded, early in the Spring, breathes out the fragrant Scent of the *Clove-gilliflower*. It is by the *Italians* call'd *Herba Benedicta*, i. e. *Bleſſed Herb*, on account of its manifold Virtues: We read nothing of this Name among the Ancients; but the Moderns have ſo call'd it. *Boerhaave* ſays, He does not know whether this Plant was known to the Ancients. It is alſo call'd *Sana Mundi*, as tho' it could heal or cleanſe the whole World.] Avens or Herb-Bennet.

The *Characters* are;

It hath pennated (or winged) Leaves ſomewhat like thoſe of Agrimony: The Cup of the Flower conſiſts of one Leaf, which is cut into ten Segments; the Flower conſiſts of five Leaves, which ſpread open in Form of a Roſe; the Seeds are form'd into a globular Figure, each of which hath a Tail to it; the Roots are perennial, and ſmell ſweet.

The *Species* are;

1. CARYOPHYLLATA *vulgaris. C. B.* Common Avens.
2. CARYOPHYLLATA *montana flore luteo magno. J. B.* Mountain Avens with large yellow Flowers.
3. CARYOPHYLLATA *montana purpurea. Ger. Emac.* Mountain Avens with purple Flowers.
4. CARYOPHYLLATA *montana flore luteo nutante. C. B.* Mountain Avens with yellow binding Flowers.
5. CARYOPHYLLATA *Alpina, Chamædryos folio. Hiſt. Oxon.* Mountain Avens with Germander Leaves.
6. CARYOPHYLLATA *vulgaris majore flore. C. B.* Avens with large Flowers.
7. CARYOPHYLLATA *pentaphyllæa. J. B.* Cinquefoil-Avens.
8. CARYOPHYLLATA *Virginiana, albo flore minore radice inodora. H. L. Virginian* Avens with ſmall white Flowers, whoſe Roots have no Scent.

The firſt, third, fourth, fifth, ſixth and ſeventh Sorts are found growing wild in *England*, *Scotland* and *Ireland*; but the ſecond Sort was brought from the *Alps*, and the eighth from *Virginia*: Theſe Sorts may be all cultivated in a Garden, by tranſplanting their Roots from the Places of their Growth, into a moiſt ſhady Part of the Garden, where they will thrive exceedingly; which is the beſt Method to procure them, for their Seeds commonly remain two Years in the Ground before they appear. The firſt Sort (which is that commonly uſed in Medicine) is ſo common in *England*, that it hardly deſerves a Place in a Garden; but the ſecond, third, fourth and ſixth Sorts are worthy a Place in ſome moiſt ſhady Border where few other Things will grow; and ſerve to add to the Variety, eſpecially ſince they require no Care or Trouble in their Culture, but only every *Michaelmas* to divide and tranſplant their Roots.

CARYOPHYLLUS; [ſo call'd, from their having the Scent of *Cloves*] Clove-gilliflowers or Carnations.

The *Characters* are;

It hath an intire oblong, cylindrical, ſmooth Cup, which is indented at the Top; the Petals of the Flower are narrow at Bottom, and broad at the Top, and are for the moſt part lacinated (or cut) about the Edges; the Seed-veſſel is of a cylindrical Figure, containing many flat rough Seeds.

This Genus may be divided into three Claſſes, for the better explaining them to Perſons unacquainted with *Botany*; which alſo will be as neceſſary for the right underſtanding their Culture.

1. **Caryophyllus** *hortenſis.* The Clove-gilliflower or Carnation.
2. **Caryophyllus** *tenuifolius plumarius*, or Pinks.
3. **Caryophyllus** *barbatus*, or Sweet-Williams.

I ſhall treat of theſe three Claſſes ſeparately, that I may the better explain their ſeveral Methods of Culture: And firſt, I ſhall begin with the *Carnation* or *Clove-gilliflower*; theſe the Floriſts diſtinguiſh again into four Claſſes.

The firſt they call *Flakes*; theſe are of two Colours only, and their Stripes are large, going quite through the Leaves.

The ſecond are call'd *Bizarrs*; theſe have Flowers, ſtrip'd or variegated with three or four different Colours.

The third are call'd *Piquettes*; theſe Flowers have always a white Ground, and are ſpotted (or pounced, as they call it) with ſcarlet, red, purple, or other Colours.

The fourth are call *Painted Ladies*; theſe have their Petals of a red or purple Colour on the upper-ſide, and are white underneath.

Of each of theſe Claſſes there are numerous Varieties; but chiefly of the *Piquettes*, which of late Years have been in greater Eſteem than any of the other Kinds. To enumerate the Varieties of the chief Flowers in any one of theſe Claſſes, would be needleſs, ſince every Country produces new Flowers almoſt every Year; ſo that thoſe Flowers which at their firſt raiſing were greatly valu'd, are in two or three Years become ſo common, as to be of little Worth, eſpecially if they are defective in any one Property. Therefore (where Flowers are ſo liable to Mutability, either from the Fancy of the Owner, or that better Kinds are yearly produced from Seeds, which, with good Floriſts, always take Place of older or worſe Flowers, which are turn'd out of the Garden, to make Room for them) it would be but ſuperfluous in this Place to give a Liſt of their Names, which are generally borrow'd either from the Names and Titles of Noblemen, or from the Perſon's Name, or Place of Abode, who rais'd it; I ſhall only beg Leave to mention two or three old deſcrib'd Sorts, by way of Introduction, and ſhall then proceed.

1. **Caryophyllus** *altilis major. C. B.* The Clove-gilliflower.
2. **Caryophyllus** *maximus ruber. C. B.* The large Baſtard Clove-gilliflower.
3. **Caryophyllus** *maximus, alter lato porri folio. H. R. Par.* The broad-leav'd Carnation or Gilliflower.

The firſt of theſe Sorts is the true Clove-gilliflower, which hath been for a long time ſo much in Uſe for making a Cordial Syrup, *&c.* of which there are two or three Varieties commonly brought to the Markets, which differ greatly in their Goodneſs; ſome of them having very little Scent, when compar'd with the true Sort: the large Kind hath been much plentier ſome Years ſince than at preſent: This uſed to burſt the Pods, and their Petals hang loping about in ſuch a manner, that the People did not care to buy them in the Market, which was the Reaſon it hath not been cultivated ſo much of late. The third Sort is only to be found in ſuch ſmall Gardens as raiſe great Quantities of theſe Flowers from Seed, to ſupply the Markets in the Spring of the Year: This being a very hardy Kind, and their Leaves being ſo broad, and the Plants ſo vigorous, that the People who are wholly unacquainted with theſe Flowers, make choice of theſe as the moſt promiſing Plants; whereas they ſeldom have more than four or five Leaves in a Flower, and thoſe are very ſmall, and ill-colour'd: The firſt of theſe, *viz.* the Clove-gilliflower, is worthy of a Place in every good Garden; but of late there have been ſo many new Kinds produc'd from Seeds, which are very fine and large, that moſt of the old Sorts have been excluded the Gardens of the Floriſts.

Theſe Flowers are propagated either from Seeds, (by which new Flowers are obtain'd) or from Layers, for the Increaſe of thoſe Sorts which are worthy maintaining: But I ſhall firſt lay down the Method of propagating them from Seed, which is thus:

Having obtain'd ſome good Seeds, either of your own ſaving, or from a Friend that you can confide in; in the Beginning of *April*, prepare ſome Pots, or Boxes (according to the Quantity of Seed you have to ſow); theſe ſhould be filled with freſh light Earth, mix'd with very rotten Neats Dung, which ſhould be well incorporated together; then ſow your Seeds thereon, (but not too thick) covering it about a Quarter of an Inch with the ſame light Earth, placing the Pots or Caſes ſo as to receive the Morning Sun only, till eleven of the Clock, obſerving alſo to refreſh the Earth with Water ſo often as it may need it: In about a Month's Time your Plants will come up, and, if kept clear from Weeds, and duly water'd, will be fit to be tranſplanted in the Beginning of *June*; at which Time you ſhould prepare ſome Beds (of the ſame Sort of Earth as was directed to ſow them in) in an open airy Situation, in which you ſhould plant them at about three Inches ſquare, obſerving to water and ſhade them, as the Seaſon may require, being careful alſo to keep them clear from Weeds: In theſe Beds they may remain until the Beginning of *Auguſt*, by which Time they will have grown ſo large as alſo to meet each other; then prepare ſome more Beds of the like good Earth, (in Quantity proportionable to the Flowers you have rais'd) in which you ſhould plant them at ſix Inches Diſtance each Way, and not above four Rows in each Bed, for the more conveniently laying ſuch of them as may prove worthy preſerving; for in theſe Beds they ſhould remain to flower.

The Allies between theſe Beds ſhould be two Feet wide, that you may paſs between the Beds to weed and clean them. When your Flowers begin to blow, you muſt look over them to ſee if any of them profer to make good Flowers; which ſo ſoon as you diſcover, you ſhould lay down all the Layers upon them: Thoſe which are well mark'd, and blow whole without breaking their Pods, ſhould be reſerv'd to plant in Borders, to furniſh you with Seed; and thoſe which burſt their Pods, and ſeem to have good Properties, ſhould be planted in Pots, to try what their Flowers will be, when manag'd according to Art: And it is not till the ſecond Year that you can pronounce what the Value of a Flower will be, which is in Proportion to the Goodneſs of its Properties: Which, that you may be well acquainted with what the Floriſts call good Properties, I ſhall here ſet down.

1. The Stem of the Flower ſhould be ſtrong, and able to ſupport the Weight of the Flower without hanging down.
2. The Petals (or Leaves) of the Flower ſhould be long, broad, and ſtiff, and pretty eaſy to expand, or (as the Floriſts term 'em) ſhould be free Flowers.
3. The middle Pod of the Flower ſhould not advance too high above the other Part of the Flower.
4. The Colours ſhould be bright, and equally mark'd all over the Flower.
5. The Flower ſhould be very full of Leaves, ſo as to render it, when blown, very thick and high in the Middle, and the Outſide perfectly round.

Having made choice of ſuch of your Flowers as promiſe well for the large Sort, theſe you ſhould mark ſeparately for Pots, and the round whole blowing Flowers for Borders; you ſhould pull up all ſingle Flowers, or ſuch as are ill-colour'd and not worth preſerving, that your good Flowers may have the more Air and Room to grow ſtrong; theſe being laid, ſo ſoon as they have taken Root, (which will be ſome Time in *Auguſt*) they ſhould be taken off, and planted out, thoſe that blow large, in Pots, and the other in Borders, (as hath been already directed.) But I ſhall now proceed to give ſome Directions for propagating theſe Flowers by *Layers*, and the neceſſary Care to be taken, in order to blow them fair and large.

The beſt Seaſon for laying theſe Flowers is in *June*, as ſoon as the Shoots are ſtrong enough for that Purpoſe, which is perform'd in the following Manner: After having ſtript off the Leaves from the lower-part of the Shoot intended to be layed, make choice of a ſtrong Joint about the middle Part of the Shoot, (not too near the Heart of the Shoot, nor in the hard Part next the old Plant) then with your Penknife make a Slit in the middle of the Shoot from the Joint upwards half way to the other Joint, or more, according to their Diſtance, then with your Knife cut the Tops of the Leaves, and alſo cut off the ſwelling Part of the Joint where the Slit is made, (which might otherwiſe prevent their puſhing out Roots); and having looſened the Earth round the Plant, and, if need be, rais'd it with freſh Mould, ſo that it may be level with the Shoot intended to be layed, leſt by forcing down the Shoot you ſplit it off, then with your Finger make a hollow Place in the Earth, juſt where the Shoot is to come, and with your Thumb and Finger bend the Shoot gently into the Earth, obſerving to keep the Top as upright as poſſible, that the Slit may be open; and being provided with forked Sticks for that Purpoſe, thruſt it into the Ground, ſo that the forked-part may take hold of the *Layer*, in order to keep it down in its proper Place; then gently cover the Shank of the *Layer* with the ſame Sort of Earth, giving it a gentle watering, to ſettle the Earth about it, obſerving to repeat the ſame as often as is neceſſary, in order to promote their rooting. In about five or ſix Weeks after this, the *Layers* will have taken Root ſufficient to be tranſplanted; againſt which Time you ſhould be provided with proper Earth for them, which may be compos'd after the following manner.

Make choice of ſome good Up-land Paſture, or a Common that is of a hazel Earth, or light ſandy Loam; dig from the Surface of this your Earth about eight Inches deep, taking all the Turf with it, let this be laid in a Heap to rot and mellow, turning it once a Month, that it may ſweeten; then mix about a third-part of rotten Neats-dung, or, for want of that, ſome rotten Dung from a Cucumber or Melon-bed; let this be well mix'd together; and if you can get it Time enough beforehand, let them lie mix'd ſix or eight Months before it is uſed, turning it ſeveral Times, the better to incorporate their Parts.

Obſerve, That altho' I have mention'd this Mixture as the beſt for theſe Flowers, yet you muſt not expect to blow your Flowers every Year equally large, in the ſame Compoſition: Therefore, ſome People who are extremely fond of having their Flowers ſucceed well, alter their Compoſitions every Year, in this Manner, *viz.* one Year they mix the freſh Earth with Neats-dung, which is cold; the next Year with rotten Horſe-dung, which is of a warmer Nature, adding thereto ſome white Sea-ſand, to make the Earth lighter.

But for my part, I ſhould rather adviſe the planting two or three *Layers* of each of your beſt Kinds in a Bed of freſh Earth not over-dung'd; which Plants ſhould only be ſuffer'd to ſhew their Flowers, to prove them right in their Kind; and when you are ſatisfied in that Particular, cut off the Flower Stems, and don't ſuffer them to ſpend the Roots in blowing; by which means you'll greatly ſtrengthen your *Layers*. And it is from theſe Beds I would make choice of ſome of the beſt Plants for the next Year's blowing, always obſerving to have a Succeſſion of them yearly; by which means you may blow every Year fine, ſuppoſing the Seaſon favourable: For it is not reaſonable to ſuppoſe that the *Layers* taken from ſuch Roots as have been exhauſted in producing large Flowers, and have been forc'd by Art beyond their natural Strength, ſhould be able to produce Flowers equally as large as their Mother-Root did the Year before, or as ſuch *Layers* as are freſh from a poorer Soil, and in greater Health, can do. But this being premis'd, let us proceed to the potting of theſe *Layers*, which (as I ſaid before) ſhould be done in *Auguſt*.

The common Method uſed by moſt Floriſts, is, to plant their *Layers*, at this Seaſon, two in each Pot, (the Size of which Pots are about nine Inches over in the Clear at the Top); in theſe Pots they are to remain for Bloom; and therefore, in the Spring of the Year, they take off as much of the Earth from the Surface of the Pots as they can, without diſturbing their Roots, filling the Pots up again with the ſame good freſh Earth as the Pots were before fill'd with. But there is ſome Difficulty in ſheltering a great Quantity of theſe Flowers in Winter, when they are planted in ſuch large Pots, which in moſt Winters they will require, more or leſs; my Method therefore is, to put them ſingly into Halfpenny Pots in Autumn, and in the Middle of *October* to ſet theſe Pots into a Bed of old Tanners-bark which has loſt its Heat, and cover them with a common Frame (ſuch as is uſed for raiſing Cucumbers and Melons); and in one of theſe Frames, which contains three Lights, may be ſet an hundred and fifty of theſe Pots: In theſe Frames you may give them as much free Air as you pleaſe, by taking off the Lights every Day when the Weather is mild, and putting them on in bad Weather, and great Rains: And if the Winter ſhould prove ſevere, it is but only covering the Glaſſes with Mats, Straw, or Peaſe-haulm, which will effectually preſerve your Plants in the utmoſt Vigour.

In the Middle of *February*, if the Seaſon is good, you muſt tranſplant theſe Layers into Pots for their Bloom (which ſhould be about ſeven Inches over at the Top in the Clear); in the doing of which, obſerve to put ſome Pot-ſherds or Oyſter-ſhells over the Holes in the Bottoms of the Pots to keep the Earth from ſtopping them, which would detain the Water in the Pots to the great Prejudice of the Flowers; then fill theſe Pots about half way with the ſame good Compoſt as was before directed, and ſhake the Plants out of the ſmall Pots with all the Earth about the Roots; then, with your Hands, take off ſome of the Earth round the Outſide of the Ball, and from the Surface, placing one good Plant exactly in the Middle of each Pot, ſo that it may ſtand well as to Height, *i. e.* not ſo low as to bury the Leaves of the Plant with Earth; nor ſo high that the Shank may be above the Rim of the Pot; then fill the Pot up with the Earth before-mention'd, cloſing it gently to the Plant with your Hands, giving it a little Water, if the Weather is dry, to ſettle the Earth about it; then place theſe Pots in a Situation where they may be defended from the North Wind, obſerving to give them gentle Waterings, as the Seaſon may require.

In this Place they may remain till about the Middle of *April*, at which Time you ſhould prepare a Stage of Boards to ſet the Pots upon, which ſhould be ſo order'd, as to have little Ciſterns of Water round each Pot, to prevent the Inſects from getting to your Flowers in their Bloom; which if they are ſuffer'd to do, will mar all your Labour, by deſtroying all your Flowers in a ſhort Time: The chief and moſt miſchievous Inſect in this Caſe, is, the Earwig, which will gnaw off all the lower Parts of the Petals of the Flowers, (which are very ſweet) and thereby cauſe the whole Flower to fall to Pieces: But ſince the making one of theſe Stages is ſomewhat expenſive, and not very eaſy to be underſtood by ſuch as have never ſeen them, I ſhall therefore deſcribe a very ſimple one, which I have uſed for ſeveral Years, which anſwers the Purpoſe full as well as the beſt and moſt expenſive one can do: Firſt, prepare ſome common flat Pans, about a Foot over, and three Inches deep; place theſe two and two oppoſite to each other, at about two Feet Diſtance; and at every eight Feet in length-ways, two of theſe Pans; in each of theſe whelm a Flower-pot, which ſhould be about ſix Inches over at the Top, upſide-down, and lay a flat Piece of Timber, about two Feet and a half long, and three Inches thick, croſs from Pot to Pot, till you have finiſh'd the whole Length of your Stage; then lay your Planks lengthways upon theſe Timbers, which will hold three Rows of Planks for the Size-pots which were order'd for the *Carnations*: And when you have ſet your Pots upon the Stage, fill the flat Pans with Water, always obſerving, as it decreaſes in the Pans, to repleniſh it, which will effectually guard your Flowers againſt Inſects.

This Stage ſhould be plac'd in a Situation open to the South-Eaſt, but defended from the Weſt Winds, but ſhould not be too near Trees, Walls, nor Buildings. About this Time, *viz.* the Middle of *April*, your Layers will begin to ſhoot up for Flower; you muſt therefore be provided with ſome ſquare Deal Sticks about four Feet and a half long, which ſhould be thicker toward the Bottom, and planed off taper at the Top: Theſe Sticks ſhould be carefully ſtuck into the Pots as near as poſſible to the Plant without injuring it; then with a ſlender piece of Baſs-mat faſten the Spindle to the Stick to prevent its being broke: This you muſt often repeat, as the Spindle advances in Height; and alſo obſerve to pull off all ſide Spindles as they are produc'd, and never let more than two Spindles remain upon one Root, nor above one, if you intend to blow exceeding large. Toward the Beginning of *June* your Flowers will have attain'd their greateſt Height, and their Pods will begin to ſwell, and ſome of the earlieſt begin to open on one Side: you muſt therefore obſerve to let it open in two other Places at equal Angles: This muſt be done ſo ſoon as you perceive the Pod break, otherwiſe your Flower will run out on one Side, and be paſt recovering, ſo as to make a complete Flower in a ſhort time; and in a few Days after the Flowers begin to open, you muſt cover them with Glaſſes which are made for that purpoſe, in the following manner:

Upon the Top of the Glaſs, exactly in the Center, is a Tin Collar or Socket about three Fourths of an Inch ſquare, (this is for the Flower-ſtick to come through); to this Socket are ſoldered eight Slips of Lead at equal Diſtances, which are about ſix Inches and a half long, and ſpread open at the Bottom about four Inches aſunder; into theſe Slips of Lead are faſten'd Slips of Glaſs, cut according to the Diſtances of the Lead, which when they are fix'd in, are border'd round the Bottom with another Slip of Lead quite round, ſo that the Glaſs hath eight Angles with the Socket in the Middle, and ſpread open at the Bottom about eleven Inches.

When your Flowers are open enough to cover with theſe Glaſſes, you muſt make a Hole through your Flower-ſtick exactly to the Height of the under part of the Pod, through which you ſhould put a Piece of ſmall Wire about ſix Inches long, making a Ring at one End of the Wire to contain the Pod, into which Ring you ſhould fix the Stem of the Flower; then cut off all the Tyings of Baſs, and thruſt the Stem of the Flower ſo far from the Stick, as may give convenient Room for the Flower to expand without preſſing againſt the Stick; to which Diſtance you may fix it by turning your Wire ſo as not to draw back thro' the Hole; then make another Hole thro' the Stick, at a convenient Diſtance above the Flower, thro' which you ſhould put a Piece of Wire, an Inch and a half long, which is to ſupport the Glaſſes from ſliding down upon the Flowers; and be ſure to obſerve, that the Glaſſes are not plac'd ſo high as to admit the Sun and Rain under them to the Flowers, nor ſo low as to ſcorch their Leaves with the Heat. At this time alſo, or a few Days after, as you ſhall judge neceſſary, you ſhould cut ſome ſtiff Paper, Cards, or ſome ſuch Thing, into Collars about four Inches over, and exactly round, cutting a Hole in the Middle of it about three Fourths of an Inch Diameter, for the Bottom of the Flower to be let through; then place theſe Collars about them to ſupport the Petals of the Flower from hanging down: This Collar ſhould be plac'd withinſide the Calyx of the Flower, and ſhould be ſupported thereby: Then obſerve from Day to Day what Progreſs your Flowers make; and if one Side comes out faſter than the other, you ſhould turn the Pot about, and ſhift the other Side towards the Sun; and alſo if the Weather proves very hot, you ſhould ſhade the Glaſſes in the Heat of the Day with Cabbage-leaves, *&c.* to prevent their being ſcorch'd, or forc'd out too ſoon; and when the middle Pod begins to riſe, you ſhould take out the Calyx thereof with a Pair of Nippers made for that Purpoſe; but this ſhould not be done too ſoon, leſt the middle part of the Flower ſhould advance too high above the Sides, which will greatly diminiſh the Beauty of it: And you ſhould alſo obſerve whether there are more Leaves in the Flower than can properly be expanded for Want of Room; in which Caſe you ſhould pull out ſome of the lowermoſt or moſt unlikely Leaves to ſpread, drawing out and expanding the others at the ſame time: And when your Flowers are fully blown, if you cut them off, you ſhould put on a freſh Collar of ſtiff Paper, which ſhould be cut exactly to the Size of the Flower, ſo that it may ſupport the Petals to their full Width, but not to be ſeen wider than the Flower in any Part: When this is put on, you muſt draw out the wideſt Leaves to form the Outſide of the Flower, which altho' they ſhould be in the Middle, (as it often happens) yet by removing the other Leaves they may be drawn down, and ſo the next longeſt Leaves upon them again, that the whole Flower may appear equally globular without any hollow Parts. In the doing of this, ſome Floriſts are ſo curious as to render an indifferent Flower very handſome; and on this depends, in a great meaſure, the Skill of the Artiſt to produce large fine Flowers.

During the flowering Seaſon, particular Care ſhould be taken not to let them ſuffer for want of Water, which ſhould by no means be raw Spring-water; nor do I approve of Compound-waters, ſuch as are inrich'd with various Sorts of Dung, but the beſt and moſt natural Water is that of a fine ſoft River; next to that is Pond-water or Standing-water; but if you have no other but Spring-water, it ſhould be expos'd to the Sun or Air two Days before it is uſed, otherwiſe it will give the Flowers the Canker, and ſpoil them. Thus having been full in the Culture of this noble Flower, I ſhall juſt mention that of the *Pink*, which differs not in the leaſt from that of the *Carnation* in its manner of propagating, but only requires much leſs Care, and need not be potted, growing full as well in good Borders, where they make as elegant a Shew during their Seaſon of Flowering, as any Plant whatever, and afford as agreeable a Scent. The Varieties of theſe are,

The *Damask Pink*, *White Shock*, *Scarlet*, *Pheaſant's-ey'd Pink*, of which there are great Varieties, both with ſingle and double Flowers, the *Old Man's Head*, and the *Painted Lady Pinks*, with ſeveral others. Theſe may be propagated by *Layers* as the *Carnations*, and many of them by Cuttings planted in *July*, or from Seeds, by which Method new Varieties may be obtain'd. The manner of ſowing theſe Seeds being the ſame with the *Carnations*, I ſhall refer back to that, to avoid Repetition, and ſhall proceed to the *China Pink*, which is a Flower of later Date amongſt us than any of the former; which altho' it hath no Scent, yet for the great Diverſity of beautiful Colours which are in theſe Flowers, with their long Continuance in Flower, do merit a Place in every good Garden.

1. CARYOPHYLLUS *Sinenſis ſupinus, leucoii folio, flore vario. Tourn.* The variable *China* or *Indian* Pink.
2. CARYOPHYLLUS *Sinenſis ſupinus, leucoii folio, flore pleno. Boerh. Ind.* The double *China* Pink.

There is a great Variety of different Colours in theſe Flowers, which vary annually as they are produc'd from Seeds, ſo that in a large Bed of theſe Flowers, ſcarcely two of them are exactly alike, and their Colours in ſome are exceeding rich and beautiful; we ſhould therefore be careful to ſave the Seeds from ſuch Flowers only that are beautiful, for they are very ſubject to degenerate from Seeds.

And the Seeds of the double Sort will produce many double Flowers again; but the Seeds of the ſingle will ſcarcely ever produce a double Flower.

Theſe Flowers are only propagated by Seeds, which ſhould be ſown toward the End of *March*, in a Pot or Box of good light Earth, and ſet under a Glaſs to forward its Vegetating; giving it Water as often as you ſhall ſee neceſſary, and in about a Month's Time your Plants will come up, and be of ſome Bigneſs; you muſt therefore expoſe them to the open Air, and in a ſhort Time after prepare ſome Beds of good freſh Earth, (not too ſtiff) in which you may prick out theſe Plants, about three Inches ſquare, obſerving to water and ſhade them, as the Seaſon may require.

In thoſe Beds they may remain until the Middle of *June*, at which Time you may remove and plant them in the Borders of the Pleaſure-garden, being careful to preſerve as much Earth to their Roots as poſſible; and in a Month's Time after they will begin to flower, and continue until the Froſt prevent them. About the Middle or latter End of *Auguſt* their Seeds will begin to ripen, at which Time you ſhould look over them once a Week, gathering off the Pods that are changed brown, and ſpread them on Papers to dry, when you may rub out the Seed, and put it up for Uſe. Tho' theſe Plants are uſually term'd Annuals, and ſown every Year; yet their Roots will abide two or three Years, if ſuffer'd to remain, and will endure the greateſt Cold of our Winters, if planted in a dry Soil, and without any Shelter, as I experienc'd *Anno* 1728, at which Time I had a large Bed of theſe Flowers, which was rais'd a Foot above the Level of the Ground; and altho' its Situation was ſuch that the Sun never ſhone upon it from *October* to *March*, yet I had not one Root deſtroyed in the whole Bed, altho' it ſtood open, and without any Care taken of it.

I ſhall now come to the *Sweet-Williams*, where I ſhall firſt give the Names of a few of them, and proceed to their Culture.

1. CARYOPHYLLUS *barbatus hortenſis latifolius. C. B.* The broad-leav'd Sweet William with red Flowers.
2. CARYOPHYLLUS *barbatus hortenſis latifolius, flore variegato. Boerh. Ind.* The broad-leav'd Sweet William with variegated Flowers.
3. CARYOPHYLLUS *barbatus, flore multiplici. C. B.* The double Sweet William with red Flowers, which burſt their Pods.
4. CARYOPHYLLUS *barbatus, flore multiplici roſeo. C. B.* The Roſe-coloured double Sweet William.
5. CARYOPHYLLUS *barbatus hortenſis anguſtifolius. C. B.* The narrow-leav'd Garden Sweet William, *formerly call'd* Sweet Johns.
6. CARYOPHYLLUS *barbatus hortenſis anguſtifolius, flore verſicolore in eodem ramulo. C. B.* The Sweet John, with various colour'd Flowers on the ſame Branch.
7. CARYOPHYLLUS *barbatus hortenſis anguſtifolius, flore pleno roſeo.* The double Roſe-colour'd Sweet John, or *Fairchild*'s Mule.

The ſingle Kinds of theſe Flowers are generally propagated by Seeds, which muſt be ſown in *March* in a Bed of light Earth, and in *May* they will be fit to tranſplant out; at which time you muſt prepare ſome Beds ready for them, and ſet them at ſix Inches Diſtance every way: In theſe Beds they may remain till *Michaelmas*, at which time they may be tranſplanted into the Borders of the Pleaſure-garden or Wilderneſs: Theſe will flower the next Year in *May*, and will perfect their Seeds in *July* or *Auguſt*, which you ſhould ſave from the beſt-colour'd Flowers for a Supply.

They may be alſo propagated by ſlipping their Roots at *Michaelmas*: But this is ſeldom practis'd; ſince their Seedling Roots will always blow the ſtrongeſt, and new Varieties are obtain'd yearly.

The double Kinds are propagated by *Layers*, as the *Carnations*; they love a middling Soil, not too light, nor too heavy or ſtiff; nor too much dung'd, which very often occaſions their rotting: theſe continue flowering for a long time, and are extremely beautiful, eſpecially the *Mule*, which produces two full Blooms of Flowers, one in *May*, and the other in *July*: This is very ſubject to canker and rot away, eſpecially if planted in a Soil over-wet, or too dry, or if watered with ſharp Spring-water: Theſe Flowers being planted in Pots, are very proper to adorn Court-Yards, at the time they are in Flower.

CASIA, Red-berried Shrub-caſia.

The *Characters* are;

It is Male and Female in different Plants: The Male hath Flowers conſiſting of many Stamina or Threads, without any Petals; theſe are always ſteril: The Female Plants, which have no conſpicuous Flower, produce ſpherical Berries, in which are included Nuts of the ſame Form.

The *Species* are;

1. CASIA *poetica Monſpelienſium, an Theophraſti. Lob. Icon.* 433. *Montpelier* Caſia of the Poets, according to *Lobelius*.
2. CASIA *Hiſpanica procerior, myrti folio. Tourn. Spaniſh* Caſia, with a Myrtle Leaf.

The firſt of theſe Plants grows in Plenty by the Road-ſide in *Spain*, and the South of *France*; where it riſes to the Height of three Feet, and becomes ſhrubby. This was ſuppoſed by *Lobel* to be the *Caſia* of the Poets: but it doth not well agree with the Deſcriptions we have of Caſia; by which it ſhould be a ſweet Herb, and proper to be wrought into Garlands; the Leaves ſhould alſo be inclining to White; in neither of which this Plant doth agree. There are ſome Authors, who ſuppoſe the *Caſia* to be the *Thymelæa lini folio* of *Caſpar Bauhin*: but it is very uncertain what Plant it was, which *Virgil*, in his *Georgics*,

Georgics, mentions under that Name; ſince the Epithets applied by him to the Caſia, will not agree with any Plant we at preſent are acquainted with.

The ſecond Sort was diſcovered by Dr. *Tournefort* in his Travels thro' *Spain*: this grows taller than the former Sort, and hath much broader Leaves.

Both theſe Plants may be propagated by Seeds, which ſhould be ſown in Pots or Boxes filled with freſh Earth: the Seeds ſhould be covered about half an Inch thick with the ſame Earth. If they are ſown in the Autumn ſoon after they are ripe, and the Pots or Boxes placed under a Hot-bed Frame, where they may be ſheltered from hard Froſts, the Plants will come up the following Spring: but if they are kept till the Spring before they are ſown, the Seeds will remain in the Ground a whole Year before the Plants will appear; in which Caſe you ſhould place the Pots or Boxes in a ſhady Situation during the Heat of Summer; but in Winter they muſt be removed under a Hot-bed Frame, as was before directed.

When the Plants are come up, they ſhould be kept clear from Weeds, and in dry Weather they muſt be conſtantly watered; but they ſhould remain unremoved until the following Spring. The Pots or Boxes ſhould be placed, during the Summer Seaſon, where they may have the Morning Sun till Ten of the Clock, and be ſcreened from the Sun in the Heat of the Day: but in Winter they muſt be placed under a Hot-bed Frame, to protect them from hard Froſts; for, while the Plants are ſo young, they will not endure great Cold. The following Spring, about the Beginning of *March*, theſe Plants ſhould be carefully taken up out of the Seed-pots, and each planted in a ſeparate ſmall Pot, filled with freſh Earth, that is not over-ſtrong, obſerving to water them to ſettle the Earth to their Roots; and if you place the Pots on a moderate Hot-bed, it will greatly forward the Plants, and be the moſt ſure Method to preſerve them; provided the Bed is not too hot, and you give them a ſufficient Quantity of Air. In this Hot-bed the Plants may remain until the Beginning of *May*, when you ſhould inure them to bear the open Air by degrees; for about the Middle of that Month, they muſt be removed out, and placed where they may have the Morning Sun, as was directed before.

The following Winter theſe Plants ſhould be ſheltered under a Hot-bed Frame again: but they muſt be expoſed to the open Air conſtantly in mild Weather; for they will require only to be protected from ſevere Cold. In the following Spring ſome of the Plants may be ſhaken out of the Pots, (juſt before they begin to ſhoot) and planted in the full Ground in a warm Situation; where they will endure the Cold of our ordinary Winters very well, and in a Year or two will produce their Flowers; which are ſometimes ſucceeded by Seeds, but they are ſeldom ripened in this Country: but as theſe Plants are liable to be deſtroyed in very cold Winters, ſo it will be proper to keep ſome Plants of each Kind in Pots; which may be ſheltered from the Cold, in order to preſerve the Species.

CASSIA.

The *Characters* are;

It hath a cylindrical, long, taper, or flat Pod, which is divided into many Cells by tranſverſe Diaphragms, in each of which is contain'd one hard Seed, which is for the moſt part lodg'd in a clammy black Subſtance which is purgative: The Flowers conſiſt of five Leaves, which are diſpoſ'd in an orbicular Order.

The *Species* are;

1. Cassia *Americana, foliis ſubrotundis acuminatis. Tourn.* The *American* Caſſia with roundiſh-pointed Leaves.

2. Cassia *Americana fœtida, foliis oblongis glabris. Tourn.* The ſtinking *American* Caſſia with oblong ſmooth Leaves.

3. Cassia *ſylveſtris fœtida, ſiliquis alatis. Plum. Nov. Gen.* The wild ſtinking Caſſia with wing'd Pods, *call'd in the Weſt-Indies French* Guava.

4. Cassia *Marylandica, pinnis foliorum obtuſis, radice repente.* Caſſia from *Maryland*, with blunt Leaves, and a creeping Root.

5. Cassia *Bahamenſis, pinnis foliorum mucronatis, anguſtis, calyce floris non reflexo. Mart. Hiſt. Pl. Dec.* 2. Narrow-leav'd Caſſia of the *Bahama Iſlands*, with a reflex'd Cup to the Flower.

6. Cassia *Barbadenſis, pinnis foliorum mucronatis, calyce floris non reflexo. Ibid.* Barbados Caſſia, with a reflex'd Cup, and pointed Leaves.

7. Cassia *Americana fœdita foliis obtuſis. Tourn.* Stinking *American* Caſſia with blunt Leaves.

8. Cassia *Americana, ſiliquis planis. Plum. Nov. Gen.* *American* Caſſia with ſmooth Pods.

9. Cassia *fiſtula Alexandrina. C. B.* The Purging Caſſia, or Pudding-Pipe-Tree.

Theſe Caſſia's are all propagated by Seeds, which muſt be ſown in a Hot-bed in *February*, and afterwards tranſplanted into Pots, which muſt be plung'd into another Hot-bed, and muſt be kept forward, by removing them from one Hot-bed to another (as was directed for the *Amaranths*). Nor ſhould theſe Plants be ever expos'd to the open Air, if we intend to ſee them flower; they muſt therefore be kept in a warm Stove in Winter, and be carefully manag'd: Many of theſe Plants will flower the ſecond Year, and ſome of them produce ripe Seeds with us; nay, ſometimes, many of them will flower the firſt Year, if they were ſown very early, as the fifth, ſixth, ſeventh and eighth Sorts frequently do; but then they are more apt to decay in Winter, than thoſe that do not flower: The fourth Sort will endure the ſevereſt Cold of the Winter in the open Ground, and increaſes plentifully by the Root: This produces Flowers in the Autumn; but our Summers are not warm enough to ripen their Seeds. The ninth Sort grows to be a very large Tree, not only in *Alexandria*, but alſo in the *Weſt-Indies*: This is what produces the purging Caſſia of the Shops, and may be rais'd by ſowing (freſh Seeds taken out of the Pulp) in a Hot-bed in the Spring of the Year, and muſt be manag'd as the other Sorts: This will grow with us to be a handſome Shrub, but muſt be kept in a warm Stove, otherwiſe it will not endure through the Winter. All theſe Caſſia's love a light ſandy Soil, and in warm Weather muſt be frequently water'd. The third Sort will grow to a great Height in one Seaſon, if it be forwarded in Hot-beds; but is with much Difficulty preſerv'd the Winter through: This has flower'd in *England*, but I have not heard of its producing any Seeds.

CASSIDA, [*i. e.* an *Helmet*] Skull-cap.

The *Characters* are;

The Florets are longiſh, one in each Ala of the Leaves: The Upper-Leaf is galeated (like an Helmet*) with two Auricles adjoining; the Under-leaf, for the moſt part, is divided into two: the* Calyx *having a Cover, contains a Fruit reſembling the Heel of a Slipper or Shoe; which Character, ſingly, might be ſufficient to diſtinguiſh it.*

The *Species* are;

1. Cassida *folio meliſſæ, flore purpureo longiore. Boerh. Ind.* Skull-cap with Leaves like Balm, and long purple Flowers.

2. Cassida *Cretica, fruticoſa, folio catariæ, flore albo. T. Cor.* Shrubby Skull-cap from *Crete*, with Leaves like Catmint, and white Flowers.

3. Cassida *Orientalis, altiſſima, urticæ folio. T. Cor.* The talleſt *Eaſtern* Skull-cap, with Leaves like Nettle.

4. Cassida *Orientalis, folio chamædryos, flore luteo. T. Cor.* *Eaſtern* Skull-cap with Germander Leaves, and yellow Flowers.

There are ſeveral other Varieties of this Plant, which are preſerv'd in curious Gardens of Plants; but theſe here mention'd are the moſt beautiful of them, and beſt worth preſerving in curious Gardens, for their Variety.

They may be all propagated by ſowing their Seeds in an open Bed of light Earth in *March*; and when they come up, may be tranſplanted either into Pots, for the Conveniency of ſheltering them in Winter, or into Borders under warm South Walls, where, if the Soil is dry, they will endure our common Winters abroad very well, but in hard Winters they are liable to be deſtroy'd.

The fourth Sort is the hardieſt of them all, as alſo the moſt beautiful; but this ſeldom produces good Seed in our Country: however, it is very eaſy to increaſe this Plant by Cuttings; or from young Plants, which may be obtain'd from the Branches of the old ones which lie near the Ground, and ſtrike out their Roots from the Joints.

The other three Sorts ripen their Seeds tolerably well with Us, from which young Plants may be annually obtain'd, and alſo by parting their Roots; theſe generally die down to the Surface after Seeding, and freſh Shoots ariſe from the Roots at the ſame time, ſo that the Plants are never deſtitute of green Shoots.

CASSINE. The Caſſioberry-Buſh and *South-Sea* Thea.

1. Cassine *veræ perquam ſimilis arbuſcula, Philyreæ foliis antagoniſtis, ex provincia Carolinienſi. Pluck. Mant.* The Caſſioberry-Buſh.

2. CASSINE *vera Floridanorum, arbuſcula baccifera, alaterni ferme facie, foliis alternatim ſitis, tetrapyrene. Pluk. Mant.* The *South-Sea* Thea-Tree; *vulgo.*

The firſt of theſe Trees is hardy, and will endure our ſevereſt Winters in the open Ground, after they are become woody; therefore it will be proper to ſhelter the young Plants two or three Winters while they are young; after which time they may be tranſplanted abroad in ſome well ſhelter'd Situation, upon a light Soil, where they will thrive exceedingly, and in a few Years produce Flowers. This Tree ſeldom grows to be very large, and therefore ſhould be planted among Trees of a middling Growth. The largeſt of theſe Trees which I have as yet ſeen in *England*, is now growing in the Gardens of that curious and learned Botaniſt *Charles Duboiſe*, Eſq; at *Mitcham* in *Surrey*, which is about ten Feet high, and pretty thick in the Stem; this Tree hath ſtood abroad in an open Situation for ſeveral Years, reſiſting the ſevereſt Winters, and hath flower'd many Years; but I don't remember to have heard of its producing any Fruit.

The ſecond Sort is ſomewhat tenderer than the former, and ſhould not be planted in the full Ground, until the Plants have acquir'd a conſiderable Strength; nor ſhould they be planted in a Situation too much expos'd to the cold Winds, and muſt have a dry ſandy Soil: This Sort differs from the former, in the Manner of producing its Leaves, which are placed alternately on the Branches, whereas the other produces its Leaves by Pairs oppoſite to each other. This is an Evergreen, but the Caſſioberry-buſh ſheds its Leaves in Winter.

Theſe Trees are both of them propagated by ſowing their Seeds, (which are obtain'd from *Carolina*, where they grow in great Plenty near the Sea-Coaſts;) they ſhould be ſown in Pots fill'd with light ſandy Earth, and plung'd upon a gentle Hot-bed, obſerving to water it frequently, until you ſee the Plants appear, which is ſometimes in a Month or five Weeks time, and at other times they will remain in the Ground until the ſecond Year; therefore if the Plants ſhould not come up in two Months time, you ſhould remove the Pots into a ſhady Situation, where they may remain till *October*, being careful to keep them clean from Weeds, and now and then in dry Weather giving them a little Water: Then remove theſe Pots into Shelter during the Winter Seaſon, and in the *March* following put them upon a freſh Hot-bed, which will forward the Seeds in their Vegetation.

When the Plants are come up, they ſhould by degrees be expos'd to the open Air, in order to inure them to our Climate; yet don't expoſe them to the open Sun at firſt, but rather let them have the Morning Sun only, placing them for ſome time where they may be ſhelter'd from cold Winds: They ſhould enjoy a Shelter during the two or three firſt Winters; after which, the Caſſioberry-buſh may be planted abroad: But the *South-Sea* Thea ſhould be kept in Pots a Year or two longer, being ſlower of Growth, and will therefore not have Strength enough to reſiſt the Cold when young.

They may alſo be propagated by laying the younger Branches into the Ground in the Spring, which, if kept water'd, will take Root by the ſucceeding Spring, fit for Tranſplantation; otherwiſe they'll be two Years before they take Root. The Caſſioberry-buſh is by much the eaſieſt Plant of the two to ſtrike.

The *Paraguay* or *South-Sea* Thea is accounted by the *Indians* very wholeſome, and (as I have been inform'd by ſeveral worthy Perſons who reſided for ſeveral Years in *Carolina*) is the only Phyſick the *Indians* uſe, and for which, at certain Times of the Year, they come in Droves ſome hundred Miles diſtant, for the Leaves of this Tree (it not being known to grow at any conſiderable Diſtance from the Sea): Where their uſual Cuſtom is, to make a Fire upon the Ground, and putting a great Kettle of Water thereon, they throw into it a large Quantity of theſe Leaves, and immediately ſet themſelves round the Fire, and with a Bowl that holds about a Pint, they begin drinking round large Draughts, which in a very ſhort time vomits them ſeverely; thus they continue Drinking and Vomiting for the ſpace of two or three Days, until they have ſufficiently cleans'd themſelves; then they gather every one a Bundle of the Tree to carry away with them, and retire to their Habitations. But theſe Gentlemen obſerv'd ſomething very extraordinary in the Operation of this Plant, which was, that in Vomiting, it gave them no Uneaſineſs or Pain, but came away in a full Stream from their Mouths, without ſo much as declining their Heads, or the leaſt Reaching.

Monſieur *Frezier* alſo ſays, That the *Spaniards* who live near the Gold Mines in *Peru*, are obliged frequently to drink of the Herb *Paraguay* or *Mate*, to moiſten their Breaſts, without which they are liable to a ſort of Suffocation, from the ſtrong Exhalations which are continually coming from the Mines.

The ſame Author alſo adds, That the Inhabitants of *Lima*, during the Day-time, make much Uſe of the Herb *Paraguay*, which ſome call St. *Bartholomew*'s Herb, who, they pretend, came into thoſe Provinces, where he made it wholeſome and beneficial; whereas before it was venomous: This (he ſays) is brought to *Lima* dry, and almoſt in Powder.

Inſtead of drinking the Tincture or Infuſion apart, as we drink *Tea*, they put the Herb into a Cup or Bowl made of a *Calabaſh*, tipp'd with Silver, which they call *Mate*; they add Sugar, and pour the hot Water upon it, which they drink immediately, without giving it Time to infuſe, becauſe it turns as black as Ink. To avoid drinking the Herb which ſwims at the Top, they make Uſe of a Silver Pipe, at the End whereof is a Bowl full of little Holes; ſo that the Liquor ſuck'd in at the other End is clear from the Herb. They drink round with the ſame Pipe, pouring hot Water on the ſame Herb, as it is drank off. Inſtead of a Pipe, which they call *Bombilla*, ſome part the Herb with a Silver Separator, call'd *Apartador*, full of little Holes. The Reluctancy which the *French* have ſhewn to drink after all ſorts of People, in a Country where many are Pox'd, has occaſion'd the inventing the Uſe of little Glaſs Pipes, which they begin to uſe at *Lima*. This Liquor (he ſays) in his Opinion, is better than *Tea*; it has a Flavour of the Herb, which is agreeable enough: the People of the Country are ſo uſed to it, that even the pooreſt drink it once a Day, when they riſe in the Morning.

The Trade for this Herb (he ſays) is carried on at *Santa Fé*, whither it is brought up the River of *Plate*. There are two Sorts of it; the one call'd *Yerba de Palos*; and the other, which is finer, and of more Virtue, *Yerba de Camini*: The laſt is brought from the Lands belonging to the *Jeſuits*; the great Conſumption of it is between *La Paz* and *Cuzco*, where it is worth half as much more as the other, which is ſent from *Potoſi* to *La Paz*. There come yearly from *Paraguay* into *Peru* above Fifty thouſand *Arrova's*, Twelve Thouſand Hundred Weight of both Sorts, whereof at leaſt one Third is of the *Camini*, without reckoning Twenty-five thouſand *Arrova's* of that of *Palos* for *Chili*. They pay for each Parcel, containing ſix or ſeven *Arrova's*, four Royals for the Duty call'd *Alcavala*, (being a Rate upon all Goods ſold) which, with the Charge of Carriage, being above Six hundred Leagues, doubles the firſt Price, which is about Two Pieces of Eight; ſo that at *Potoſi* it comes to about Five Pieces of Eight the *Arrova*. The Carriage is commonly by Carts, which carry an hundred and fifty *Arrova's* from *Santa Fé* to *Jujuy*, the laſt Town of the Province of *Tucuman*; and from thence to *Potoſi*, which is an hundred Leagues farther, it is carried on Mules.

What this curious Author has obſerved, on there being two Sorts of this Herb, may very well agree with thoſe two Sorts here mention'd, ſince both of them are generally ſuppoſed to agree in their Qualities, tho' one is much preferable to the other; therefore I imagine the *Yerba de Camini* is what we call *Paraguay* or *South-Sea Thea*; and the *Yerba de Palos*, to be our *Caſſioberry Buſh*, the Leaves of which are extreme bitter, eſpecially when taken green from the Tree, and the Taſte is hardly to be gotten out of the Mouth for ſome Hours after chewing a Leaf thereof. But as our Author only ſaw the dried Herb, he could no more diſtinguſh their Difference, than we can the *Thea* brought from *China*; I mean, as to the particular Trees which produce it.

CASTANEA, [takes its Name from *Caſtaneum*, a City of *Magneſia*, where this Tree antiently grew in great Plenty] The Cheſnut-tree.

The *Characters* are;

It hath Male Flowers (or Catkins) which are placed at remote Diſtances from the Fruit on the ſame Tree; the outer Coat of the Fruit is very rough, and has two or three Nuts included in each Huſk or Covering.

The *Species* are;

1. CASTANEA *ſativa. C. B.* The common *or* manured Cheſnut.

2. CASTANEA *ſativa, foliis eleganter variegatis.* The ſtrip'd Cheſnut.

3. CASTANEA *pumilis, Virginiana, racemoſo fructu parvo, in ſingulis capſulis echinato, unico. Baniſt. Pluk. Alm.* The Chinquapin *or* Dwarf *Virginian* Cheſnut.

The firſt of theſe Trees was formerly in greater Plenty amongſt us than at preſent, as may be prov'd by the old Buildings in *London*, which were for the moſt part of this Timber; and in a Deſcription of *London*, written by *Fitz-Stephens*, in

Henry the Second's Time, he ſpeaks of a very noble Foreſt, which grew on the North Part of it: *Proxime* (ſays he) *patet Foreſta ingens, ſaltus numeroſi ferarum, latebræ cervorum, damarum, aprorum, & taurorum ſylveſtrium, &c.* And there are ſome Remains of old decay'd *Cheſnuts* in the old Woods and Chaſes not far diſtant from *London*, which plainly proves, that this Tree is not ſo great a Stranger to our Climate as many People believe it to be, and may be cultivated in *England*, to afford an equal Profit with any of the larger Timber-trees, ſince the Wood of this Tree is equal in Value to the beſt *Oak*, and, for many Purpoſes, far exceeding it; as particularly for making Veſſels for all Kinds of Liquor, it having a Property (when once thoroughly ſeaſon'd) of maintaining its Bulk conſtantly, and is not ſubject to ſhrink or ſwell, as other Timber is too apt to do; and I am certainly inform'd, that all the large Caſks, Tuns, *&c.* for their Wines in *Italy*, are made of this Timber; and it is for that, and many more Purpoſes, in greater Eſteem amongſt the *Italians* than any other Timber whatever. It is alſo very valuable for Pipes to convey Water under Ground, as enduring longer than the *Elm*, or any other Wood: In *Italy* it is planted for Coppice-Wood, and is very much cultivated in Stools, to make Stakes for their Vines: which being ſtuck into the Ground, will endure ſeven Years, which is longer than any other Stakes will do, by near half the Time. The Uſefulneſs of the Timber, together with the Beauty of the Tree, renders it as well worth propagating as any Tree whatever, eſpecially in Avenues or ſmaller Plantations near a Dwelling-houſe.

Theſe Trees are propagated by planting the *Nuts* in *February*, in Beds of freſh undung'd Earth: The beſt *Nuts* for ſowing, are ſuch as are brought from *Portugal* and *Spain*, and are commonly ſold in Winter for Eating: Theſe ſhould be preſerv'd until the Seaſon for ſowing in Sand, where Mice, or other Vermin, can't come to them, otherwiſe they will ſoon deſtroy them: Before you ſet them, it will be proper to put them into Water, to try their Goodneſs, which is known by their Ponderoſity; thoſe of them that ſwim upon the Surface of the Water, ſhould be rejected as good for nothing; but ſuch as ſink to the Bottom, you may be ſure are good.

In ſetting theſe *Seeds*, or *Nuts*, the beſt Way is, to make a Rill with a Hough, (as is commonly practiſed in ſetting *Kidney-Beans)* about four Inches deep, in which you ſhould place the *Nuts*, at about four Inches diſtance, with their Eye uppermoſt; then draw the Earth over them with a Rake, and make a ſecond Rill at about ſix Inches diſtance from the former, proceeding as before, allowing ſix Rows in a Bed, with an Alley between, two Feet broad, for a Conveniency of clearing the Beds, *&c.* When you have finiſh'd your Plantation, you muſt be careful that it is not deſtroy'd by Mice, or other Vermin, which is very often the Caſe, if they are not prevented by Traps, or other Means.

In *April* theſe *Nuts* will appear above Ground; you muſt therefore obſerve to keep them clear from Weeds, eſpecially while young: In theſe Beds they may remain for two Years, when you ſhould remove them into a Nurſery, at a wider Diſtance: The beſt Seaſon for tranſplanting theſe Trees, is either in *October*, or the latter End of *February:* The Diſtance theſe ſhould have in the Nurſery, is three Feet, Row from Row, and one Foot in the Rows: You muſt be careful, in tranſplanting theſe Trees, to take them up without injuring their Roots, nor ſhould they remain long out of the Ground; but if theſe Trees have a downright Tap-Root, it ſhould be cut off, eſpecially if it be intended to remove them again: This will occaſion their putting out lateral Roots, and render them leſs ſubject to miſcarry when they are remov'd for good.

The Time generally allow'd them in this Nurſery, is three or four Years, according to their Growth; during which, you ſhould be careful to keep them clear from Weeds, obſerving alſo to prune off lateral Branches, which would retard their upright Growth; and where you find any that are diſpoſed to grow, either by their upper Bud being hurt, or from any other Accident, you may, the Year after planting (in *March)* cut them down to the lowermoſt Eye next the Surface of the Ground, which will cauſe them to make one ſtrong upright Shoot, and may be afterwards train'd into good ſtrait Trees.

But in doing of this, you muſt be careful not to diſturb their Roots, which, perhaps, might deſtroy them. Theſe Trees require no other Manure than their own Leaves, which ſhould be ſuffer'd to rot upon the Ground; and in the Spring of the Year, the Ground ſhould have a ſlight digging, when this ſhould be buried between their Roots, but not too cloſe to the Trees, which might be injurious to their young Fibres.

After having remain'd three or four Years in the Nurſery, they will be fit for tranſplanting, either in Rows for Avenues to a Houſe, or in Quarters for Wilderneſs Plantations; but if you intend them for Timber, it is by much the better Method to ſow them in Furrows, (as is practiſed for Oaks, *&c.*) and let them remain unremoved; for theſe Trees are apt to have a downright Tap-Root, which being hurt by tranſplanting, is often a Check to their upright Growth, and cauſes them to ſhoot out into lateral Branches, as is the Caſe with the *Oak*, *Walnut*, &c.

Therefore where-ever any of theſe Trees are planted for Timber, they ſhould remain unremoved; but where the Fruit of them is more ſought after, then it is certainly the better Way to tranſplant them; for as tranſplanting is a Check to the luxuriant Growth of Trees, ſo is it a Promoter of their Fructification, as may be evinced by obſerving low ſhrubby *Oaks*, *Walnuts*, &c. which generally have a greater Plenty of Fruit than any of the larger and more vigorous Trees; and the Fruit of ſuch Trees are much ſuperior in Taſte, tho' the Seeds of vigorous Trees are vaſtly preferable for Plantations of Timber; for the weaker Trees being leſs capable to furniſh a Supply of Nouriſhment, and having a greater Quantity of Fruit upon them, to which this muſt be diſtributed, together with their Roots lying near the Surface of the Ground, (by which Means the Juices are better prepared by *Sun*, *Air*, &c. before it enters their Veſſels) it is certain their Juices are better digeſted, and their Fruits better maturated, than thoſe can poſſibly be which grow upon ſtrong vigorous Trees, which have long Tap-Roots running ſeveral Feet deep into the Earth, and ſo conſequently take in vaſt Quantities of crude unprepared Juice, which is buoy'd up to the extreme Parts of the Tree; and theſe ſeldom having many lateral Branches to digeſt and prepare their Juice, by perſpiring or throwing off the crude Part before it enters the Fruits.

And this, I dare ſay, univerſally holds good in all ſorts of Fruit-trees, and is often the Occaſion of the good and bad Qualities of the ſame Sorts of Fruits growing on the ſame Soil.

What has been related about grafting this Tree into the *Walnut*, to promote their bearing, or render their Fruit fairer; or inoculating *Cherries* into the *Cheſnut*, for later Fruit, is very whimſical and ſilly, ſince neither the *Cheſnut* nor *Walnut* will receive its own Kind any other Way than by inoculating, or inarching; and it is the latter only which the *Walnut* can be propagated by; nor was it ever known that any two Trees of a different Genus would take upon each other, ſo as to produce a good Tree; therefore we may juſtly explode all thoſe different Graftings of various Trees upon each other, ſo much talk'd of by the Antients; at leaſt we may ſuppoſe thoſe Trees are not known by the ſame Names now, that they are mention'd by in their Writings; for I have made many Trials upon them, which, altho' perform'd with great Care, and in different Seaſons, yet ſcarcely one of them ſucceeded. But to return:

If you deſign a large Plantation of theſe Trees for Timber, after having twice plough'd the Ground, the better to deſtroy the Roots of Weeds, you ſhould make your Furrows about ſix Feet diſtance from each other, in which you ſhould lay the *Nuts* about ten Inches apart, covering them with Earth about three Inches thick; and when they come up, you muſt carefully clear them from Weeds: When theſe have remain'd three or four Years, (if the *Nuts* ſucceeded well) you will have many of theſe Trees to remove; which ſhould be done at the Seaſons before directed, leaving the Trees about three Feet Diſtance in the Rows; at which Diſtance they may remain for two or three Years more, when you ſhould remove every other Tree, to make Room for the remaining, which will reduce the whole Plantation to ſix Feet ſquare; then cut down every other of theſe Trees (making Choice of the leaſt promiſing) within a Foot of the Ground, in order to make Stools for Poles, which in ſeven Years Time will be ſtrong enough to lop for Hoops, Hop-poles, *&c.* for which Purpoſes they are preferable to moſt other Trees; ſo that every ſeventh Year here will be a freſh Crop, which will pay the Rent of the Ground, and all other incumbent Charges, and at the ſame Time a full Crop of growing Timber left upon the Ground: But as the large Trees increaſe in Bulk, ſo their Diſtance of twelve Feet ſquare will be too ſmall; therefore when they have grown to a Size for ſmall Boards, you ſhould fell every other Tree, which will reduce them to twenty-four Feet ſquare, which is a proper Diſtance for them to remain for good: This will give Air to the Under-wood, (which by this Time would be too much over-hung by the Cloſeneſs of the large Trees) by which means that will be greatly encouraged, and the ſmall Timber fell'd will pay ſufficient Intereſt for the Money at firſt laid out in planting, *&c.* with the Principal alſo; ſo that all the remaining Trees are clear Profit; for the Under-wood ſtill continuing, will pay the Rent of the Ground, and all other Expences; and what a fine Eſtate here will be for a ſucceeding Generation, in about fourſcore Years, I leave every one to judge.

The ſtriped-leaved *Cheſnut* is a beautiful Tree in a Garden, to intermix with various Sorts of Trees, in Clumps, or in Wilderneſs Quarters; where, by the Variety theſe fine ſtriped Trees afford, they greatly add to the Diverſity and Pleaſure of ſuch Plantations. This may be obtained by being budded upon the common *Cheſnut*.

The *Chinquapin* or Dwarf *Virginian Cheſnut*, is, at preſent, very rare in *England*; it is very common in the Woods of *America*, where it ſeldom grows above twelve or fourteen Feet high, and produces great Plenty of *Nuts*, which are for the moſt part ſingle in each outer Coat. This Tree is very hardy, and will reſiſt the ſevereſt of our Winters in the open Ground. The *Nuts* of theſe Trees, if brought from *America*, ſhould be put up in Sand ſo ſoon as they are ripe, and ſent to *England* immediately, otherwiſe they loſe their growing Quality, which is the Reaſon this Tree is at preſent ſo ſcarce with us; for not one Seed in five hundred ſent over ever grew, which was owing to the Neglect of putting them up in this Manner. This Tree will take by inarching upon the common Sort, by which it may not only be propagated, but, I believe, alſo increaſed in Magnitude.

CASTANEA EQUINA. *Vide* Hippocaſtanum.

CASTOREA.

This Plant was ſo named by Father *Plumier*, after a famous Phyſician and Botaniſt, whoſe Name was *Caſtor Durant*.

The *Characters* are;

It hath a perſonated Flower, conſiſting of one Leaf, whoſe upper Lip (or Creſt) is erect; but the Beard (or under Lip) is divided into three Parts; the middle Part is bifid: The Flower-cup afterward becomes a round fleſhy Fruit, incloſing a Shell, in which are contained four angular Seeds.

The *Species* are;

1. Castorea *repens ſpinoſa. Plum.* Prickly creeping Caſtorea.
2. Castorea *racemoſa, flore cœruleo, fructu croceo. Plum.* Branching Caſtorea, with a blue Flower, and a ſaffron-coloured Fruit.

The firſt of theſe Plants hath trailing Branches, which will creep on the Ground, if they are not ſupported; for in the Places where it grows wild, it rambles over whatever Plants grow near it. The Branches are cloſely beſet with Spines, ſomewhat like the common Bramble, ſo that it renders the Places of its Growth very difficult to paſs.

The ſecond Sort grows to the Height of ten or twelve Feet, and becomes woody: This ſends forth many Branches, at the Extremity of which there are Bunches of blue Flowers of an agreeable Scent; which are ſucceeded by ſaffron-coloured Berries, growing in Cluſters like Bunches of Currants.

Theſe Plants are Natives of the warmeſt Parts of *America*, and were firſt diſcovered by Father *Plumier*, in the *French* Settlements: But my late learned Friend, Dr. *William Houſtoun*, found them in *Jamaica*; from whence he ſent Samples of both Kinds, with their Seeds, into *England*, from which ſome of theſe Plants were raiſed.

They are both propagated by Seeds, which muſt be procured from the Places where they grow naturally; for they ſeldom perfect their Seeds in this Country. Theſe muſt be ſown in ſmall Pots filled with light freſh Earth, and plunged into a moderate Hot-bed of Tanners-bark, obſerving to water them as often as you find the Earth dry: And in the Heat of the Day, the Glaſſes of the Hot-bed ſhould be raiſed, to let the Steam paſs off; but if the Nights are cold, the Glaſſes ſhould be then covered with Mats every Evening, when the Sun is gone off the Bed. In about ſix Weeks the Plants will begin to appear; when you ſhould carefully clean them from Weeds, and frequently refreſh them with Water; and in warm Weather they ſhould have freſh Air admitted to them, that they may get Strength, and not draw up too weak. When the Plants are about two Inches high, they ſhould be carefully taken up, and tranſplanted each into a ſeparate ſmall Pot filled with freſh light Earth, and plunged into the Hot-bed again: then water them, to ſettle the Earth to their Roots; and in the Day-time the Glaſſes ſhould be ſhaded with Mats, until the Plants have taken Root; after which Time they ſhould be conſtantly watered three or four Times a Week, or ſometimes oftener, in very hot Weather; and they muſt have Plenty of Air admitted to them in the Summer Seaſon, otherwiſe they will draw up weak; but in Winter they muſt be placed in the Bark-ſtove, and treated as the Coffee-tree, and ſuch other tender exotic Plants. With this Management they will produce Flowers the ſecond or third Year, and may be contiued for ſeveral Years: and as they retain their Leaves thro' the Year, ſo they will add to the Variety in the Stove.

CATANANCE; [Κατανάγκη, *a violent Allurement to Love*, of κατα and ἀνάγκη, *Neceſſity*; or of καταναγκάζω, *to compel*; ſo call'd, becauſe of an Opinion the Antients had of it, that it was a ſtrong and almoſt invincible Inducement to Amour] Candy Lions-foot.

The *Characters* are;

The Cup of the Flower is ſquamoſe; the Florets which are round the Margin are much longer than thoſe in the Middle of the Flower; the Seeds are wrapt up in a leafy or downy Subſtance within the Cup or outer Covering.

The *Species* are;

1. Catanance *quorundam. Lugd.* True Lions-foot, with Bucks-horn Leaves.
2. Catanance *flore luteo, latiore folio. Tourn.* Broad-leav'd Candy Lions-foot, with a yellow Flower.
3. Catanance *flore luteo, anguſtiore folio. Tourn.* Narrow-leav'd Candy Lions-foot, with a yellow Flower.

The firſt of theſe Plants is a Perennial, and may be propagated by Heads taken off from the Mother Plant, either in Spring or Autumn, which are commonly planted in Pots fill'd with light ſandy Soil, in order to ſhelter them in the Winter from ſevere Froſts; but if they are planted in warm Borders, either under Walls, Pales, or Hedges, and in a moderately dry Soil, they will endure abroad very well. This Plant begins flowering in *May*, and continues till *Auguſt* or *September*, (eſpecially if the Summer is not too dry) and is a pretty Ornament to a Garden, and is eaſily kept within Bounds: It may alſo be propagated by Seeds, which ſhould be ſown in a Border of good light Earth in *March*: And in *May*, when the Plants are come up, they may be either tranſplanted into Pots or Borders, where they are to remain for flowering: but as theſe Seeds ſeldom ripen well in this Country, ſo the former Method is what is chiefly uſed in *England*.

The other two Sorts are Annuals, and therefore only propagated by Seeds, which ripen very well in this Country: The Time for ſowing them is early in *March*, in Beds or Borders of light Earth, which will come up in a Month's Time, and may then be tranſplanted into Borders to flower: Theſe flower in *June*, and perfect their Seeds in *Auguſt* or *September*.

CATAPUTIA Major. *Vide* Ricinus.

CATAPUTIA Minor. *Vide* Tithymalus.

CATARIA, [ſo call'd of *Catus*, Lat. *Cat*; becauſe Cats do not ſuffer this Plant to grow; they are very fond of it, friſk upon it, roll themſelves in it, and eat it, treating it thus out of love till it dies, as Apes who kill their Young by fondling them: Cats eating too much of this Plant grow drunk, which they do, eſpecially, when they go a Catter-wauling. It is alſo call'd *Nepeta*, of *Nepa Scorpio*, becauſe it is very good againſt the Bitings of Scorpions] Cat-Mint, *or* Nepeta.

The *Characters* are;

The Leaves are like thoſe of the Nettle, *or* Betony, *are for the moſt part hoary, and of a ſtrong Scent; the Flowers are collected into a thick Spike; the Creſt of the Flower is broad and bifid: The Lip is divided into three Segments; the middle Segment is broad, and hollow'd like a Spoon, and elegantly crenated on the Edges; each Flower is ſucceeded by four naked Seeds.*

The *Species* are;

1. Cataria *major, vulgaris. Tourn.* Common large Cat-mint.
2. Cataria, *quæ nepeta, minor, folio meliſſæ Turcicæ. H. Cath.* Leſſer Cat-mint, with Leaves like *Turkey* Balm.
3. Cataria *anguſtifolia, major. Tourn.* Narrow-leav'd large Cat-mint.
4. Cataria *Hiſpanica, betonicæ folio anguſtiori, flore cæruleo. Tourn.* Narrow-leav'd *Spaniſh* Cat-mint, with blue Flowers.
5. Cataria *Hiſpanica, betonicæ folio anguſtiori, flore albo. Tourn.* Narrow-leav'd *Spaniſh* Cat-Mint, with white Flowers.
6. Cataria *Luſitanica, erecta, betonicæ folio, tuberoſa radice. Tourn.* Upright *Portugal* Cat-mint, with a tuberoſe Root.
7. Cataria *Luſitanica, erecta, betonicæ folio, fibroſa radice. Tourn.* Upright *Portugal* Cat-Mint, with fibroſe Roots.

8. Cataria *minor, vulgaris. Tourn.* Common ſmall Cat-mint.

All theſe Sorts of *Cat-mint* are propagated by ſowing their Seeds in *February* or *March*, in Beds or Borders of common Earth, and may be afterward tranſplanted into Beds at about a Foot ſquare from each other, leaving a Path between every Bed, (which ſhould be three Feet broad) an Alley of two Feet, to go between to clear them from Weeds, *&c.*

The firſt Sort mention'd is uſed in Medicine: This may alſo be propagated by parting the Roots, either in Spring or Autumn, and will grow in almoſt any Soil or Situation: It flowers in *June*, and the Seeds are ripe in *Auguſt*. This Plant grows wild upon dry Banks in many Parts of *England*.

The other Sorts are alſo very hardy, and may be propagated in the ſame Manner, but require a dry Soil in Winter, otherwiſe they are ſubject to rot: Theſe all ripen their Seeds in *England* very well; and altho' there is no great Beauty in them, yet, for Variety, the two *Portugal* Sorts may have a Place amongſt Plants of the lower Claſs, where, if they are kept in Compaſs, and tied up to Sticks, they will make a tolerable Appearance for a long Time.

CATCH-FLY. *Vide* Lychnis.

CATERPILLARS.

There are ſeveral Kinds of this Inſect, which are very pernicious to a Garden; but there are two Sorts which are the moſt common and deſtructive to young Plants; one of them is that which the white *Butterfly* breeds: It is of a yellowiſh Colour, ſpotted with black, and commonly infeſts the tender Leaves of *Cabbages*, *Colliflowers*, and the *Indian Creſs*: This eats off all the tender Parts of the Leaves, leaving only the Fibres intire; ſo that very often we ſee, in the Autumn Seaſon, whole Gardens of Winter *Cabbages* and *Savoys* almoſt deſtroy'd by them, eſpecially in thoſe which are crowded with Trees, or are near great Buildings: Nor is there any other Method found out to deſtroy them, that I know of, but to pick them off the Plants before they are ſpread from their Neſts; by which Means, tho' perhaps many may be overlook'd, yet their Numbers will be greatly diminiſh'd: But this Work muſt be often repeated during the warm Weather, that the *Butterflies* are abroad, which are continually depoſiting their Eggs, and in a few Days Time will be metamorphoſed to perfect *Caterpillars*: But as theſe for the moſt part feed upon the outer Leaves of Plants, ſo they are more eaſily taken than the other Sort, which is much larger; the Skin is very tough, and of a dark Colour: This is call'd by the Gardeners a *Grub*, and is exceeding hurtful: The Eggs of this Sort of *Caterpillar* are, for the moſt Part, depoſited in the very Heart or Center of the Plant, (eſpecially in *Cabbages*) where after it hath obtain'd its Form, it eats its Way out thro' all the Leaves thereof; and alſo the Dung being lodged between the incloſed Leaves of the *Cabbages*, gives them an ill Scent.

This Inſect alſo burrows juſt under the Surface of the Ground, and makes ſad Havock with young Plants, by eating them thro' their tender Shanks, and drawing them into their Holes. This Miſchief is chiefly done in the Night: Whenever you obſerve this, you ſhould every Morning look over your Plat of Plants; and where-ever you ſee any Plants eat off, ſtir the Ground round about the Place with your Fingers an Inch deep, and you will certainly find them out. This is the only Method I know of deſtroying them.

CATKINS, *or* JULUS.

This is by the Botaniſts call'd, *Flos Amentaceus*: It is an Aggregate of Summits, which are join'd together in Form of a Rope or Cat's-tail, and is the Male Flower of the Trees which produce them, as the *Firrs*, *Pines*, *Cedars*, *Walnuts*, *Birch-tree*, and *Willows*.

CAUCALIS, Baſtard Parſley.

This is one of the Umbelliferous Plants, with oblong Seeds, which are a little furrow'd and prickly: the Petals of the Flower are unequal and Heart-ſhaped.

There are ſeveral *Species* of this Plant preſerved in the Botanick Gardens; but as there is no great Beauty or Uſe in any of them, ſo I ſhall paſs them over with only obſerving, that if any Perſon hath a mind to cultivate them, the beſt Seaſon to ſow their Seeds is in *Autumn*, ſoon after they are ripe; for if their Seeds are kept till *Spring*, they ſeldom produce ripe Seeds again: they are moſt of them Annual, and ſo require to be ſown every Year. We have five or ſix Species of them, which grow wild in *England*.

CAULIFEROUS *Plants*, [of *Caulis*, Lat. *a Stalk*, and *fero, to bear*] Such Plants as have a true Stalk.

CAULIS, is that which riſes ſingle above the Earth, from whence the Leaves or little Branches put forth, as *Jungius* defines it; or it is the upper Part of a Plant ſtretched forth to a Height, ſo that the Fore-parts differ not from the Hind, nor the Right from the Left: In Trees and Shrubs it is called *Caudex*; in Corn *Culmus*; the *Stalk of any Herb*; the Stem, Trunk, or Body of a Tree: *Lat.*

CEDAR of BERMUDAS: *vide* Juniperus.

CEDAR of CAROLINA: *vide* Juniperus.

CEDAR of JAMAICA: *vide* Guazuma.

CEDAR of VIRGINIA: *vide* Juniperus.

CEDRUS LIBANI, the Cedar of Libanus.

The *Characters* are;

It is ever-green; the Leaves are much narrower than thoſe of the Pine-tree, *are many of them produced out of one Tubercle, ſomewhat reſembling a Painter's Pencil; it hath Male Flowers, (or Katkins) which are produced at remote Diſtances from the Fruit on the ſame Tree; the Seeds are produced in Cones, which are large, ſquamoſe, and turbinated.*

Cedrus *magna, ſive Libani, conifera. J. B.* The Cedar of *Libanus* bearing Cones.

Many, I doubt not, will be ſurprized that I ſhould retain the Name of *Cedar* to this Tree, ſince Monſieur *Tournefort* hath placed this with the *Larch-tree*, and the Name *Cedar* being now appropriated to a Berry-bearing Tree; but I have obſerved a material Difference, in the Manner of Flowering and Fructification, between the *Larch* and this Tree: And ſince this is generally believed to be the *Cedar* mention'd in Scripture, ſo, conſequently, if Preference is given to Antiquity, this hath the greateſt Right to the Name: I ſhall therefore beg Leave to diſtinguiſh the other by the Name of *Berry-bearing Cedar*, in the next Article, and for Diſtinction ſake, this may be call'd *Cone-bearing Cedar*.

The Cones of this Tree are brought from the *Levant*, which, if preſerved intire, will continue their Seeds for ſeveral Years: the Time of their ripening is commonly in the *Spring*, and ſo conſequently are near one Year old before we receive them; for which they are not the worſe, but rather the better, the Cones having diſcharged a great Part of their Reſin by lying, and the Seeds are much eaſier to get out of them than ſuch as are freſh taken from the Tree.

The beſt Way to get the Seeds out, is to ſplit the Cones, by driving a ſharp Piece of Iron thro' the Center length-ways, and ſo pull the Seeds out with your Fingers, which you will find are faſten'd to a thin leafy Subſtance, as are thoſe of the *Firr-tree*.

Theſe Seeds ſhould be ſown in Boxes or Pots of light freſh Earth, and treated as was directed for the *Firrs* (to which I refer the Reader); but only ſhall obſerve, that theſe require more Shade in Summer than the *Firrs*, and the ſooner they are planted into the open Ground, the better.

When theſe Plants begin to ſhoot ſtrong, you will always find the leading Shoot incline to one Side; therefore if you intend to have them ſtraight, you muſt ſupport them with Stakes, obſerving to keep the Leader always cloſe tied up, until you have gotten them to the Height you deſign them, otherwiſe their Branches will extend on every Side, and prevent their growing tall.

Theſe Trees are by many People kept in Pyramids, and ſhear'd as Yews, *&c.* in which Form they loſe their greateſt Beauty; for the Extenſion of the Branches are very ſingular in this Tree, the Ends of their Shoots, for the moſt part, declining, and thereby ſhewing their upper Surface, which is conſtantly cloath'd with green Leaves in ſo regular a Manner, as to appear, at ſome Diſtance, like a green Carpet, and theſe waving about with the Wind, make one of the moſt agreeable Proſpects that can be to terminate a *Viſta*, eſpecially if planted on a riſing Ground.

It is Matter of Surprize to me, that this Tree hath not been more cultivated in *England*, than at preſent we find it; ſince it would be a great Ornament to barren bleak Mountains, where few other Trees would grow; it being a Native of the coldeſt Parts of *Mount Libanns*, where the Snow contiuues moſt Part of the Year. And from the Obſervations I have made of theſe now growing in *England*, I find they thrive beſt on the pooreſt Soil: For ſuch of them as have been planted in a ſtrong, rich, loamy Earth, have made but a poor Progreſs, in Compariſon to ſuch as have grown upon a ſtony, meagre Soil. And that theſe Trees are of quick Growth, is evident from four of them now growing in the *Phyſick-Garden* at *Chelſea*, which (as I have been credibly inform'd) were planted there in the Year 1683, and at that time were not above three Feet high; two of which Trees are at this Time, (*viz.* 1736.) upwards of ten Feet in Girt at two Feet above Ground; and their Branches extend more than twenty Feet on every Side their Trunks; which Branches (though produc'd eight or ten Feet above the Surface) do at their Termination hang very near the Ground, and thereby afford a goodly Shade in the hotteſt Seaſon of the Year.

The Soil in which theſe Trees are planted, is a lean hungry Sand, mix'd with Gravel, the Surface of which is ſcarcely two Feet deep before a hard rocky Gravel appears. Theſe Trees ſtand at four Corners of a Pond, which is brick'd up within two Feet of their Trunks, ſo that their Roots have no Room to ſpread on one Side, and ſo conſequently are crampt in their Growth: But whether their ſtanding ſo near the Water may not have promoted their Growth, I can't ſay; but ſure I am, if their Roots had *had* full Scope in the Ground, they would have made a greater Progreſs. I have alſo obſerv'd, that Lopping or Cutting of theſe Trees is very injurious to them, (more, perhaps, than to any other of the Reſinous Trees) in retarding their Growth; for two of the four Trees above-mention'd, being unadviſedly planted near a Green-houſe, when they began to grow large, had their Branches lopp'd, to let the Rays of the Sun into the Houſe, whereby they have been ſo much check'd, as at preſent they are little more than half the Size of the other two.

Theſe Trees have all of them produc'd, for ſome Years, large Quantities of *Katkins* (or Male Flowers); tho' there are but two of them which have as yet produc'd Cones; nor is it above eight or ten Years that theſe have ripen'd the Cones, ſo as to perfect the Seed: But ſince we find that they are ſo far naturaliz'd to our Country, as to produce ripe Seeds, we need not fear of being ſoon ſupply'd with Seeds enough, without depending on thoſe Cones which are brought from the *Levant*; ſince there are many Trees of this Kind in *England*, which in a few Years muſt certainly bear: But I find they are more ſubject to produce and ripen their Cones in hard Winters, than in mild ones; which is a plain Indication that they will ſucceed, even in the coldeſt Parts of *Scotland*, where, as well as in *England*, they might be propagated to great Advantage.

What we find mention'd in Scripture of the *lofty Cedars*, can be no ways applicable to the Stature of this Tree; ſince, from the Experience we have of thoſe now growing in *England*, as alſo from the Teſtimony of ſeveral Travellers who have viſited thoſe few remaining Trees on *Mount Libanus*, they are not inclin'd to grow very lofty, but, on the contrary, extend their Branches very far: To which the Alluſion made by the *Pſalmiſt* agrees very well, when he is deſcribing the flouriſhing State of a People, and ſays, *They ſhall ſpread their Branches like the Cedar Tree.*

Rouwolf, in his *Travels*, ſays, there were not at that Time (*i. e. Anno* 1574.) upon *Mount Libanus* more than 26 Trees remaining, 24 of which ſtood in a Circle; and the other two, which ſtood at a ſmall Diſtance, had their Branches almoſt conſum'd with Age: nor could he find any younger Trees coming up to ſucceed them, tho' he look'd about diligently for ſome: Theſe Trees (he ſays) were growing at the Foot of a ſmall Hill, on the Top of the Mountains, and amongſt the Snow. Theſe having very large Branches, do commonly bend the Tree to one Side, but are extended to a great Length, and in ſo delicate and pleaſant Order, as if they were trimm'd and made even with great Diligence; by which they are eaſily diſtinguiſh'd at a great Diſtance from *Firr-Trees*. The Leaves (continues he) are very like to thoſe of the *Larch-Tree*, growing cloſe together in little Bunches, upon ſmall brown Shoots.

Maundrel, in his *Travels*, ſays, There were but ſixteen large Trees remaining, ſome of which were of a prodigious Bulk, but that there were many more young Trees of a ſmaller Size; he meaſured one of the largeſt, and found it to be twelve Yards ſix Inches in Girt, and yet ſound, and thirty-ſeven Yards in the Spread of its Boughs. At about five or ſix Yards from the Ground it was divided into five Limbs, each of which was equal to a great Tree. What *Maundrel* hath related, was confirmed to me by a worthy Gentleman of my Acquaintance, who was there in the Year 1720, with this Difference only, *viz.* in the Dimenſions of the Branches of the largeſt Tree, which, he aſſur'd me, he meaſur'd, and found to be twenty-two Yards diameter. Now, whether Mr. *Maundrel* meant thirty-ſeven Yards in Circumference of the ſpreading Branches, or the Diameter of them, cannot be determined by his Expreſſions, yet neither of them well agree with my Friend's Account.

Monſieur *le Bruyn* reckons about thirty-five or thirty-ſix Trees remaining upon *Mount Libanus* when he was there, and would perſuade us it was not eaſy to reckon their Number, (as is reported of our *Stonehenge* on *Saliſbury-Plain*.) He alſo ſays, their Cones do ſome of them grow dependent. Which is abundantly confuted by the above-mention'd Travellers, as alſo from our own Experience; for all the Cones grow upon the upper Part of the Branches, and ſtand erect, having a ſtrong woody Central Style, by which it is firmly annex'd to the Branch, ſo as with Difficulty to be taken off; which Central Style remains upon the Branches after the Cone is fallen to Pieces; ſo that they never drop off Whole, as the *Pines* do.

The Wood of this famous Tree is accounted Proof againſt all Putrefaction of Animal Bodies; The Saw-duſt of it is thought to be one of the Secrets uſed by thoſe Mountebanks who pretend to have the embalming Myſtery. This Wood is alſo ſaid to yield an Oil which is famous for preſerving Books and Writings: And the Wood is thought, by my Lord *Bacon*, to continue above a thouſand Years ſound. It is alſo recorded, that in the Temple of *Apollo* at *Utica*, there was found Timber of near two thouſand Years old. And the Statue of the Goddeſs, in the famous *Epheſian* Temple, was ſaid to be of this Material alſo, as was moſt of the Timber-work of that glorious Structure.

This Sort of Timber is very dry, and ſubject to ſplit; nor does it well endure to be faſten'd with Nails, from which it uſually ſhrinks: therefore Pins of the ſame Wood are much preferable.

CEDRUS BACCIFERA. Berry-bearing Cedar.

The *Characters* are;

The Leaves are ſquamoſe, ſomewhat like thoſe of the Cypreſs; the Katkins (or Male Flowers) are produced at remote Diſtances from the Fruit on the ſame Tree; the Fruit is a Berry incloſing three hard Seeds in each.

The *Species* are;

1. Cedrus *folio Cypreſſi, major, fructu flaveſcente.* C. B. The yellow Berry-bearing Cedar.
2. Cedrus *folio Cypreſſi, media, majoribus baccis.* C. B. The *Phœnician* Cedar.

Theſe Trees are propagated by ſowing their Berries (which are brought from the *Streights*) in Boxes of light ſandy Earth, which ſhould be expos'd to the Morning-Sun only during the Summer-Seaſon, but muſt be remov'd into Shelter in Winter. Theſe Seeds ſeldom appearing till the ſecond Year, we ſhould be careful not to diſturb the Earth in the Boxes; and if in the *March* following, we put the Boxes upon a gentle Hot-bed, it will greatly forward their coming up, by which the Plants will be ſtrengthen'd before the following Winter, and ſo more likely to ſtand, tho' it will be adviſeable to ſhelter them at leaſt the two firſt Winters while they are young: The Spring following, after they are come up, you ſhould remove them into ſingle Pots, for their better tranſplanting hereafter. The beſt Seaſon for this Work is in *April*; at which Time, if you make a gentle Hot-bed in ſome cloſe Place ſhelter'd from Winds, and ſet the Pots with the freſh-planted Trees thereon, covering them with Mats for a Month or ſix Weeks, until they are ſettled and have taken freſh Roots; this will be a certain Method to make them ſtrike Root, provided they are carefully taken up without breaking their Roots: In this Place they may remain (if it is not too much expos'd to the Sun) till Autumn; at which Time the Pots ſhould be put under a *Cucumber-Frame*, ſo that in good Weather they may be expos'd to the open free Air; but in froſty, or over-wet Weather, they may be cover'd with the Glaſſes: If theſe Precautions are uſed, in three or four Years Time the Plants will be fit to tranſplant into the full Ground; you ſhould therefore contrive to plant them in a light ſandy Soil, and a Situation that is ſcreen'd from the North-Eaſt Winds, obſerving to ſhake them out of the Pots with all the Earth to their Roots: This ſhould be perform'd in *April* or *May*, always chuſing a moiſt Seaſon; and when you have planted them, lay a little Mulch upon the Surface of the Ground round about their Roots, to prevent the Sun and Wind from entring the Ground ſo as to dry the Fibres of the Roots, giving them ſome Water to ſettle the Earth to their Roots, and repeating the ſame once a Week if the Weather ſhould be dry; and it will be proper to add a little freſh Mulch about theſe Trees in *October*, to keep the Froſt from penetrating to their Roots: This may be repeated the three firſt Winters after planting out, after which

Time they will have taken ſufficient Root in the Ground, ſo as to be able to endure our Cold very well; and it is by the Neglect of this at firſt that many young Trees miſcarry in Winter at their firſt planting Abroad.

Theſe Trees are, at preſent, very rare, and only to be found in ſome curious old Collections; their Seeds having not been brought into *England* of late Years, there are no young Plants to be met with, tho' this Tree will take by Layers; but they will never thrive ſo well as thoſe rais'd from Seeds, and they are commonly two Years before they ſtrike Root.

The Wood of this Tree is of great Uſe in the *Levant*, where they grow to be large Timber, and is by many thought to be the *Shittim Wood* mention'd in the Scripture, of which many of the Ornaments to the famous *Temple* of *Solomon* were made: It is accounted excellent Wood for Carving, as alſo for many Sorts of Utenſils, and is thought to be equal to almoſt any Sort of Timber for Durableneſs.

CEIBA, Silk Cotton-tree, *vulgo*.

The *Characters* are;

It hath a roſaceous Flower, conſiſting of ſeveral Leaves placed in a circular Order; from whoſe Calyx ariſes the Pointal, which afterwards becomes a Fruit ſhaped like a Bottle, divided into five Parts from the Top to the Bottom; in which are contained ſeveral round Seeds wrapped up in a ſoft Down, and faſtened to the five-cornered pyramidal Placenta.

The *Species* are:

1. CEIBA *viticis foliis, caudice aculeato. Plum. Nov. Gen.* The Silk Cotton-tree, with a thorny Stem.
2. CEIBA *viticis foliis, caudice glabro. Plum. Nov. Gen.* The Silk Cotton-tree, with a ſmooth Stem.

Theſe two Trees grow very plentifully both in the *Eaſt* and *Weſt Indies*, where they arrive to a prodigious Magnitude: the Inhabitants of the *Weſt Indies* hollow the Trunks of theſe Trees for the making of their *Canoes*, for which they are chiefly valued. It is reported, that in the Iſland of *Cuba*, in *Columbus*'s firſt Voyage, was ſeen a *Canoe* made of a hollowed Trunk of one of theſe Trees, which was ninety-five Palms long, and capable of containing one hundred and fifty Men. And ſome modern Writers have affirmed, that there are Trees now growing in the *Weſt Indies* ſo large, as ſcarcely to be fathomed by ſixteen Men, and ſo high, that an Arrow can ſcarcely be ſhot to their Tops.

The Wool of theſe Trees is of a dark Colour, and too ſhort to ſpin; ſo that it is little valued: but ſometimes the Inhabitants ſtuff Beds and Pillows with it, tho' it is accounted unwholſome to lie upon. The Inhabitants of the *Weſt Indies* call this *Silk-cotton*; but the ancient *American* Name for this Plant being *Ceiba*, Father *Plumier* hath continued it under that Name, and conſtituted a Genus of it.

Theſe Plants are preſerved in ſome curious Gardens in *Europe*, where they thrive very well, if they are placed in a Bark-ſtove; but as they are Trees of a large Growth, ſo it can hardly be expected to ſee either Fruit or Flowers from them in *England*, ſince they grow to a great Magnitude, before they produce either in their own Country.

Theſe Plants may be raiſed from Seeds, which are eaſily obtained from the *Weſt Indies*; they muſt be ſown on a Hot-bed early in the Spring; and when the Plants are come up, they muſt be each tranſplanted into a ſmall Pot, filled with freſh light Earth, and plunged into a Hot-bed of Tanners-bark, obſerving to water and ſhade them, until they have taken Root; after which they muſt have free Air let into the Hot-bed, in proportion to the Warmth of the Seaſon; for if the Glaſſes are kept too cloſe, the Plants will draw up too weak. They muſt alſo be frequently refreſhed with Water; for they perſpire pretty freely, eſpecially in hot Weather. In a Month or five Weeks Time, theſe ſmall Pots will be filled with the Roots of the Plants: therefore you muſt ſhake the Plants out of them; and after having pared off the outſide Roots, they muſt be put into Pots a Size larger, and plunged again into the Hot-bed, obſerving to manage them as was before directed. When the Plants are grown too tall to remain in the Hot-bed, they muſt be removed into the Bark-ſtove; where, during the Summer Seaſon, they ſhould have a large Share of freſh Air; but in Winter they muſt be kept pretty cloſe: and as the Plants increaſe in Magnitude, ſo they ſhould be ſhifted into larger Pots, that their Roots may have Room to extend. If theſe Rules be duly obſerved, the Plants will, in two or three Years, arrive to the Height of ten or twelve Feet, and be proportionably ſtrong; and being placed among other Plants, which require the ſame Degree of Heat, they add to the Variety.

There are ſome other Sorts of this Tree in the *Spaniſh* Settlements in *America*; and I have raiſed one Sort, which came from *Siam*, whoſe Leaves reſembled thoſe of Marſhmallow, but the Down and Seeds were exactly the ſame as of the common Sorts. Thoſe Pods which I received from *Panama*, were of a different Figure from the common Sorts, as was the Down alſo; for that was in one of a purple Colour, and the other was of a dark Red. The Down of both theſe Sorts are, by the Inhabitants of thoſe Countries, wrought into Garments, and retain their original Colour, ſo that they are never dyed.

CELASTRUS, the Staff-tree, is a Sort of *Alaternus*.

CELERY or **SALARY**, *vulgo*.

This is by the Botaniſts rang'd under the Article of *Apium*, to which I refer the Reader for its Characters.

There are two Sorts of this Plant cultivated in the *Engliſh* Gardens, for Kitchen Uſe, which are,

1. APIUM *dulce, Celeri Italorum. H. R. Par.* Italian Celeri.
2. APIUM *dulce degener, radice rapacea. Jeſſieu.* Celeriack, *vulgo*.

The Seeds of this Plant ſhould be ſown at two different Seaſons, the better to continue it for Uſe through the whole Seaſon without running up to Seed. The firſt Sowing ſhould be in the Beginning of *March*, which ought to be in an open Spot of light Earth, where it may enjoy the Benefit of the Sun: But the ſecond Time of Sowing ſhould be the Beginning of *April*, which ought to be in a moiſt Soil; and if expos'd to the Morning Sun only, it will be ſo much the better; but it ſhould not be under the Drip of Trees.

In about three Weeks or a Month's time after Sowing, the Seed will come up, when you muſt carefully clear it from Weeds; and if the Seaſon prove dry, you muſt frequently water it; and in about a Month or five Weeks after it is up, the Plants will be fit to tranſplant; you muſt therefore prepare ſome Beds of moiſt rich Earth, in which you ſhould prick theſe young Plants, at about three Inches ſquare, that they may grow ſtrong: You muſt alſo obſerve, in drawing theſe Plants out of the Seed-Beds, to thin them where they grow too thick, leaving the ſmall Plants to get more Strength before they are tranſplanted, by which Means one and the ſame Seed-Bed will afford three different Plantings, which will accordingly ſucceed each other for Uſe.

You muſt obſerve, if the Seaſon proves dry, to keep it diligently water'd after 'tis tranſplanted, as alſo to clear the Seed-Beds from Weeds; and after every drawing, keep them duly water'd, to encourage the ſmall Plants left therein.

The Middle of *June* ſome of the Plants of the firſt Sowing will be fit to tranſplant for Blanching, which, if poſſible, ſhould be put into a moiſt, rich, light Soil, upon which this firſt planted *Celery* will often grow to be twenty Inches long in the clean blanch'd Parts, which upon a poor or dry Soil ſeldom riſes to be ten Inches.

The Manner of tranſplanting it is as follows; After having clear'd the Ground of Weeds, you muſt dig a Trench by a Line about ten Inches wide, and eight or nine Inches deep, looſening the Earth in the Bottom, and laying it level; and the Earth that comes out of the Trench ſhould be equally laid on each Side the Trench, to be ready to draw in again to earth the *Celery* as it advances in Height: Theſe Trenches ſhould be made at three Feet Diſtance from each other; then plant your Plants in the Middle of the Trench, at about ſix Inches Diſtance in one ſtrait Row, having cut off the Tops of the long Leaves, as alſo trimm'd their Roots, obſerving to cloſe the Earth well to their Roots, and to water them plentifully until they have taken freſh Root; after which time it will be needleſs, except in dry Soils, or very dry Seaſons: As theſe Plants advance in Height, ſo you muſt obſerve to draw the Earth on each Side cloſe to them, being careful not to bury their Hearts, nor ever to do it but in dry Weather, otherwiſe the Plants will rot.

When your Plants have advanc'd a conſiderable Height above the Trenches, and all the Earth which was laid on the Sides thereof, hath been employ'd in earthing them up; you muſt then make uſe of a Spade to dig up the Earth between the Trenches, which muſt alſo be made uſe of for the ſame Purpoſe, continuing from time to time to earth it up, until it is fit for Uſe.

The firſt of your planting out will, perhaps, be fit for Uſe a little after Midſummer, and ſo this will be ſucceeded by the after Plantations, and, if rightly manag'd, will continue till *April* or *May*; but you ſhould obſerve, after the ſecond or third planting out, to plant the After-crop in a drier Soil, to prevent its being rotted with too much Wet in Winter; and alſo, if the Weather ſhould prove extreme ſharp, you will do well to cover your Ridges of *Celery* with ſome Peaſe Haulm, or ſome ſuch light Covering, which will admit the Air to the Plants: for if they are cover'd too cloſe, they will be very ſubject to rot; by this Means you may preſerve your *Celery* in Seaſon a long time; but you muſt remember to take off the Covering whenever the Weather will permit, otherwiſe it will be apt to cauſe the *Celery* to pipe and run to Seed: The *Celery*, when fully blanch'd, will not continue good above three Weeks or a Month before it will rot or pipe; therefore, in order to continue it good, you ſhould have, at leaſt, ſix or ſeven different Seaſons of planting; ſo that if it be only intended to ſupply a Family, there need not be much planted at each Time; but this muſt be proportion'd according to the Quantity requir'd.

The other Sort of *Celery*, which is commonly call'd *Celeriack*, is to be manag'd in the ſame Manner as is directed for the *Italian Celery*, but ſhould not be ſown until the Latter-end of *March*, and is very proper for the two laſt Plantations for blanching, as being much hardier than the *Italian* Sort, and will ſtand until *May* before it begins to pipe, (or run to Seed); by which means you may continue this Plant for uſe almoſt two Months longer than is ordinarily done, and, with ſome Care, it may be continued good thro' the whole Year.

The beſt Method to ſave this Seed, is to make choice of ſome long good Roots of *Celery* that have not been too much blanch'd, and plant them out at about a Foot aſunder in a moiſt Soil, early in the Spring; and when they run up to Seed, keep them ſupported with Stakes, to prevent their being broke down with the Wind: And in *July*, when this Seed begins to be form'd, if the Seaſon ſhould prove very dry, it will be proper to give it a little Water, which will greatly help its producing good Seeds. In *Auguſt* theſe Seeds will be ripe, at which time it ſhould be cut up, in a dry Time, and ſpread upon Cloths in the Sun to dry; then beat out the Seeds, and preſerve it dry in Bags for Uſe.

CELLS of *Plants*, [of *Cellæ*, Lat.] are thoſe Partitions or hollow Places in the Huſks or Pods of Plants in which the Seed is contain'd.

CELTIS, the Lote or Nettle-tree.

The *Characters* are;

The Leaves are ſomewhat like thoſe of the Nettle: *The Flowers conſiſt of five Leaves, which are expanded in Form of a* Roſe, *containing many ſhort* Stamina *(or Threads) in the Boſom: The Fruit grows ſingle in the Boſom of its Leaves, which is a roundiſh Berry.*

The *Species* are;

1. CELTIS *fructu obſcurè purpuraſcente. Tourn.* The dark-purpliſh-fruited Lote or Nettle-Tree.
2. CELTIS *fructu nigricante. Tourn.* The Nettle-Tree with black Fruit.
3. CELTIS *fructu luteo ampliori.* The Nettle-Tree with large yellow Fruit.
4. CELTIS *orientalis, folio ampliore, magno fructu. T. Cor.* The Eaſtern Lote or Nettle-Tree, with larger Leaves and Fruit.
5. CELTIS *orientalis minor, foliis minoribus & craſſioribus, fructu flavo. T. Cor.* Smaller Lote or Nettle-Tree, with ſmaller and thicker Leaves, and yellow Fruit.
6. CELTIS *Americana, folio citri ſubtus aureo, fructu rubro. Plum. American* Lote or Nettle-Tree, with a Citron-leaf, and a red Fruit.

The firſt of theſe Trees was originally brought from *Virginia*, but is found to thrive very well in our Climate; there being ſeveral large Trees of this Kind in the Gardens of curious Planters, but particularly one in the Garden which formerly belong'd to *John Tradeſcant* at *South-Lambeth* near *Vaux-Hall* in *Surry*, and another in the *Phyſick-Garden* at *Chelſea*, both which are large Trees, and the latter produces ripe Fruit annually, from whence ſeveral young Trees have been rais'd. The ſecond Sort, tho' a Native of *Europe*, yet is leſs common in *England* than the former, and only to be ſeen in ſome curious Collections of Trees, particularly in the Gardens of the late Dr. *Uvedale* at *Enfield*, where there is one large Tree remaining.

The third Sort is probably a Native of *America* alſo; this Tree hath been many Years growing in *Devonſhire*, where are ſeveral large ones, which have produced ripe Seeds, from whence the Gardens near *London* were ſupply'd with young Plants.

Theſe are all of them very hardy, enduring the ſevereſt of our Winters in *England* very well, and grow to be large Trees; they may be propagated either from Layers, or by Seeds: The Layers are commonly two Years before they take Root ſufficient for tranſplanting; and if they are not frequently water'd, will rarely take Root. The beſt Time for tranſplanting theſe Trees is in *March*, juſt before they begin to put out, obſerving to mulch their Roots, and water them well until they have taken Root. This Tree ſeems to thrive beſt upon a moiſt Soil, tho' it will grow tolerably well upon almoſt any Soil, when it is well fix'd therein.

The Seeds of this Tree ſhould be ſown in the Spring of the Year, ſoon after they are ripe, which is commonly in *January*, and the Ground kept clear from Weeds, but not ſtir'd; for the Seeds ſeldom appear before the ſecond Spring: Therefore the beſt Method is, to ſow them in Boxes, and manage them as was directed for the *Berry-bearing Cedar*; to which I refer the Reader, to avoid Repetition.

Theſe Trees are very uſeful in forming Clumps, or for planting of Amphitheatres of various Kinds of deciduous Trees; for the Heads of theſe naturally grow very thick and regular, and their Leaf is of a deep pleaſant Green Colour, making a very good Diverſity amongſt other Kinds: And altho' it is none of the earlieſt Trees in putting out in the Spring of the Year, yet it recompenſeth for this Defect, by its long Continuance in the Autumn, retaining its Leaves in perfect Vigour, when few other deciduous Trees have any Leaves left upon them.

The Fruit of this Tree is not ſo tempting with Us, as is ſtory'd it was to the Companions of *Ulyſſes*: But the Wood is reckon'd to be of a very durable Nature, and is commonly us'd to make Pipes, and other Wind-Inſtruments, and its Root is very proper to make Hafts for Knives, and other Tools; and it is reported, that they were held in great Eſteem by the *Romans*, for their incomparable Beauty and Uſe.

The fourth and fifth Sorts were diſcovered by Dr. *Tournefort* in his Travels, who ſent their Fruits to the Royal Garden at *Paris*; where they were raiſed, and have ſince been diſtributed to many curious Gardens in *Europe*. Theſe two Sorts are as hardy as the firſt three, ſo that they will endure the ſharpeſt Winters in the open Air, eſpecially when they have acquired ſufficient Strength; for many of theſe Trees may ſuffer by Cold, when they are very young, tho' afterwards they are capable of reſiſting the ſevereſt Cold of this Country.

The fourth Sort will make large Trees, and are proper to range with the other Sorts; but the fifth never grows very large: This will produce Fruit in a few Years after planting, by which it may eaſily be propagated; for the Plants will generally come up the firſt Year, whereas thoſe of the other Sorts ſeldom appear until the ſecond. Theſe Seeds may be ſown in Pots or Boxes filled with light freſh Earth, early in the Spring, and placed where they may have the Morning Sun. In dry Weather they muſt be conſtantly watered, and they muſt always be kept clear from Weeds. At *Michaelmas* the Pots ſhould be removed under a South Wall; and if the Winter ſhould prove very ſevere, it will be proper to ſcreen the Plants with Glaſſes; otherwiſe, being very young, they may be deſtroyed. The following Spring, juſt before the Plants begin to put out, they ſhould be tranſplanted either into ſmall Pots, or into a Nurſery-bed, obſerving, if the Spring ſhould prove very dry, to water them conſtantly, and lay ſome Mulch about their Roots, to prevent the Sun and Air from penetrating to their Roots; and be careful to clear them from Weeds the following Summer. In this Bed they may remain two Years, in which Time they will have acquired Strength enough to be tranſplanted where they are to remain. The beſt Seaſon for removing of them is juſt before they begin to ſhoot, obſerving to water them in dry Weather, and lay ſome Mulch about their Roots, as was before directed. After the Plants are well rooted, they will require no farther Care, but to keep them clear from Weeds, and prevent their being overſhaded with other Trees.

The ſixth Sort was diſcovered by Father *Plumier* in *America*: This is a tender Plant, and will not live out of a Stove in this Country. It may be propagated by Seeds, which muſt be procured from the *Weſt Indies* (for it hath never produced Fruit in *Europe*): The Seeds ſhould be ſown in Pots filled with light freſh Earth, and plunged into a Hot-bed of Tanners-bark: Theſe Pots muſt be conſtantly watered, and in the middle of the Day, when the Weather is mild, the Glaſſes of the Hot-bed ſhould be raiſed to admit freſh Air, and to let the Steam of the Bed paſs off. When the Plants are come up about two Inches high, they ſhould be each tranſplanted into a ſeparate ſmall Pot, filled with light rich Earth, and plunged again into the Hot-bed, obſerving to ſhade the Glaſſes every Day, until the Plants have taken Root; as alſo to water them duly, as you perceive the Earth to dry. During the Heat of Summer, the Plants muſt have a large Share of freſh Air every Day; but at *Michaelmas* they muſt be removed into the Bark-ſtove, and managed as the Coffee-Trees, and other tender exotic Plants; where they will thrive very well, and having ſtrong ſhining Leaves, will make an agreeable Variety.

CENTAURIUM MAJUS. [This Plant takes its Name of the Centaur *Chiron*, who is ſaid to have been heal'd of the Wound in his Foot thereby. It is alſo call'd *Rhaponticum*; becauſe it is by many thought to be the Purging *Rhaponticum*.] The greater Centaury.

The *Characters* are;

It is one of the Plantæ Capitatæ, *(or, of thoſe Plants whoſe Flowers are collected into a Head, as the* Thiſtle, *&c.) and hath a perennial Root: Their Leaves are without Spines, and are ſaw'd on their Edges: The Cup of the Flower is ſquamoſe, but hath no Spines; the Florets are large and ſpecious.*

The *Species* are;

1. CENTAURIUM *majus, folio helenii incano. Tourn.* Greater Centaury, with hoary Leaves like thoſe of Elecampane.
2. CENTAURIUM *folio cinaræ. Cornut.* Greater Centaury, with Artichoke Leaves.
3. CENTAURIUM *majus Alpinum luteum. C. B.* Greater yellow Centaury of the *Alps*.
4. CENTAURIUM *majus, folio in lacinias plures diviſo. C. B.* Greater Centaury with cut Leaves.
5. CENTAURIUM *majus, alterum laciniatum, purpuraſcente flore. H. R. Par.* Another cut-leav'd Centaury with purpliſh Flowers.
6. CENTAURIUM *majus Orientale erectum glaſti folio, flore luteo. T. Cor.* Greater Eaſtern Centaury with Leaves like Woad, and yellow Flowers.
7. CENTAURIUM *majus Africanum acaulon, cinaræ folio. Jeſſieu.* Greater *African* Centaury without Stalks, and Leaves like the Artichoke.

There are ſeveral other *Species* of this Plant cultivated in ſome of the Botanick Gardens Abroad; but theſe here mention'd are what we have at preſent in the *Engliſh* Gardens.

They are all of them propagated either by ſowing their Seeds, or parting their Roots: The latter of which is moſt commonly practis'd in *England*, (their Seeds ſeldom ripening in our Country.) The beſt Seaſon for this Work is either in *October* or *February*.

When you have a mind to increaſe any of theſe Plants, you ſhould open the Ground about their Roots, and clear them of the Earth: Then, where you find any of the Side Heads, which will part with Roots to them, you ſhould carefully force them off; which when you have done, you muſt lay the Earth up again to the old Plant, ſettling it cloſe with your Hands; and if the Ground is dry, give it a little Water: And having prepar'd a proper Place for the young Plants, which ſhould be in a dry ſandy Soil, and a warm Situation, you may either plant them in Beds, at about a Foot ſquare, or at Diſtances in the Borders of large Gardens, by way of Ornament; which altho' the Flowers have no very great Beauty, yet the regular Growth of the Plants, together with their long Continuance in Flower, render them worthy of a Place in all large Gardens.

The Seaſon for ſowing the Seeds of any of theſe *Species*, is in *March*, in an open Bed of common light Earth; and in *May*, when the Plants are come up, they may be tranſplanted into Nurſery-beds until *Michaelmas*; by which Time they will have gotten Strength enough to tranſplant into any other Parts of the Garden where you deſign them to remain.

The third, ſixth, and ſeventh Sorts are the moſt valuable for a Pleaſure-Garden, as being leſs ſubject to grow rude and ungovernable; and their Flowers are of a long Duration. The third Sort is the largeſt of the three, and ſhould be planted in the Middle of large Borders, where they will look very handſome.

The fourth Sort is uſed in Medicine, and therefore deſerves to be cultivated in Phyſick-Gardens: Nor is it unpleaſant in any Garden. The firſt and ſecond Sorts may be admitted for a Variety in large Gardens, to fill empty Borders, where the Difference of their Leaves and Flowers will appear very well amongſt Plants of larger Growth. Theſe Plants begin to produce their Flowers in *June*, and continue moſt part of *July*, but very rarely produce ripe Seeds in this Country.

CENTAURIUM MINUS. [This is call'd *Fel Terræ*, becauſe of its great Bitterneſs.] Leſſer Centaury.

The *Characters* are;

The Leaves grow by Pairs, oppoſite to each other; the Flower conſiſts of one Leaf, is Funnel-ſhap'd, and divided into five acute Segments; theſe grow on the Tops of the Stalks in Cluſters; the Seed-veſſel is of a cylindrical Form, and is divided into two Cells, in which are contain'd many ſmall Seeds.

The *Species* are;

1. CENTAURIUM *minus. C. B.* Common leſſer Centaury.
2. CENTAURIUM *minus, flore albo. H. Eyſt.* Leſſer Centaury with white Flowers.
3. CENTAURIUM *luteum perfoliatum. C. B.* Leſſer yellow Centaury, with Leaves ſurrounding the Stalks.
4. CENTAURIUM *minus maritimum Americanum, amplo flore cœruleo. Plum. Cat. American* Sea leſſer Centaury, with a large blue Flower.

The firſt three Plants grow wild in *England*: The firſt is commonly found growing upon dry arable Land, chiefly amongſt Corn. The ſecond is a Variety of the firſt, from which it only differs in the Colour of the Flower: This is ſometimes found with the firſt. The third Sort grows commonly upon chalky Hills in divers Parts of *England*: But neither of theſe Kinds care to grow in a Garden. The only Method that can be taken to cultivate theſe, is to ſow the Seeds as ſoon as they are ripe, in an open well-expos'd Place, and in a poor dry Soil, with which theſe Plants agree: Nor ſhould the young Plants be remov'd, if they come up, but ſuffer'd to remain in the ſame Places for good. The firſt Sort is us'd in Medicine, and is gather'd in the Fields, and brought to Market for that Purpoſe.

The Seeds of the fourth Plant were ſent from *La Vera Cruz* by the late Dr. *William Houſtoun*, who found this Plant in great Plenty upon low ſwampy Grounds, where the Water ſtagnated, at a great Diſtance from the Sea, in the Country about *Vera Cruz*.

This Plant may be propagated by Seeds, which ſhould be ſown early in the Spring on a moderate Hot-bed; and when the Plants are come up, and are ſtrong enough to tranſplant, they ſhould be each put into a ſeparate ſmall Pot filled with light freſh Earth, and placed into a Hot-bed of Tanners-bark, obſerving to ſcreen them from the Sun, until they have taken new Root; after which Time they muſt have a large Share of freſh Air in warm Weather, and they ſhould be frequently refreſhed with Water. With this Management the Plants will produce their beautiful blue Flowers in Autumn; and, if they are removed into the Bark-ſtove, may be preſerved thro' the Winter; ſo that the following Year there may be Hopes of their producing ripe Seeps, whereby the Plant may be preſerved; for it ſeldom continues, after it has perfected Seeds.

CENTINODIUM, is Knot-graſs.

CEPA, the Onion.

The *Characters* are;

It hath an orbicular, coated, bulboſe Root; the Leaves are hollow or pipy; the Stalk is alſo hollow, and ſwells out in the Middle; the Flowers which conſiſt of ſix Leaves, are collected into a ſpherical Head, or Corymbus; the Style of the Flower becomes a roundiſh Fruit, which is divided into three Cells, containing roundiſh Seeds.

The *Species* are;

1. CEPA *oblonga. C. B.* The *Straſburgh* Onion, *vulgo.*
2. CEPA *vulgaris, floribus & tunicis purpuraſcentibus. C. B.* The red *Spaniſh* Onion, *vulgo.*
3. CEPA *vulgaris, floribus & tunicis candidis. C. B.* The white *Spaniſh* Onion, *vulgo.*
4. CEPA *Aſcalonica Matthioli. Boerh. Ind.* The Scallion or Eſcallion.
5. CEPA *ſectilis juncifolia perennis. M. H.* Cives.
6. CEPA *ſectilis major perennis. Welſh* Onion, *vulgo.*
7. CEPA *fiſſilis Matthioli. Lugd.* Ciboule.

There are ſeveral other Sorts of *Onions* of leſſer Note, which are preſerv'd in the Gardens of curious Botaniſts, ſome of which grow wild in *England*: But theſe above-mention'd are the Sorts which are chiefly cultivated for the Kitchen Uſe. The three Sorts firſt mention'd are propagated for Winter Uſe, their Roots being preſerved dry during that Seaſon. Of theſe I ſhall firſt treat.

Theſe three Sorts of *Onions* are propagated by Seeds, which ſhould be ſown at the latter End of *February*, or the Beginning of *March*, in good rich ſandy Ground (but not too thick; the common Quantity of Seed allow'd to ſow an Acre of Ground being eight Pounds) in about a Month or ſix Weeks after ſowing, the *Onions* will be up forward enough to hough; at which

Time (chuſing dry Weather) you ſhould with a ſmall Hough, about two Inches and an half broad, cut up lightly all the Weeds from amongſt the *Onions*; as alſo cutting out the *Onions*, where they grow too cloſe in Bunches, leaving them at this firſt houghing two Inches apart: This, if well perform'd, and in a dry Seaſon, will preſerve the Spot clear of Weeds, at leaſt a Month, at which Time you muſt hough them over a ſecond Time, cutting up all the Weeds, as before, and alſo cutting out the *Onions* to a larger Diſtance, leaving them this Time three Inches aſunder. This alſo, if well perform'd, will preſerve the Ground clean a Month longer, when you muſt hough them over the third and laſt Time.

You muſt now carefully cut up all Weeds, and ſingle out the *Onions* to near four Inches ſquare; by which means they will grow much larger than if left too cloſe. This Time of Houghing, if the Weather proves dry, and it was well perform'd, will keep the Ground clean until the *Onions* are fit to pull up: But if the Weather ſhould prove moiſt, and any of the Weeds ſhould take Root again, you ſhould, about a Fortnight or three Weeks after, go over the Spot, and draw out all the large Weeds with your Hands; for the *Onions* having now begun to bulb, they ſhould not be diſturb'd with a Hough.

Toward the Middle or Latter-end of *July* your *Onions* will have arriv'd to their full Growth, which may be known by their Blades falling to the Ground and ſhrinking; you ſhould therefore, before their Necks or Blades are wither'd off, draw them out of the Ground, cropping off the extreme Part of the Blade, and lay them abroad upon a dry Spot of Ground to dry, obſerving to turn them over every other Day, at leaſt, to prevent their ſtriking freſh Root into the Ground; which they will ſuddenly do, eſpecially in moiſt Weather.

In about a Fortnight's Time your *Onions* will be dry enough to houſe, which muſt be perform'd in perfect dry Weather: In doing of this, you muſt carefully rub off all the Earth, and be ſure to mix no faulty ones amongſt them, which will in a ſhort time decay, and ſpoil all thoſe that lie near them; nor ſhould you lay them too thick in the Houſe, which would occaſion their ſweating, and thereby rot them: Theſe ſhould not be put in a lower Room, or Ground-floor, but in a Loft or Garret; and the cloſer they are kept from the Air the better they will keep: You ſhould at leaſt once a Month look over them to ſee if any of them are decay'd; which if you find, muſt be immediately taken away, otherwiſe they will infect all that lie near them.

The beſt *Onions* for keeping are the *Strasburgh* Kind, which is an oval-ſhap'd Bulb; but this ſeldom grows ſo large as the *Spaniſh*, which is flatter: The white Sort is eſteem'd the ſweeteſt, but theſe Varieties are not laſting; for if you ſave Seeds of white *Onions* only, you will have a Mixture of the red ones amongſt them; nor will the *Strasburgh Onion* keep long to its Kind, but will by degrees grow flatter, as do the large *Portugal Onions*, when planted in our Climate, which, in a Year or two, will be ſo far degenerated as not to be known they were from that Race.

But, in order to preſerve Seeds, you muſt in the Spring make Choice of ſome of the firmeſt, largeſt, and oval-ſhap'd *Onions*, (in Quantity proportionable to the Seed you intend to ſave) and having prepar'd a Piece of good Ground, (which ſhould be well dug, and laid out in Beds about three Feet wide) in the Beginning of *March* you muſt plant your *Onions*, in the following manner: Having ſtrain'd a Line about four Inches within the Side of the Bed, you muſt with a Spade, throw out an Opening about ſix Inches deep the Length of the Bed, into which you ſhould place the *Onions*, with their Roots downward, at about ſix Inches Diſtance from each other; then with a Rake draw the Earth into the Opening again to cover the Bulbs; then proceed to remove the Line again about ten Inches or a Foot farther back, where you muſt make an Opening as before, and ſo again, till the Whole is finiſh'd, ſo that you will have four Rows in each Bed, between which you muſt allow a Space of two Feet for an Alley to go amongſt them to clear them from Weeds, *&c.* In a Month's Time their Leaves will appear above-ground, and many of the Roots will produce three or four Stalks each, you muſt therefore keep them diligently clear'd from Weeds; and about the Beginning of *June*, when the Heads of the Seed begin to appear upon the Tops of the Stalks, you muſt provide a parcel of Stakes about four Feet long, which ſhould be drove into the Ground, in the Rows of *Onions*, at about ſix Feet apart, to which you ſhould faſten ſome Packthread, or ſmall Cord, which ſhould be run on each Side the Stems of the *Onions*, a little below their Heads, to ſupport them from breaking down with the Wind and Rain.

About the Beginning of *Auguſt* the *Onion*-Seed will be ripe, which may be known by its changing brown, and the Cells in which the Seeds are contain'd opening, ſo that if it be not cut in a ſhort time the Seeds will fall to the Ground: When you cut off the Heads, they ſhould be ſpread abroad upon coarſe Cloths in the Sun, obſerving to take it in under Shelter in the Night, as alſo in wet Weather; and when the Heads are quite dry, you muſt beat out the Seeds, which are very eaſily diſcharg'd from their Cells; then having clear'd it from all the Husk, *&c.* after having expos'd it one Day to the Sun to dry, you muſt put it up in Bags to preſerve it for Uſe.

The *Scallion* or *Eſcallion*, is a Sort of *Onion* which never forms any Bulbs at the Roots, and is chiefly uſed in the Spring for green *Onions*, before the other Sorts ſown in *July* are big enough; but this ſort of *Onion*, how much ſoever in uſe formerly, is now ſo ſcarce as to be known to few People, and is rarely to be met with except in curious Botanick Gardens: The Gardeners near *London* ſubſtitute another Sort for this, which are thoſe *Onions* which decay and ſprout in the Houſe: Theſe they plant in a Bed early in the Spring, which in a ſhort Time will grow to be large enough for Uſe: When they draw them up, and after pulling off all the old outer Coat of the Root, they tie them up in Bunches, and ſell them in the Market for *Scallions*.

This true *Scallion* is eaſily propagated by parting the Roots, either in *Spring* or *Autumn*, but the latter Seaſon is preferable, becauſe of their being render'd more fit for Uſe in the *Spring*: Theſe Roots ſhould be planted three or four together in a Hole, at about ſix Inches Diſtance every Way, in Beds or Borders three Feet wide, which in a ſhort time will multiply exceedingly, and will grow upon almoſt any Soil, and in any Situation; and their being ſo hardy as to reſiſt the ſevereſt of our Winters, and being green and fit for Uſe ſo early in the *Spring*, renders them worthy of a Place in all good Kitchen Gardens.

The *Cives* are a very ſmall Sort of *Onion*, which never produces any Bulbs, nor ſeldom grows above ſix Inches high in the Blade, which is very ſmall and ſlender, and grows in Bunches like the former: This was formerly in great Requeſt for *Sallads* in the Spring, as being ſomewhat milder than thoſe *Onions* which had ſtood through the Winter: Theſe are propagated by parting their Roots like the former, and are alſo very hardy, and will be fit for Uſe early in the Spring.

The *Welſh Onions* are only propagated for Spring Uſe alſo: Theſe never make any Bulb, and are therefore only fit to be us'd green for *Sallads*, *&c.* They are ſown about the End of *July*, in Beds of about three Feet and a half wide, leaving Alleys of two Feet broad to go between the Beds to clean them, and in a Fortnight's Time they will appear above-ground, and muſt be carefully clear'd from Weeds; towards the Middle of *October*, their Blades will die away, ſo that the whole Spot will ſeem to be naked, which hath led many People to dig up the Ground again, ſuppoſing the Crop totally loſt; whereas if they are let ſtand undiſturb'd, they will come up again very ſtrong in *January*, and from that time grow very vigorouſly, reſiſting all Weathers, and by *March* will be fit to draw for young *Onions*, and are, in the Markets, more valu'd than any other Sort at that Seaſon; for they are extremely green and fine, tho' they are much ſtronger than the common *Onion* in Taſte, approaching nearer to *Garlick*, which hath occaſion'd their being leſs eſteem'd for the Table: But as no Winter, however ſo hard, will hurt them, ſo it is proper to have a few of them to ſupply the Table, in caſe the common Sort ſhould be deſtroy'd by Froſts.

The Roots of theſe *Onions*, if planted out at ſix or eight Inches Diſtance in *March*, will produce ripe Seeds in *Autumn*, but 'twill be in ſmall Quantities the firſt Year; therefore the ſame Roots ſhould remain unremov'd, which the ſecond and third Year will produce many Stems, and afford a good Supply of Seeds: Theſe Roots will abide many Years good, but ſhould be tranſplanted and parted every ſecond or third Year, which will cauſe them to produce ſtrong Seeds.

CERASUS; [ſo call'd of *Ceraſus*, a City of *Pontus*, which *Lucullus* having deſtroy'd, he carry'd the *Cherry-Tree* from thence to *Rome*, and call'd it *Ceraſus*, after the Name of the City.] The Cherry-Tree.

The *Characters* are;

It hath large ſhining Leaves; the Fruit grows on long Pedicles (or Footſtalks) and is roundiſh or Heart-ſhap'd; the Stone is ſhort, tumid, and roundiſh.

The *Species* are;

1. CERASUS *ſativa, fructu rotundo, rubro & acido. Tourn.* The common Red or Garden Cherry.

2. CERASUS *ſativa, fructu majori. Tourn.* Large *Spaniſh* Cherry.

3. CERASUS *major, fructu magno cordato rubro.* The Red Heart Cherry.

4. CERASUS *major, fructu magno cordato albo.* The White Heart Cherry.
5. CERASUS *major, fructu magno, cordato ſanguineo.* The Bleeding Heart Cherry.
6. CERASUS *major, fructu cordato nigro.* The Black Heart Cherry.
7. CERASUS *Maialis, fructu duro ſubdulci. Tourn.* The *May* Cherry.
8. CERASUS *major, ac ſylveſtris, fructu ſubdulcis, nigro colore inficiente. C. B.* The Black Cherry or Mazzard.
9. CERASUS *fructu magno rubro turbinato. Tourn.* The Arch-duke Cherry.
10. CERASUS *Sicula, fructu caſtanei coloris. Tourn.* The Yellow *Spaniſh* Cherry, *vulgo.*
11. CERASUS *uno pediculo, plura ferens. J. B.* The *Flanders* Cluſter Cherry.
12. CERASUS *fructu incarnato.* The Carnation Cherry.
13. CERASUS *ſativa, fructu orbiculato nigerrimo micante. Tourn.* The large Black Cherry.
14. CERASUS *racemoſa, ſylveſtris, fructu non eduli. C. B.* The Bird Cherry.
15. CERASUS *racemoſa, ſylveſtris, fructu non eduli rubro. H. R. Par.* The Red Bird or Corniſh Cherry.
16. CERASUS *hortenſis, flore roſeo. C. B.* The Largeſt Double-flower'd Cherry.
17. CERASUS *hortenſis, pleno flore. C. B.* The Double-flower'd Cherry.
18. CERASUS *ſylveſtris, fructu rubro. J. B.* Common Wild Cherry.
19. CERASUS *ſylveſtris ſeptentrionalis Anglica, fructu rubro parvo ſerotino. Raii Hiſt.* The Wild Northern *Engliſh* Cherry, with late ripe Fruit.
20. CERASUS *ſylveſtris, amara, mahaleb putata. J. B.* The Rock or Perſum'd Cherry.
21. CERASUS *hortenſis, foliis eleganter variegatis.* The Cherry Tree with ſtrip'd Leaves.

There are many other Sorts of Cherries cultivated in curious Fruit-Gardens; as, the Amber Cherry, Lukeward, Corone, Gaſcoigne, Morello, &c.

All the Sorts of Cherries which are uſually cultivated in Fruit-Gardens, are propagated by Budding or Grafting the ſeveral Kinds, into Stocks of the Black, or Wild Red Cherries, which are ſtrong Shooters, and of a longer Duration than any of the Garden Kinds. The Stones of theſe two Kinds are ſown in Beds of light ſandy Earth in Autumn, (or are preſerv'd in Sand till Spring, and then ſow'd): When theſe Stocks ariſe, they muſt be carefully weeded; and if in dry Weather you refreſh them with Water, it will greatly promote their Growth. Theſe young Stocks ſhould remain in theſe Nurſery Beds till the ſecond Autumn after ſowing, at which Time you ſhould prepare an open Spot of good freſh Earth, which ſhould be well work'd: But if the Soil is freſh, you'll need no Dung. In this Ground in *October* you ſhould plant out the young Stocks at three Feet Diſtance, Row from Row, and about ten Inches aſunder in the Rows; being careful, in taking them up from their Seed-beds, to looſen their Roots well with a Spade, to prevent their breaking; as alſo to prune their Roots: And if they are inclinable to root downwards, you ſhould ſharpen the Tap-root, to cauſe it to put out lateral Roots: But do not prune their Tops; for this is what by no means they will endure.

The ſecond Year after planting out, if they take to growing well, they will be fit to bud, if they are intended for Dwarfs: but if they are for Standards, they will not be tall enough until the fourth Year; for they ſhould be budded or grafted near ſix Feet from the Ground; for otherwiſe the Graft will not advance much in Height, ſo that it will be impoſſible to make a good Tree from ſuch as are grafted low.

The uſual Way with the Nurſery-Gardeners, is to bud their Stocks in Summer: And ſuch of them as miſcarry, they graft the ſucceeding Spring. (The Manner of theſe Operations will be deſcribed under their proper Heads.) Thoſe Trees where the Buds have taken, muſt be headed off in the Beginning of *March*, about ſix Inches above the Bud: And when the Bud hath ſhot in Summer, if you fear its being blown out by the Winds, you may faſten it up with ſome Baſs, or ſuch ſoft Tying, to that Part of the Stock which was left above the Bud. The Autumn following theſe Trees will be fit to remove. But if your Ground is not ready to receive them, they may remain two Years before they are tranſplanted: In the doing of which, you muſt obſerve not to head them, as is by many practis'd: for this, very often, is immediate Death to them: but if they ſurvive it, they ſeldom recover this Amputation in five or ſix Years.

If theſe Trees are intended for a Wall, I would adviſe the planting Dwarfs between the Standards; ſo that while the Dwarfs are filling the Bottom of the Walls, the Standards will cover the Tops, and will produce a great deal of Fruit: But theſe, as the Dwarfs ariſe to fill the Walls, muſt be cut away, to make room for them: And when the Dwarf-trees do cover the Walls, the Standards ſhould be intirely taken away. But I would adviſe, never to plant *Standard-Cherries* over other Fruit; for there is no other Sort of Fruit that will proſper well under the Drip of *Cherries*.

When theſe Trees are taken up from the Nurſery, their Roots muſt be ſhortned, and all the bruiſed Parts cut off, as alſo all the ſmall Fibres, which would dry, grow mouldy, and be a great Prejudice to the new Fibres in their coming forth; you muſt alſo cut off the dead Part of the Stock which was left above the Bud, cloſe down to the back-part of it, that the Stock may be cover'd. If theſe Trees are deſign'd for a Wall, obſerve to place the Bud directly from the Wall, that the back-part of the Stock that was cut, may be hid from Sight. The Soil that *Cherries* thrive beſt in, is a freſh Hazel Loam: But if the Soil is a dry Gravel, they will not live many Years, and will be perpetually blighted in the Spring.

The Sorts commonly planted againſt Walls, are the *Early-May*, and *May-Duke*, which ſhould have a South-Wall. The *Hearts* and *common Duke* will do upon a Weſt-Wall; and the *Morello* on a North-Wall, which laſt is chiefly planted for preſerving. The *Hearts* are all of them ill Bearers; for which Reaſon they are ſeldom planted againſt Walls: But I am apt to believe, if they were grafted upon the *Bird-Cherry*, and manag'd properly, that Defect might be remedy'd; for this Stock (as I am inform'd) will render *Cherries* very fruitful; and having the ſame Effect on *Cherries*, as the *Paradiſe* Stock hath on *Apples*, they may be kept in leſs Compaſs, which is an Experiment well worth the Trial.

Your Trees, if planted againſt a Wall, ſhould be placed fourteen Feet aſunder, with a Standard-tree between each Dwarf: This will be found a reaſonable Diſtance, when we conſider that *Cherry-Trees* will not extend themſelves ſo far as *Apricocks*, and many other Sorts of Fruit.

In pruning theſe Sorts of Fruits, you ſhould never ſhorten their Shoots; for the moſt part of them produce their Fruit-buds at their extreme Part, which, when ſhortned, are cut off: Their Branches ſhould be therefore train'd in at full Length horizontally, obſerving in *May*, where there is a Vacancy in the Wall, to ſtop ſome ſtrong adjoining Branches, which will occaſion its putting out two or more Shoots; by which Means, at that Seaſon of the Year, you may always get a Supply of Wood for covering the Wall: And at the ſame time ſhould all fore-right Shoots be diſplac'd by the Hand; for if they are ſuffer'd to grow till Winter, they will not only deprive the bearing Branches of their proper Supply of Nouriſhment; but, when they are cut out, it occaſions the Tree to Gum in that Part; (for *Cherries* bear the Knife the worſt of any Sort of Fruit-Trees): but be careful not to rub off the *Fides* or Spurs, which are produc'd upon the two and three Years old Wood; for it is upon theſe that the greateſt Part of the Fruit are produc'd; which *Fides* will continue fruitful for ſeveral Years. And it is for want of duly obſerving this Caution, that *Cherry-Trees* are often ſeen ſo unfruitful, eſpecially the *Morello*, which, the more it is cut, the weaker it ſhoots; and at laſt, by frequent pruning, I have known a whole Wall of them deſtroy'd; which, if they had been ſuffer'd to grow without any pruning, might probably have liv'd many Years, and produc'd large Quantities of Fruit.

Cherry-Trees are alſo planted for Orchards in many Parts of *England*, particularly in *Kent*, where there are large Plantations of theſe Trees: The uſual Diſtance allow'd for their ſtanding, is forty Feet ſquare, at which Space they are leſs ſubject to Blight, than when they are cloſer planted; and the Ground may be till'd between them almoſt as well as if it were intirely clear, eſpecially while the Trees are young; and the often ſtirring the Ground, provided you do not diſturb their Roots, will greatly help the Trees; but when they are grown ſo big as to overſhadow the Ground, the Drip of their Leaves will ſuffer very few Things to thrive under them. Theſe Standard Trees ſhould be planted in a Situation defended as much as poſſible from the ſtrong Weſterly Winds, which are very apt to break their tender Branches; this occaſions their Gumming, and is very prejudicial to them.

The Sorts beſt approved for an Orchard, are the *Common Red* or *Kentiſh Cherry*, the *Duke*, and *Lukeward*, all which are plentiful Bearers. But Orchards of theſe Trees are now ſcarcely worth planting, except where Land is very cheap; for the Uncertainty of their Bearing, with the Trouble in gathering the Fruit, together with the ſmall Price it commonly yields, have occaſion'd the deſtroying many Orchards of this Fruit in *Kent*, within a few Years paſt.

This Fruit was brought out of *Pontus*, at the Time of the *Mithridatick* Victory, by *Lucullus*, in the Year of the City 680, and were brought into *Britain* about 120 Years afterwards, which was *An. Dom.* 55, and were ſoon after ſpread through moſt Parts of *Europe*; it being generally eſteem'd for its Earlineſs, as being one of the firſt of the Tree-Fruit that appears to welcome in the approaching Fruit-ſeaſon.

This Sort of Fruit hath been by many People grafted upon the *Laurel*, to which it is a *Congener*: But what Effect it hath either in the Growth of the Tree, or its Fruit, I have not been yet able to underſtand; tho' this Practice is as old as *Pliny*, who ſays it gives the Fruit a very pleaſant Bitterneſs.

The two Sorts of *Bird Cherries* are very fine flowering Trees, and are commonly propagated in the Nurſeries, to intermix with *Lilac's*, *Laburnum's*, and other flowering Trees of larger Growth, where, by their Variety, they greatly diverſify the Proſpect. Theſe are alſo, by ſome, us'd for Stocks, to bud and graft the moſt generous Kinds of *Cherries* on; by which means they are render'd more fruitful, and of leſſer Growth: Theſe two Sorts are propagated by laying down their tender Branches in Autumn, which in one Year's time will have taken Root, and may be remov'd into a Nurſery, for any of the above-mention'd Purpoſes.

The two Sorts of *Double-flowering Cherries* are alſo propagated for the Beauty of their Flowers, which, of the very double Kind, are extremely fine, the Flowers being as double and large as a *Cinnamon-Roſe*, and theſe being produced in large Bunches on every Part of the Tree, renders it one of the moſt beautiful Trees of the Spring. The other Sort, which is leſs double, will often produce ſome Fruit, which the very double Sort doth not; but this Defect is ſufficiently recompens'd in the Beauty of its Flowers. Theſe are propagated by Budding or Grafting them on the *Black* or *Wild Cherry* Stock, and are proper to intermix with the larger Sort of flowering Trees.

The *Wild Northern Cherry* is of no Uſe or Beauty, and is only preſerved by the Curious, in Collections of the different Sorts of Trees; as is alſo the *Machaleb* or *Perfum'd Cherry*, which is a free Shooter, and perhaps may ſerve for Stocks to improve the other Kinds of *Cherries*, as growing well in almoſt any Soil; but there is neither Uſe nor Beauty in the Flowers or Fruit of it. The *Strip'd-Leav'd Cherry* is proper in a Collection of variegated Trees, as adding to the Variety.

CERATIA; *vide* Siliqua Edulis.

CEREFOLIUM: *vide* Chærefolium.

CEREUS. The Torch-Thiſtle.

Theſe are all *American* Plants, where the Fruit are eaten as Figs: They lie in the Way in great Plenty, and being thorny, are injurious to thoſe who paſs among them naked. The eleventh as to its outward Shew, ſeems to be no very rare or curious Plant, but it has a very fine Flower, which beginning to open itſelf about the Evening, falls after Midnight: and hence it is call'd, 'Ελεοφυγὰς, i. e. *ſhunning the Sun.* The tenth Sort bears Figs of a moſt delicate Taſte; it is call'd *Cereus*, becauſe it is, as it were, a kind of *Taper* or *Torch*, which the Servants carry o' Nights before their Maſters.

Not that it is call'd ſo from its Reſemblance to a *Torch*, but becauſe, when theſe Plants have been cut down, and dry'd upon the Ground, they dip them into Oil, and burn them as *Torches*, for which Purpoſe they ſerve very well.

The *Characters* are;

It hath no Leaves; the Stems are thick and ſucculent; are angular and furrow'd, each Angle being arm'd with ſharp Spines, which are produc'd in Cluſters; the Flowers conſiſt of many flat Leaves, which expand themſelves ſomewhat like a Marygold: *In the Centre of the Flower is produc'd a great Number of Stamina (or Threads) which appear very ſpecious; the Fruit, which is fleſhy, ſoft, and like to that of the* Indian Fig, *is produc'd from the Side of the Plant, without any Footſtalk, immediately under the Flower.*

The *Species* are;

1. CEREUS *erectus altiſſimus Syrinamenſis. Par. Bat.* The large upright Torch-Thiſtle from *Surinam*.

2. CEREUS *erectus quadrangulus, coſtis alarum inſtar aſſurgentibus. Boerh. Ind.* The four-corner'd upright Torch-Thiſtle.

3. CEREUS *erectus, fructu rubro non ſpinoſo, lanuginoſus lanugine flaveſcente. Par. Bat.* The upright Torch-Thiſtle, with yellow Down and red Fruit without Spines.

4. CEREUS *erectus craſſiſſimus maxime anguloſus, ſpinis albis pluribis longiſſimis, lanugine flava. Boerh. Ind.* The largeſt upright Torch-Thiſtle, with large Angles and white Spines, having a yellow Down on the Top.

5. CEREUS *erectus gracilis, ſpinoſiſſimus ſpinis flavis, polygonus, lanugine alba palleſcente. Boerh. Ind.* The leſſer upright Torch-Thiſtle, with many Angles and yellow Spines, with a white Down on the Top.

6. CEREUS *erectus gracilior, ſpinoſiſſimus ſpinis albis, polygonus. Boerh. Ind.* The leſſer upright Torch-Thiſtle, with white Spines.

7. CEREUS *altiſſimus, gracilior, fructu extus luteo, intus niveo, ſeminibus nigris pleno. Sloan. Cat.* The leſſer upright Torch-Thiſtle, with Fruit on the Outſide yellow, and white within, and full of black Seeds.

8. CEREUS *maximus, fructu ſpinoſo rubro. Par. Bat.* The greateſt Torch-Thiſtle, with red prickly Fruit.

9. CEREUS *ſcandens minor trigonus articulatus, fructu ſuaviſſimo. Par. Bat.* The leſſer triangular creeping, jointed Torch-Thiſtle, with the ſweeteſt Fruit, *commonly call'd* in *Barbadoes*, the True prickly Pear.

10. CEREUS *criſtatus erectus, foliis triangularibus, profunde canaliculatis. Pluk. Phyt.* The creſted triangular Torch-Thiſtle, with deep Furrows.

11. CEREUS *ſcandens minor polygonus articulatus. Par. Bat.* The leſſer creeping, jointed Torch-Thiſtle, with many Angles.

12. CEREUS *minimus articulatus polygonus ſpinoſus. Boerh. Ind.* The leaſt prickly jointed Torch-Thiſtle with many Angles.

The firſt Sort is the hardieſt, as alſo the moſt common in *England* of any of theſe Sorts, and may be preſerv'd in a good Green-houſe without any artificial Heat, provided the Froſt is kept intirely out, and the Plant kept very dry all the Winter, for Wet is the greateſt Enemy to theſe Plants.

The 2d, 3d, 4th, 5th, 6th, 7th and 8th Sorts are ſomewhat tenderer, and will require a little artificial Warmth in very bad Weather; therefore theſe ſhould be plac'd in a Stove, which is kept up to the temperate Heat, mark'd on Mr. *Fowler*'s *Thermometers*: Theſe muſt alſo have very little Water in the Winter Seaſon.

The 9th Sort is, by the Inhabitants of *Barbadoes*, train'd up againſt their Houſes, for the Sake of its Fruit, which is about the Bigneſs of a *Bergamot-Pear*, and of a moſt delicious Flavour. This, with the 10th, 11th and 12th Sorts, are very tender, and require a very warm Stove to preſerve them: Theſe ſhould be plac'd againſt the Walls of the Stove, into which they will inſinuate their Roots, and extend themſelves to a great Length, and with a little Help, in faſtening them to the Wall here and there, may be led up about the Cieling of the Houſe, where they will appear very handſome. And the 11th Sort, when arriv'd to a ſufficient Strength, will produce many exceeding large, beautiful, ſweet-ſcented Flowers; but they are (like all the Flowers of theſe Kinds) of a very ſhort Duration, ſcarcely continuing full blown twelve Hours; nor do the ſame Flowers ever open again, when once clos'd: Theſe Flowers open in the Afternoon, and before the next Morning ſhut up again.

I don't remember to have heard of any of the other Sorts (except the firſt and ſeventh) which have produc'd Flowers in *Europe*; tho' it is to be hop'd, that when they are arriv'd to a ſufficient Strength, they will flower as well as thoſe two; but at preſent, the Plants of the other Sorts are but young, having been in *England* but a few Years. The firſt Sort ſeldom produces its Flowers until arriv'd to a conſiderable Age, unleſs by ſome Accident, which many times occaſions their flowering ſooner than they are commonly inclin'd to. Of this Kind, there was a very large Plant in the *Royal Garden* at *Paris*, which was upward of thirty Feet high, and had produc'd Flowers for ſeveral Years; but by the Severity of the Winter (*Anno* 1728) was deſtroy'd. There was alſo another in the *Phyſick Garden* at *Leyden*, which, in the Year 1727, when I was there, was above twenty Feet high, and had a great Number of Flowers upon it; but I don't know of any in *England* that are above twelve or fourteen Feet high, tho' there have been many which have flower'd within a few Years paſt. The ſeventh Sort has produced ripe Fruit in the *Phyſick Garden* at *Chelſea*, but it was very ill-flavoured, nor have the Flowers much Beauty, being of a whitiſh green Colour.

Theſe are all propagated by Cuttings, ſo that if you intend to increaſe the Number of them, you muſt cut off their Stems, at what Length you pleaſe: Theſe ſhould be laid in a dry Place to heal, at leaſt ten Days or a Fortnight before they are planted; but if they lie three Weeks, it is much the better, and they will be in leſs Danger of miſcarrying.

Theſe Cuttings ſhould be planted in ſmall Pots, fill'd with light ſandy Earth, with a Mixture of Lime-rubbiſh, laying ſome Stones in the Bottom of the Pots to drain off the Moiſture; then place the Pots into a gentle Hot-bed of Tanner's-bark, to facilitate their rooting, giving them once a Week a gentle Watering.

The beſt Seaſon for this Work is in *June* or *July*, that they may have time to root before Winter: Toward the Middle of *Auguſt* you muſt begin to give them Air by Degrees, to harden them againſt Winter, but they ſhould not be wholly expos'd to the open Air or Sun: At the End of *September* they muſt be remov'd into the Stove where they are to abide the Winter: during which Seaſon, you muſt be very careful not to let them have much Water, and always obſerve to place the young Plants, for the firſt Winter, in a little warmer Situation than the older Plants, as being ſomewhat tenderer.

Theſe Plants ſhould always have a dry Situation in Winter; for as they imbibe the greateſt Part of their Nouriſhment from the circumambient Air, ſo if this be too replete with moiſt Particles, it will occaſion their rotting. Theſe Plants ſhould none of them be expos'd abroad, not even in the Midſt of Summer; for great Rains, which often happen at that Seaſon, are very injurious to them: The firſt eight Sorts ſhould be therefore plac'd ſo as to enjoy a free Air in the Summer, but at the ſame time ſcreen'd from Rains and great Dews; it will therefore be much the better Method to ſet them in an open Glaſs-ſtove, where the Windows may be ſet open in good Weather, and ſhut in cold or wet. The other four Sorts muſt not be expos'd too much to the open Air, even in the hotteſt Seaſon, eſpecially if you deſign to have them flower; and in Winter they ſhould be kept very warm, and have no Water given them.

When you have once cut off the Tops of any of theſe Plants, in order to increaſe them, the lower Parts will put forth freſh Shoots from their Angles, which when grown to be eight or nine Inches long, may alſo be taken off to make freſh Plants, and by this means the old Plants will continually afford a ſupply, ſo that you never need cut off above one Plant of a Sort, which you ſhould preſerve for a Breeder.

Theſe Plants being ſucculent, they will bear to be a long time out of the Ground; therefore whoever hath a mind to get any of them from the *Weſt-Indies*, need give no other Inſtructions to their Friends, but to cut them off, and let them lie two or three Days to dry; then put them up in a Box with dry Hay or Straw, to keep them from wounding each other with their Spines; and if they are two or three Months on their Paſſage, they will keep very well, provided no Wet get to them.

CERINTHE; [Κηρινθὴ of Κηρὸς, Gr. *Wax*; becauſe the Bees in the Summer-time, while they are making their Honey-combs, do from this Plant, of which they are great Lovers, extract a Juice wherewith they make their Wax] Honey-wort.

The *Characters* are;

It hath glaucous deep-green Leaves, which are for the moſt part beſet with Prickles; the Flowers are cylindrical, conſiſting of one Leaf, in Shape like thoſe of Comfrey, *and are pendulous; each Flower is ſucceeded by two oblong naked Seeds.*

The *Species* are;

1. Cerinthe *quorundam, major, verſicolore flore. J. B.* The larger Honey-wort, with party-colour'd Flowers.
2. Cerinthe *quorundam, major, ſpinoſo folio, flavo flore. J. B.* The large Honey-wort, with prickly Leaves and yellow Flowers.
3. Cerinthe *quorundam, major, flore ex rubro-purpuraſcente. J. B.* The large Honey-wort, with reddiſh purple Flowers.
4. Cerinthe *quorundam, minor, flavo flore. J. B.* The leſſer Honey-wort, with yellow Flowers.
5. Cerinthe *folio non maculato, viridi. C. B.* Honey-wort, with deep-green Leaves, without Spots.
6. Cerinthe *flore verſicolore, ex albo & rubro. Boerh. Ind.* Honey-wort, with red and white party-colour'd Flowers.
7. Cerinthe *flore verſicolore ex albo & purpureo. Boerh. Ind.* Honey-wort, with purple and white party-colour'd Flowers.

The ſeveral Varieties of this Plant are propagated by Seeds, which ſhould be ſown ſoon after they are ripe, for if they are kept till Spring, the growing Quality of them is often loſt; the Plants are hardy, and if the Seeds are ſown in a warm Situation, they will endure the Winter's Cold very well without Shelter: Theſe *Autumnal* Plants alſo are much ſurer to produce ripe Seeds than thoſe which were ſown in the *Spring*, which are generally late in the Seaſon before they flower, and conſequently, if the *Autumn* ſhould not prove very warm, their Seeds would not be perfected.

Theſe Plants are pretty Varieties for large Borders in Gardens, where, if they are ſuffer'd to drop their Seeds, the Plants will ariſe without any farther Care; ſo that when a Perſon is once furniſh'd with the ſeveral Varieties, he need be at no more Trouble than to allow each of them a reſpective Place, where it may remain, and ſow its ſelf: And with this Culture there is a greater Certainty of preſerving the Sorts than in any other Management; nor will they perhaps be entirely loſt in this Way, if it ſhould happen, that the Seaſon ſhould prevent its maturating the Seed, (as it ſometimes proves); for when great Quantities of the Seeds have ſcatter'd upon the Ground, ſome of them will be buried ſo deep, in ſtirring the Earth, as not to grow the firſt Year; which upon being turn'd up to the Air, the ſucceeding Year, will come up as well as new Seeds.

CETERACH; *vide* Aſplenium.

CHÆROPHYLLUM; χαιρόφυλλον, of χαίρω *to rejoice*; and φύλλον, Gr. a *Leaf*, becauſe the Leaves being drank, do exhilarate and chear melancholy Perſons; it is alſo call'd *Cerefolium*, as though *Ceres*'s Leaves, becauſe this Plant ſerves the Table, where, in old Time, the Goddeſs *Ceres* did preſide.

The *Characters* are;

It is an Umbelliferous Plant, whoſe Leaves are divided into many Segments; the Petals of the Flower are bifid, and heart-ſhap'd, and each Flower is ſucceeded by two long Seeds, which are not furrow'd.

The *Species* are;

1. Chærophyllum *ſativum. C. B.* Garden or manur'd Chervil.
2. Chærophyllum *ſylveſtre, perenne, Cicutæ folio. Tourn.* Wild Perennial Chervil or Cow-weed.

The firſt of theſe *Species* is cultivated in the Kitchen-garden for *Sallads*, &c. The Seeds of this Plant ſhould be ſown in Autumn, ſoon after it is ripe, or very early in the Spring, otherwiſe it very often miſcarries; and as the Plant is annual, if it have a cool ſhady Spot of Ground allotted for it, and be ſuffer'd to ſow its ſelf, it will thrive better than when cultivated by Art.

The ſecond Sort grows wild upon moſt dry Banks and Hedge-ſides near *London*.

CHAMÆCERASUS: of χαμαὶ, *the Ground*; and χέρασος, Gr. *a Cherry-Tree*; as if we ſhould ſay, a *Dwarf-Cherry*] Upright Honey-ſuckle, *vulgo*.

The *Characters* are;

It is a Shrub growing upright to the Height of eight or nine Feet; whoſe Flowers conſiſt of one Leaf, which open towards the Top like two Lips, ſomewhat after the manner of the Honey-ſuckle. Theſe Flowers are ſucceeded by Berries ſomewhat like ſmall Cherries; *two of which are, for the moſt part, produc'd upon one Pedicle.*

The *Species* are;

1. Chamæcerasus *dumetorum, fructu gemino rubro. C. B.* The upright red-berried, or Fly-honeyſuckle, *vulgo*.
2. Chamæcerasus *Alpina, fructu gemino rubro, duobus punctis notato. C. B.* The greater upright red-berried Honey-ſuckle.
3. Chamæcerasus *montana, fructu ſingulari cœruleo. C. B.* The upright blue-berried Honeyſuckle.

Theſe Shrubs are very proper Ornaments for Wilderneſs Quarters, to intermix with others which are nearly of the ſame Growth, where by the Diverſity of their Leaves, and their regular Growth, they appear very well.

They are propagated by laying their tender Branches, which in one Year will have good Roots, and may be ſafely tranſplanted either into Nurſeries, or where they are intended to remain. The beſt Seaſon for this Work is in the Spring, before they begin to ſhoot: They may alſo be increas'd by planting Cuttings in the Autumn, in an Eaſt Border, where they may be defended from the great Heat of the Mid-day Sun, and carefully water'd in dry Weather: But theſe will ſcarcely have Roots fit to bear tranſplanting in leſs than two Years; and the blue-berried Kind is pretty difficult to take Root from Cuttings; therefore that ſhould always be propagated by Layers, if poſſible; which in laying ſhould be ſlit at the Joint, as is done in laying *Carnations*, which will greatly facilitate their ſtriking out Roots.

There are ſome other *Species* of this Shrub in the curious Botanick Gardens abroad, particularly in that admirable Collection of *Trees* and *Shrubs* in the Garden of the learned Dr. *Boerhaave*, near *Leyden* in *Holland*, where, amongſt a great Variety of other uncommon Trees, (perhaps more than in any one Garden in *Europe*, and which have been all collected together at the ſole Expence of the worthy Poſſeſſor) which that curious Gentleman was pleas'd to ſhew me, I obſerv'd two or three Sorts of this Tree which I had never before ſeen.

The firſt and ſecond Sorts are of quicker Growth than the third, and will, in a few Years, riſe to the Height of ſix or ſeven Feet; whereas the third ſeldom riſes above four or five Feet high with us.

CHAMÆCISTUS. *Vide* Helianthemum.

CHAMÆCLEMA; [of χαμαὶ, *low*, and κλῆμα, *to climb*, i. e. *Dwarf-climber*; or rather] *Hedera Terreſtris*, or Ground-Ivy.

The *Characters* are;

The Shoots trail upon the Ground, and emit Roots from almoſt every Joint, which faſten themſelves into the Earth; the Leaves are roundiſh, thick, rough, and are crenated on the Edges; the Helmet of the Flower is roundiſh, bifid, and reflex'd; the Beard (or lower Lip) is trifid, or cut into three Segments; the middle Segment is broad, and bifid; and the Flowers are produc'd at the Joints of the Shoots.

The *Species* are;

1. CHAMÆCLEMA *vulgare. Boerh. Ind.* Common Ground-Ivy, or Gill-go-by-Ground.
2. CHAMÆCLEMA *minus. Boerh. Ind.* Leſſer Ground-Ivy.
3. CHAMÆCLEMA *vulgare, foliis profunde inciſis.* Common Ground-Ivy, with deep-cut Leaves.
4. CHAMÆCLEMA *minus, foliis ex albo variegatis.* The leſſer Ground-Ivy, with variegated Leaves.

The two firſt Sorts grow wild in moſt Parts of *England*, upon the Sides of Banks and Foot-ways, and are promiſcuouſly gather'd by the Herb-women, and brought to the Market for medicinal Uſes. The third Sort is a Variety of the firſt, which for three or four Years held its Difference in the *Phyſick-Garden.* The fourth Sort is a Variety of the ſecond, which conſtantly continues, if it be not planted in too rich a Soil: This is a pretty Variety amongſt other variegated Plants, and increaſes faſt enough by its trailing Branches.

CHAMÆCYPARISSUS. *Vide* Santolina.

CHAMÆDAPHNE. *Vide* Ruſcus.

CHAMÆDRYS; [Χαμαίδρυς, of χαμαὶ, *Dwarf*, and Δρῦς, an *Oak*, i. e. *Dwarf-Oak.*] Germander.

The *Characters* are;

It hath ſmall thick Leaves, which are laciniated ſomewhat like thoſe of the Oak; *the Flowers (which are produced at the Wings of the Leaves) are labiated; the* Stamina *or Threads ſupply the Place of the* Creſt, *or Upper-Lip; the Beard or Lower-Lip of the Flower is divided into five Parts; the middle Segment (which is largeſt) is hollow like a Spoon, and ſometimes divided into two Parts; the Cup of the Flower is fiſtulous.*

The *Species* are;

1. CHAMÆDRYS *major repens. C. B.* The Greater Creeping Germander.
2. CHAMÆDRYS *minor repens. C. B.* The ſmaller Creeping Germander.
3. CHAMÆDRYS *laciniatis foliis. Lob.* Germander with cut Leaves.
4. CHAMÆDRYS *Hiſpanica tenuifolia multiflora. H. R. Par.* Narrow-leav'd *Spaniſh* Germander, with many Flowers.
5. CHAMÆDRYS *Alpina fruteſcens, folio ſplendente. Tourn.* Shrubby Germander of the *Alps*, with ſhining Leaves.
6. CHAMÆDRYS *fruticoſa Cretica, purpureo flore. Tourn.* Shrubby Germander of *Crete*, with a purple Flower.
7. CHAMÆDRYS *multifida ſpinoſa odorata. Vir. Luſit.* Prickly Sweet-ſmelling Germander, with Leaves divided into many Parts.

There are ſeveral other Varieties of this Plant, which are preſerv'd in the curious Gardens of Plants Abroad; but theſe mention'd are the principal Sorts to be found in the *Engliſh* Gardens. Theſe may be propagated, by ſowing their Seeds in the Spring in a Bed of freſh Earth in an open Situation; and when the Plants are come up, they may be tranſplanted either into ſmall Pots, or in Borders where they are intended to remain.

The ſixth and ſeventh Sorts ſhould have the Shelter of a Wall, Hedge, or Pale, to protect them from the North and Eaſt Winds, which are ſometimes deſtructive to them, if too much expos'd thereto. Theſe Sorts may alſo be increas'd, by planting their Cuttings in a ſhady Border, in *May* or *June*; which, if ſupply'd with Water in dry Weather, will take Root very well in about three Months Time, when they may be remov'd with Safety where they are deſign'd.

The third Sort is a biennial Plant, rarely abiding after it hath perfected its Seeds: This ſhould be ſown in a Border which is ſcreen'd from the cold Winds; and when the Plants are come up, they may be tranſplanted to a greater Diſtance in the ſame well-ſhelter'd Border: and the Spring following, the Plants will flower, and ſoon after will perfect their Seeds; which, if permitted to ſcatter upon the Ground, will ariſe of themſelves, without any more Trouble, and need only to be tranſplanted where the Plants are intended to remain.

The firſt and ſecond Sorts are very hardy, and propagate themſelves very faſt by their creeping Roots, which, if ſuffer'd to ſpread, as they are naturally inclin'd, will in a ſhort Time cover a large Spot of Ground: Therefore they ſhould be planted at a good Diſtance, and remov'd every Spring or Autumn, to prevent their over-running the Ground.

The ſecond Sort is preſcrib'd in the laſt *College Diſpenſatory*: But the firſt is our common Sort in *England*, which is what the Markets are ſupply'd withal: the ſecond being to be found only in curious Gardens of Plants.

CHAMÆLÆA; [Χαμαιλαῖα, of χαμαὶ, *low*, and 'Ελαία, an *Olive-Tree*, as tho' the *low Olive-Tree*, becauſe this Plant reſembles that Tree. It is alſo call'd *Chamælæa Tricoccos*, becauſe it bears three Seeds join'd together.] Widow-Wail.

The *Characters* are;

It hath a Flower conſiſting of one Leaf, which is deeply divided into three Parts; the Cup of the Flower is alſo of one Leaf, divided into three Segments; the Fruit conſiſts of three hard Berries cloſely joined together, in each of which is contain'd one oblong Seed; to which may be added, It hath the Appearance of a Shrub, and the Leaves are ſmall and oblong.

There is but one *Species* of this Plant in the *Engliſh* Gardens, which is;

CHAMÆLÆA *tricoccos. C. B.* The Widow-Wail.

This is a Shrub of low Growth, ſeldom ariſing above two or three Feet in Height with us, and is ſomewhat tender; therefore ſhould (if planted abroad) have a warm Poſition, and a dry Soil: It is uſually preſerv'd in Green-houſes in the Winter; but I find it will endure the Cold of our common Winters in the open Ground, if defended from the cold Winds.

This Plant is propagated by ſowing the Seeds, ſoon after they are ripe, in a Pot or Tub of Earth, which ſhould be ſhelter'd from Froſts in Winter, and the Earth ſuffer'd to remain undiſturb'd till the ſecond Year, when the Seeds will ariſe; which to promote, if you place the Pot into a gentle Hot-bed, it will greatly forward the Growth of the Plants. When the Plants are come up about ſix or eight Inches high, they may be tranſplanted ſingly into ſmall Pots, and ſcreen'd from the Sun until they have taken freſh Root: After which Time they ſhould be expos'd to the open Air; but for the two firſt Winters, while young, ſhould be ſhelter'd under a common Hot-bed Frame: But afterwards they may be turn'd out of the Pots into the full Ground, under a Wall, *&c.* (as was before directed) where they will abide very well. This Plant hath no great Beauty; nor do I know any Uſe made of it in *England*; and is only preſerv'd in curious Collections of Plants, for Variety-ſake.

CHAMÆMELUM, [Χαμαίμηλον, of χαμαὶ, and Μῆλον, an *Apple*; ſo call'd, becauſe it has the Scent of an Apple.] Camomile.

The *Characters* are;

It hath a fibroſe Root; the Cup of the Flower is ſquamoſe, which expands and appears like many Leaves; the Flowers are for the moſt part radiated; the Petals of the Flower are white, and the Diſk yellow; the Leaves are cut into five Segments.

The *Species* are;

1. CHAMÆMELUM *odoratiſſimum repens, flore ſimplici. J. B.* Sweet-ſcented creeping Camomile.
2. CHAMÆMELUM *repens odoratiſſimum perenne, flore multiplici. J. B.* Sweet-ſcented creeping Camomile, with double Flowers.
3. CHAMÆMELUM *vulgare amarum. J. B.* Common bitter Camomile.
4. CHAMÆMELUM *fœtidum. C. B.* Stinking Camomile or *May*-Weed.
5. CHAMÆMELUM *majus, folio tenuiſſimo, caule rubente. H. R. Par.* Larger Camomile, with narrow-cut Leaves, and reddiſh Stalks.
6. CHAMÆMELUM *leucanthemum Hiſpanicum, magno flore. C. B. Spaniſh* Camomile, with large Flowers.
7. CHAMÆMELUM *Chium vernum, folio craſſiori, flore magno. T. Cor.* Spring Thick-leav'd Camomile of Chio, with large Flowers.
8. CHAMÆMELUM *Orientale incanum, folio millefolii. T. Cor. Eaſtern* Camomile, with hoary narrow Leaves.
9. CHAMÆMELUM *Luſitanicum latifolium, ſive coronopi folio. Breyn.* Broad-leav'd *Portugal* Camomile.
10. CHAMÆMELUM *Æthiopicum lanuginoſum, flore albo. Breyn. Ethiopian* woolly Camomile, with a white Flower.
11. CHAMÆMELUM *Æthiopicum lanuginoſum, flore luteo. Boerh. Ind. Ethiopian* woolly Camomile, with a yellow Flower.
12. CHAMÆMELUM *Orientale, foliis pinnatis. T. Cor. Eaſtern* Camomile, with pennated Leaves.

There are ſeveral other Varieties of this Plant which are kept in curious *Botanick* Gardens; but theſe here mention'd are the principal Sorts we have at preſent in the *Engliſh* Gardens.

The firſt Sort is the common *Camomile* of the Shops, and is the only Kind which is propagated for Uſe in the *Engliſh* Gardens: This was formerly in great Requeſt for making of green Walks; but as it is very ſubject to rot in Winter, eſpecially when grown pretty thick, whereby the Walks planted therewith will have many bare Patches, and are thereby render'd very unſightly, it hath occaſion'd the Diſuſe of it for thoſe Purpoſes of late Years; but it is ſtill cultivated in *Phyſick* Gardens for medicinal Uſe, though it grows wild in great Plenty on moſt of the large Commons, or Heaths near *London*.

The ſecond Sort is preſerv'd in Gardens for the Variety of its very double Flowers; but is not ſo good for medicinal Uſes as the common, tho' at preſent it is more generally us'd.

There is alſo another Variety of this Plant, which is ſometimes found wild amongſt the common, that hath naked Flowers, being intirely deſtitute of *Petals*, or Flower-leaves.

Theſe three Sorts are eaſily propagated in a Garden, by parting their Roots, and planting them about eight or ten Inches diſtant every Way, for they are great Spreaders, eſpecially when planted in a good Soil. The beſt Seaſon for this Work is in *March*: They all thrive beſt in a poor Soil.

The third, fourth, and fifth Sorts are common Plants, in moſt Parts of *England*, and are rarely preſerv'd in Gardens, unleſs it be in publick *Botanick* Gardens, to increaſe the Number of Varieties.

The other Sorts, tho' Strangers in our Climate, yet will do very well if ſown in the Spring of the Year in an open Bed of freſh Earth, (except the tenth and eleventh Sorts, which are ſomewhat tender, and ſhould be firſt rais'd in a moderate Hot-bed, and may afterwards be tranſplanted abroad, where they will flower, and ripen their Seeds very well): They are moſt of them Annuals, therefore ſhould either be ſown every *Spring*, or their Seeds ſuffer'd to ſow themſelves, whereby the Labour may be ſav'd of preſerving their Seeds; and the Plants which ariſe from their Seeds in *Autumn*, if they ſtand the Winter, will flower early the ſucceeding Summer, and perfect their Seeds better than if ſown in the Spring.

Theſe Varieties are very proper for all curious Collections of Plants, but are ſeldom preſerv'd in Gardens for Uſe or Pleaſure.

CHAMÆMESPILUS; *vide* Meſpilus.

CHAMÆMORUS; [of χαμαὶ, and *Morum*, Lat. a *Mulberry*] Cloud-Berries, or Knot-Berries.

The *Characters* are;

It hath a pentapetalous Flower; the Fruit is compos'd of many Acini, *in Form of the* Mulberry.

There is but one *Species* of this Plant known in *England*, which is;

CHAMÆMORUS. *Cluſ. Hiſt.* Cloud-Berries, *vulgo*.

This Plant is found upon the Tops of the higheſt Hills in the North-part of *England*, but can't be cultivated in a Garden by any Art.

CHAMÆNERION; of Χαμαὶ, *Dwarf*, and Νήριον *a Roſe Bay*. *Geſner* calls this Plant *Filius ante Patrem*, i. e. *the Son before the Father*; becauſe, as it is well known, in other Plants the Flower is always prior to the Ovary: But this Fruit always appears before the Flower; but yet it is not before the Flower; for the Tube of the Ovary equally riſes among the *Stamina* of the Flower, and hence are equally fecundated, as in other Plants.

The *Characters* are;

The Calyx of the Flower conſiſts of four Leaves, which are long, ſlender, and are expanded; the Flowers are roſaceous, and conſiſt of four Leaves, which are ſucceeded by long ſquare Cods, which, when ripe, open into four Cells; in each of which are contain'd many downy Seeds.

The *Species* are;

1. CHAMÆNERION *villoſum, magno flore purpureo. Tourn.* Great hairy codded Loſeſtriſe, or Willow-Herb; *called alſo* Codlings and Cream.
2. CHAMÆNERION *latifolium vulgare. Tourn.* Broad-leav'd Willow-Herb, or Roſebay, *commonly called* French Willow.
3. CHAMÆNERION *latifolium vulgare, flore albo. Tourn.* Broad-leav'd Willow-Herb, or Roſebay, with white Flowers.

The firſt Sort is found very common by the Sides of Ditches in moſt Parts of *England*; but notwithſtanding its commonneſs, may be admitted into a large Garden, eſpecially if there happens to be a moiſt Place where few other Things will thrive, here this Plant will produce fair Flowers for two Months ſucceſſively.

The other two Sorts afford fine Spikes of beautiful Flowers, and deſerve a Place in ſome remote Corner of the Garden, for the Uſe of their Flowers to furniſh Baſons for Halls, Parlours, &c. but muſt not be planted amongſt other Flowers, for their Roots ſpread very far under the Surface of the Ground, and would thereby ſoon over-run and deſtroy whatever Flowers grew near them; nor ſhould they be permitted to ripen their Seeds, which will ſpread all over the Garden, and become very bad Weeds; the Stalks therefore ſhould be cut down before the Seeds are ſpread abroad by the Wind.

Theſe Sorts multiply faſt enough by Off-ſets, which may be planted either in *Spring* or *Autumn*, in any ſhady Part of the Garden, where they will thrive in almoſt any Soil, but beſt in that which is moiſt.

There are ſeveral other Varieties of this Plant, many of which are found wild in *England*, which are unworthy of a good Garden; therefore I ſhall omit mentioning them in this Place.

CHAMÆPITYS; [Χαμαιπίτυς, of χαμαὶ, and πίτυς, *a Pine-tree*, q. d. *Humble Pine*, becauſe the Leaves of this Plant reſemble the *Pine*.] Ground-Pine.

The *Characters* are;

The Leaves are narrow and trifid; the Flower is labiated: the Place of the Galea, or Creſt of the Flower, is ſupplied with little Teeth; the Beard (or lower Lip) is divided into three Parts, the middle Segment being again ſplit into two Parts; the Flowers rarely grow in Whorles, (as do moſt of this Tribe of Plants) but one or two Flowers are produc'd at the Wings of the Leaves.

The *Species* are ;

1. CHAMÆPITYS *lutea, vulgaris, ſive folio trifido.* *C. B.* Common yellow Ground-Pine.

2. CHAMÆPITYS *moſchata, foliis ſerratis, an prima Dioſcoridis.* *C. B.* Muſk Ground-Pine, with ſerrated Leaves.

There are ſeveral other Varieties of theſe Plants mention'd in Foreign Catalogues, but theſe two Sorts are all that I have ſeen growing in *England*.

The firſt Sort is found growing wild upon chalky Lands in many Parts of *England* : This may be cultivated in a Garden, if the Seeds are ſown ſoon after they are ripe ; for if it be kept till Spring, it ſeldom riſes well ; and if it doth come up, the Seeds are ſeldom perfected by Spring-Plants. This Sort is uſed in Medicine.

The ſecond Sort is preſerv'd in curious Gardens of Plants, but is ſeldom to be found in Pleaſure-Gardens, it being a Plant of no great Beauty : This is alſo an Annual, and may be cultivated in the ſame Manner with the former ; they both thrive beſt in a dry undung'd Soil.

CHAMÆRHODODENDRON, Sweet Mountain Roſe.

The *Characters* are ;

It hath a tubulous Flower conſiſting of one Leaf, ſhaped ſomewhat like a Funnel ; from whoſe Cup ariſes the Pointal, fixed like a Nail in the hinder Part of the Flower, which afterwards becomes an oblong Fruit, divided into five Cells, in which are contained many very ſmall Seeds.

The *Species* are ;

1. CHAMÆRHODODENDRON *Alpinum glabrum.* *Tourn.* Smooth Mountain Roſe of the *Alpes*.

2. CHAMÆRHODODENDRON *Alpinum villoſum.* *Tourn.* Hairy Mountain Roſe of the *Alpes*.

3. CHAMÆRHODODENDRON *Alpinum ſerpillifolium.* *Tourn.* Mountain Roſe of the *Alpes*, with a Mother of Thyme Leaf.

4. CHAMÆRHODODENDRON *Indicum, flore amplo coccineo.* *Tourn.* *Indian* Mountain Roſe, with a large ſcarlet Flower.

The firſt, ſecond, and third Sorts grow wild on the *Alpes*, as alſo upon ſeveral Hills in *Germany* and *Auſtria* ; but are with great Difficulty preſerved in Gardens in this Country. The beſt Method to cultivate theſe Plants is, to put them in Pots filled with freſh loamy Earth, and place them in a ſhady Situation, obſerving to water them conſtantly in dry Weather, otherwiſe they will ſoon decay ; for in their natural Situation they have frequent Rains, and very great Dews, whereby the Ground is kept continually moiſt ; ſo that, when theſe Plants are tranſplanted into a drier Situation, if they are not duly watered, they are ſoon deſtroyed.

They may be propagated by laying down their tender Branches early in the Spring, which, if duly watered, will take Root by the following Spring ; when they ſhould be ſeparated from the old Plants, and tranſplanted, either into Pots filled with freſh loamy Earth, or into ſome ſhady moiſt Border ; where, if they are duly watered in dry Weather, they will thrive, and produce their Flowers ; but they will not perfect their Seeds in this Country.

The fourth Sort is very tender ; therefore muſt be placed in a warm Stove in the Winter, otherwiſe it will not live in this Country. This Kind may be propagated by laying down the tender Branches, which will take Root in one Year, provided, they are duly watered : then they may be taken off from the old Plant, and each planted into a ſeparate ſmall Pot filled with freſh loamy Earth ; and if the Pots are placed in a moderate Hot-bed of Tanners-bark, and the Glaſſes ſhaded in the Heat of the Day, until the Plants have taken new Root, it will be a very ſafe Method to preſerve them, and will greatly promote their Growth.

The ſecond Year after theſe Layers are taken from the old Plants, they will produce Flowers, and continue ſo to do every Year after. Theſe Plants may be placed abroad in Summer ; but they muſt not be taken out of the Stove till the middle of *June*, and muſt be placed where they may be well defended from ſtrong Winds ; otherwiſe they will loſe their Leaves in Summer, which will prevent their flowering : nor ſhould they remain abroad too late in Autumn ; for if they remain ſo late as to be pinched by morning Froſts, they ſeldom ſurvive it ; for when the upper Leaves, and tender Shoots are nipped, the Shoots will decay ſoon after, and the whole Plant be ſoon deſtroyed. In Summer theſe Plants require to be plentifully watered ; but in Winter they ſhould not have too large Quantities, but muſt be frequently refreſhed.

CHAMÆRIPHES ; *vide* Palma.

CHAMÆRUBUS ; *vide* Rubus.

CHAMÆSYCE ; *vide* Tithymalus.

CHELIDONIUM Majus. The greater Celandine.

The *Characters* are ;

The Cup of the Flower conſiſts of two Leaves, which ſoon fall away ; the Flower hath four Leaves, which are expanded in Form of a Croſs ; the Ovary in the Baſe of the Flower, is ſurrounded by many Stamina *(or Threads) ; the Flowers ſoon fall away, and are ſucceeded by many bivalve Pods, which contain many ſmall round Seeds : And the whole Plant is full of a yellow hot Juice.*

The *Species* are ;

1. CHELIDONIUM *majus, vulgare.* *C. B.* Common Great Celandine.

2. CHELIDONIUM *majus, foliis quernis, flore laciniato.* *Mor. Hiſt.* Greater Celandine, with Leaves like the Oak, and laciniated Flowers.

3. CHELIDONIUM *majus, foliis & flore minutiſſime laciniatis.* *H. R. Par.* Greater Celandine, with fine cut Leaves and Flowers.

4. CHELIDONIUM *maximum Canadenſe acaulon.* *Corn.* Large *Canada* Celandine, without Stalks, *commonly called* Pocone.

The firſt Sort grows wild upon dry Banks and Walls in moſt Parts of *England*, and is brought to the Markets by the Herb-women, who gather it for Medicinal Uſe.

The ſecond Sort hath been found wild in ſome particular Places in *England*, particularly at *Wimbleton* in *Surry* : This Sort conſtantly retains its Difference when cultivated in a Garden, and ſown yearly ; the Seeds of this never producing any Plants of the common Sort amongſt them.

The third Sort is only to be found in curious Botanick Gardens, where it is preſerv'd for its Variety.

The fourth Sort was brought from *America* ; and altho' ſtiled *Canada* in its Title, yet is found in divers Parts of the Continent, as in *Virginia*, *Carolina*, *New-England*, &c. from whence I have received Plants of this Kind, which I find will endure our ſevereſt Winters in the open Ground, if planted near a Wall, Pale, *&c.* to defend it from the cold Winds. This flowers in *April*, and perfects its Seeds in *June* ; from which new Plants may be obtain'd, if ſown ſoon after it is ripe : But the eaſieſt Method to propagate this Plant, is by parting the Roots in *March*, which increaſe very faſt in a moiſt Soil.

The other Varieties may all be propagated by ſowing their Seeds ſoon after they are ripe, in any Corner of the Garden ; where, if ſuffer'd to caſt their Seeds, they will always furniſh a plentiful Stock of young Plants, without any farther Trouble.

CHELIDONIUM Minus ; [of χελιδὼν, *Gr. a Swallow* : The Poets having feign'd concerning this Plant, that it takes its Name from the Uſe which Swallows make of it ; for they tell us, that Swallows apply the Leaves of *Chelidony* to the Eyes of their young ones which are hatch'd blind, and by that means open them ; but 'tis certain from Natural Hiſtory, that all young Birds, when they are firſt excluded the Shell, have their Eyes cover'd with a Sort of a thin Membrane, as it is after ſome ſort in a human *Fœtus*, becauſe the Humours are not ſufficiently clear and pellucid, but turbid] Pilewort or leſſer Celandine.

The *Characters* are ;

It hath a grumoſe or granuloſe Root ; the Leaves are roundiſh ; the Flower-ſtalks trail upon the Ground ; the Cup of the Flower conſiſts of three Leaves ; the Flowers are roſaceous, conſiſting of five or more Leaves ; the Ovary becomes a globular Fruit, after the manner of the Ranunculus.

The *Species* are ;

1. CHELIDONIUM *minus.* *Dod.* The leſſer Celandine or Pilewort.

2. CHELIDONIUM *minus, flore pleno.* *Camer.* The leſſer Celandine, with double Flowers.

The firſt Sort grows wild by the Sides of Ditches, and in moiſt Meadows, in almoſt every Part of *England*, ſo that 'tis rarely kept in a Garden.

The ſecond Sort is a Variety of the firſt, which hath been found in the Meadows, and tranſplanted into ſeveral curious Gardens, where it continues to produce very double Flowers, and is, for Variety, worthy of a moiſt ſhady Border in the beſt Gardens: They both propagate themſelves by Roots very faſt, ſo that there needs no more Care with them than the firſt tranſplanting ſome Roots of the Sort you would preſerve, into ſome ſhady moiſt Spot of Ground, letting them remain undiſturb'd, and in a ſhort time they will furniſh a ſufficient Supply of Roots.

CHELONE, [Χελώνη, Gr. a *Tortoiſe.*]

The *Characters* are;

It hath a ſhort, green, ſquamoſe Calyx; the Flower conſiſts of one Leaf, which is divided into two Lips; the Galea *(or Creſt) is ſomewhat like the Head of a* Tortoiſe; *the Beard (or lower Lip) is extended beyond the Creſt, and is bifid; the Flower is ſucceeded by a Fruit which is in Shape like that of the* Fox-glove, *and is divided into two Cells, in which are contain'd many flat Seeds, that are furbelow'd on the Edges.*

There is but one *Species* of this Plant at preſent known in the *Engliſh* Gardens, which is,

Chelone, *Acadienſis, flore albo. Tourn.* White-flowering Chelone of *Acadia.*

Tho', by the Title of this Plant, it is ſuppos'd a Native of *Acadia* only, yet hath it been brought from divers Parts of *America*; and 'tis very probable may be found in moſt Parts of *North America*, as *Virginia*, *Maryland*, *New-England*, &c. From the two laſt mentioned Places ſeveral Plants have been ſent to *England* by ſome curious Perſons of thoſe Countries.

This Plant is very hardy, enduring our ſevereſt Cold in the open Ground: It is propagated by parting the Roots in the Spring, which increaſe very faſt under the Surface of the Earth; therefore it ſhould not be planted amongſt other curious Plants or Flowers, leſt, by its ſpreading Roots, it ſhould overbear and deſtroy them. It dies to the Surface every Winter, and ariſes again the ſucceeding Spring, producing its Flowers in *Auguſt*, and ripens its Seeds in *October*; which altho' it ſeems to be perfectly good almoſt every Year, yet I could never procure one ſingle Plant from all the Seeds I have yet ſown, either of my own ſaving, or ſuch as have been brought from Abroad.

CHENOPODIO-MORUS, [Χηνοπόδιον, of χὴν χηνὸς, a *Gooſe*, and ποῦς, a *Foot*, Gr. and *Morus*, a *Mulberry:* Becauſe the Leaves reſemble a Gooſe Foot; and the Fruit, that of a Mulberry] Mulberry Blight.

The *Characters* are;

The whole Plant hath the Appearance of a Blight; *but the Fruit is ſucculent, and in Shape like a* Mulberry *or* Strawberry.

The *Species* are;

1. Chenopodio-morus *major. Boer. Ind.* Great Mulberry Blight, *commonly called* Strawberry Spinage.
2. Chenopodio-morus *minor. Boerh. Ind.* Leſſer Mulberry Blight, *commonly called* Berry-bearing Orach.

Theſe two Plants are pretty Varieties in a Garden, being very proper to plant in Pots, to intermix with other annual Plants to adorn Court-yards, during the Summer and Autumn Seaſons; where (if the Plants are regularly train'd up to Sticks while young) their Fruit, with which every Part of the Plant will be fill'd doth make a very good Appearance.

Theſe Plants are propagated by ſowing their Seeds in the Spring in a gentle Hot-bed; and when the Plants are ſtrong enough to be tranſplanted, they may be planted in Pots of rich Earth, and expos'd to the open Air, giving them frequent Waterings, as the Seaſon may require; and as they advance in Height, they ſhould be kept ty'd up cloſe to Sticks, trimming off all the Side-branches: which, if permitted to remain on, would prevent the Plant from advancing in Height.

The Fruit of theſe Plants, if ſuffered to fall to the Ground, will come up again in the Autumn; which Plants, if potted, and ſhelter'd from ſevere Froſts, in a common Hot-bed Frame, will grow much larger than thoſe ſown in the Spring, and flower and produce their Fruit much earlier in the Seaſon: So that, by having Plants of both Seaſons, they may be continued in Beauty thro' the greateſt Part of the Summer and Autumn.

CHENOPODIUM, [Χηνοπόδιον, Gr.] Gooſe-foot or Wild Orach.

The *Characters* are;

The Seeds are ſingle and globoſe in ſome Species, *but in others they are compreſs'd; the Cup of the Flower is quinquifid (or divided into five Parts); the Leaves grow alternately upon the Stalks between the Seeds.*

The *Species* are;

1. Chenopodium *fœtidum. Tourn.* Stinking Orach.
2. Chenopodium *lini folio villoſo. Tourn.* Flax-leav'd Orach, *commonly called* Summer-Cypreſs or Belvedere.
3. Chenopodium *Ambroſioides, folio ſinuato. Tourn.* Cut-leav'd Orach, *commonly called* Oak of Jeruſalem.
4. Chenopodium *Ambroſioides Mexicanum. Tourn. Mexican* Orach, *commonly called* Oak of Cappadocia.
5. Chenopodium *Ambroſioides Mexicanum fruticoſum. Boerh. Ind.* Shrubby *Mexican* Orach.

The firſt of theſe Sorts is very common upon Dunghils, and in Gardens, in moſt Parts of *England:* It is ſeldom cultivated, except in ſome Phyſick Gardens: for the Markets in *London* are ſupplied with it by the Herb-women, who gather it wild.

The ſecond Sort is ſometimes cultivated in Gardens; 'tis a beautiful Plant, which naturally is diſpos'd to grow very cloſe and thick, and in as regular a Pyramid as if cut by Art. The Leaves are of a pleaſant Green: And were it not for that, it hath ſo much of the Appearance of a Cypreſs Tree, that at ſome Diſtance it might be taken for the ſame, by good Judges. The Seeds ſhould be ſown in Autumn: And in the Spring, when the Plants are come up, they may be planted into Pots of good Earth, and kept ſupplied with Water, in dry Weather: Theſe Pots may be intermix'd with other Plants, to adorn Court-yards, *&c.* where they will appear very handſome, until their Seeds begin to ſwell and grow heavy, which weigh down and diſplace the Branches: At which Time the Pots ſhould be remov'd to ſome abject Part of the Garden, to maturate their Seeds; which, if permitted to fall upon the Ground, will come up the next Spring: So that you need be at no more Trouble in propagating theſe Plants, but only to tranſplant them where you intend they ſhould grow.

The third Sort was formerly uſed in Medicine: But altho' it ſtill continues in the Catalogue of Simples annex'd to the *London Diſpenſatory*, yet is very ſeldom us'd at preſent. This Plant may be propagated by ſowing the Seeds in an open Border of good Earth in the Spring, where it will perfect its Seed in Autumn; which, if permitted to ſhed upon the Ground, will ariſe as the former.

The fourth and fifth Sorts were brought from *America*, where the Seeds are call'd *Worm-Seed*; I ſuppoſe, from ſome Quality contain'd in it, which deſtroys Worms in the Body.

The fourth Sort is propagated by ſowing the Seeds in the Spring (as the before-mention'd Sorts); and will perfect its Seed in Autumn; after which, the Plant decays to the Ground: But if the Root be preſerv'd in Shelter under a Hot-bed Frame, it will put forth again in the ſucceeding Spring.

The fifth Sort grows to be a ſmall Shrub, ariſing ſometimes to the Height of five or ſix Feet, and becomes woody. This may be propagated by planting Cuttings in a ſhady Border during any of the Summer Months; which ſhould be ſhaded until they have taken Root, and that will be in a Month's Time, or leſs: Then they ſhould be planted into Pots, that they may be ſhelter'd in the Winter under a Frame, where they will abide the Cold very well, being ſomewhat hardy, tho' they will not ſtand in the open Air. There is no great Beauty in theſe two Plants; but they are preſerv'd in Gardens, becauſe of the ſtrong Smell of their Leaves.

CHERRY-LAUREL. *Vide* Lauro-ceraſus.

CHERRY-TREE. *Vide* Ceraſus.

CHERVIL. *Vide* Chærefolium.

CHESNUT. *Vide* Caſtanea.

CHIVES, are the fine Threads of Flowers, or the little Knobs which grow on the Tops of theſe Threads.

CHIVES *Tipt with Pendants*, are the *Apices* of Flowers, having *Farina* hanging and ſhaking at their Points, as the *Tulip*, &c.

CHIVETS, are the ſmall Parts at the Roots of Plants, by which they are propagated.

CHONDRILLA; [of χονδρὸς, Gr. a *Cartilage.*] Gum-Succory.

The *Characters* are;

It hath a cylindrical Cup to the Flower, which is cut almoſt to the Bottom, (in ſeveral Species); the Seeds are oblong and narrow; in other reſpects it is like the Lettuce.

The *Species* are;

1. CHONDRILLA *cærulea altera, cichorei ſylveſtris folio. C. B.* Blue-flower'd Gum-Succory.
2. CHONDRILLA *cærulea laciniata latifolia. C. B.* Blue flower'd Gum-Succory, with broad cut Leaves.
3. CHONDRILLA *juncea viſcoſa arvenſis, quæ prima Dioſcoridis. C. B.* Clammy Gum-Succory, with Shoots like the *Ruſh.*
4. CHONDRILLA *hieracii folio, annua. Tourn.* The annual Gum-Succory, with Hawkweed Leaves.

There are ſeveral other Varieties of this Plant, which are preſerv'd in curious Botanick Gardens, for the ſake of Variety: But as there is very little Beauty in them, ſo they are hardly worth their ſtanding in a Pleaſure-Garden.

But whoever hath a Mind to propagate their ſeveral Species, may ſow their Seeds in an open Bed of common Earth in the Spring, where they will readily come up, and thrive exceedingly; and their Seeds being permitted to ſcatter upon the Ground, will come up and ſoon overſpread a Garden.

The three firſt Sorts are abiding Plants, and increaſe very much by their ſpreading Roots, which, if not confin'd, will in a ſhort time become very troubleſome Weeds in a Garden; as alſo, if their Seeds are ſuffer'd to ripen, they will be blown all over the Garden, and be full as bad as Sow-thiſtles.

CHRISTMAS-FLOWER, or Black Hellebore; *vide* Helleborus.

CHRISTOPHORIANA; [This Herb takes its Name of St. *Chriſtopher.*] Herb-*Chriſtopher.*

The *Characters* are;

The Flower conſiſts of five Leaves, which are plac'd orbicularly, and expand in Form of a Roſe; *in the Center of which ariſes the Ovary, which becomes a ſoft Fruit or Berry, of an oval Shape, and is fill'd with Seeds in a double Row, which for the moſt part adhere together.*

The *Species* are;

1. CHRISTOPHORIANA *vulgaris noſtras, racemoſa & ramoſa. Mor. Hiſt.* Common Herb-*Chriſtopher*, or Bane-berries.
2. CHRISTOPHORIANA *Americana racemoſa, baccis rubris. Mor. Hiſt. American* Herb-*Chriſtopher*, with red Berries.
3. CHRISTOPHORIANA *Americana racemoſa, baccis rubris, longo pediculo inſidentibus. Sarrac. American* Herb-*Chriſtopher*, with red Berries growing on long Foot-ſtalks.

The firſt of theſe Sorts is found in divers Places in *Yorkſhire*, *Cumberland*, *Northumberland*, and other Northern Counties of *England*; but is rarely met with in the Southern Parts, unleſs where it is preſerved in Gardens: This Plant may be propagated by ſowing the Seeds, or parting the Roots: It muſt have a ſhady moiſt Situation, where it will thrive very well.

The ſecond and third Sorts are only preſerv'd in curious Gardens of Plants, and are rarely met with in the *Engliſh* Gardens; they are very hardy, and will endure our Cold very well, if planted in the open Ground.

Theſe are propagated in the ſame manner as the former.

CHRYSANTHEMOIDES OSTEOSPERMON; [of χρυσάνθεμον; of χρυσὸς *Gold*, ἄνθεμος a *Flower*, and εἶδος *Form*, Gr. It is call'd *Oſteoſpermon*, of ὀστέον a *Bone*, and σπέρμα *Seed*, on account of the Hardneſs of its Seed.] Hard-ſeeded Chryſanthemum.

The *Characters* are;

The Leaves grow alternately upon the Branches; the Cup of the Flower is, for the moſt part, ſingle and ſcaly; the Flowers are radiated like a ſmall Sun-Flower; *the Ovary becomes a hard Seed.*

The *Species* are;

1. CHRYSANTHEMOIDES *Oſteoſpermon Africanum odoratum, ſpinoſum & viſcoſum. H. A. African* ſweet-ſcented, hard-ſeeded Chryſanthemum, with prickly Branches and viſcous Leaves.
2. CHRYSANTHEMOIDES *Oſteoſpermon, Africanum, arboreum, foliis populi albæ. Boerh. Ind. African* hard-ſeeded Tree-Chryſanthemum, with Leaves like the white Poplar.
3. *An.* CHRYSANTHEMOIDES, *quod Chryſanthemum ex inſulis Caribæis, leucoii incanis & ſericeis foliis, argenteis, craſſis. Pluk. Boerh. Ind.* Hard-ſeeded Chryſanthemum from the *Caribbee* Iſlands, with thick whitiſh Leaves.
4. *An.* CHRYSANTHEMOIDES, *quod Chryſanthemum Bermudenſe, leucoii foliis virentibus craſſis. Pluk.* Hard-ſeeded Chryſanthemum from *Bermudas*, with thick green Leaves.
5. *An.* CHRYSANTHEMOIDES, *quod Chryſanthemum Americanum, foliis virentibus, craſſis & dentatis. American* hard-ſeeded Chryſanthemum, with thick deep green Leaves indented on the Edges.

Theſe Plants are all of them propagated by planting their Cuttings in a Bed of rich Earth in any of the Summer Months, obſerving to ſcreen them from the Heat of the Sun until they have taken Root, which will be in about ſix Weeks or two Months after planting; at which time they ſhould be tranſplanted into Pots fill'd with light ſandy Earth, and ſet in a ſhady Place until their Roots are fix'd to the new Earth; then they may be expos'd to the open Air till *October*, at which time they ſhould be hous'd, with *Oranges*, *Myrtles*, &c. giving them as much free Air in mild Weather as is poſſible, by opening the Windows of the Green-houſe, and obſerving to refreſh them pretty often, for they all require in mild Weather much Water.

The three firſt mention'd Sorts are very hardy, and will endure to ſtand in a cold Green-houſe, with *Myrtles* and *Amomum Plinii's*, where if they are only protected from freezing, it will be ſufficient: But the two laſt mentioned having very ſucculent Branches, muſt have a warmer Poſition; for upon the leaſt Froſt touching their Branches, they are very apt to rot and decay.

Theſe Plants continue flowering the moſt Part of the Winter Seaſon, which renders them valuable, becauſe at that Time we have few other Plants which produce Flowers; and altho' theſe Flowers are not very beautiful, yet at that Seaſon every thing which appears like a Flower is acceptable, as putting us in Hopes of a ſucceeding Spring, when almoſt every thing without Doors is depriv'd of its former Verdure and Beauty.

CHRYSANTHEMUM; [χρυσάνθεμον, *Gr.* from χρυσὸς *Gold*, and ἄνθεμος a *Flower*; which is to ſay, *Golden Flower.*] Corn Marygold.

The *Characters* are;

It hath an annual Root; the Cup of the Flower is hemiſpherical, and ſcaly; the Flowers are radiated; the Rays being for the moſt part of a yellow Colour, and the Seeds are furrow'd.

The *Species* are;

1. CHRYSANTHEMUM *flore partim candido, partim luteo. C. B.* White Corn-Marygold, or Chryſanthemum.
2. CHRYSANTHEMUM *folio matricariæ, flore albo pleno. H. C.* The double white Chryſanthemum, or Corn-Marygold.
3. CHRYSANTHEMUM *Creticum luteum. H. Eyſt.* The yellow Chryſanthemum, or Corn-Marygold.
4. CHRYSANTHEMUM *folio matricariæ, flore luteo pleno. Boerh. Ind.* The double yellow Chryſanthemum, or Corn-Marygold.
5. CHRYSANTHEMUM *Creticum, petalis florum fiſtuloſis. Tourn.* The Quill-leav'd Chryſanthemum, or Corn-Marygold.

There are ſeveral other Varieties of this Plant; but as they are of leſs Note than theſe mention'd, and only preſerv'd in curious *Botanick* Gardens for their Variety, ſo I ſhall omit mentioning them in this Place.

Theſe Plants are all propagated by ſowing their Seeds in the Spring upon a gentle Hot-bed, in order to have them early; otherwiſe they will come up as well, if ſown in the open Ground: When the Plants are come up, they ſhould be tranſplanted into Nurſery-beds, at about ten Inches aſunder every way, where they may remain until they ſhew their Flowers, at which time you may tranſplant all thoſe which have double Flowers, either into Pots or Borders, to adorn the Pleaſure-Garden or Court-Yard. The ſingle ones may be pull'd up firſt, and caſt away as good for nothing, which will make room for the better, taking up the double ones, with a large Ball of Earth to their Roots, otherwiſe they will not bear removing when ſo far advanc'd. If theſe Plants are ſet in the full Ground, they will grow very large; therefore they ſhould be planted only in very large Borders, and not too near other Flowers, leſt by their over-bearing them they ſhould be deſtroy'd: But they are much handſomer when confin'd in Pots, provided they are conſtantly water'd; for by this means their Roots are kept within Compaſs, and the Plants ſeldom grow ſo large, but produce a greater Quantity of Flowers.

In ſaving the Seeds of theſe Plants, you ſhould always make choice of the very double Flowers, which will certainly produce a much greater Quantity of double Flowers the next Year, than would the Seeds of ſingle or half double Flowers; tho', if the Seeds are taken from the very beſt Flowers, they will degenerate, and bring ſome ſingle Flowers amongſt them: Therefore, to avoid this Diſappointment, the better Method is, when you have gotten ſome fine double Kinds of theſe Plants of both Colours, to take off ſome Cuttings of each Kind towards the latter End of *Auguſt*, or the Beginning of *September*, and plant them pretty cloſe, in Pots fill'd with common freſh Earth, ſetting them in a ſhady Place, and obſerving to water them frequently: Theſe Cuttings will, in a Month's time, ſtrike out Roots, and begin to grow; you muſt therefore remove the Pots into an open Situation, obſerving, as before, to refreſh them with Water, (which muſt now be done gently, that the young Plants may not grow too vigorous before Winter): In this Place they may remain until the latter End of *October*, when you ſhould place the Pots into a common Hot-bed Frame, that they may be ſcreen'd from ſevere Froſts, which would deſtroy them; but obſerve to take the Glaſſes off every Day, when the Weather will permit; otherwiſe the Plants will draw up and be very tender, ſo that upon the leaſt Impreſſion of Cold they will ſuffer very much; as alſo by being ſhut up cloſe, they would be ſubject to rot by the damp Air which ſurrounds them.

In the Spring theſe Plants may be tranſplanted out either into ſeparate Pots or Borders, as before directed, where they will flower early; and hereby you will be ſure to have the Sorts right, according to the Plants which the Cuttings were taken from.

CHRYSOSPLENIUM; [χρυσοσπλήνιον, of χρυσὸς *Gold*, and σπλὴν *the Spleen*, q. d. a *Plant* the Flowers of which are of a golden Colour, and good againſt Diſeaſes of the Spleen.] Golden Saxifrage.

The *Characters* are;

It hath a perennial fibroſe Root; the Calyx (or Flower-cup) is divided into four Parts; the Flower hath no viſible Petals, but hath eight Stamina, *or Threads, which ſurround the Ovary; the Pointal becomes a membraneous Veſſel, which is forked and bivalve, incloſing many ſmall Seeds.*

The *Species* are;

1. CHRYSOSPLENIUM *foliis amplioribus auriculatis. Tourn.* Golden Saxifrage, with large-ear'd Leaves.
2. CHRYSOSPLENIUM *foliis pediculis oblongis inſidentibus. Raii Syn.* Golden Saxifrage, with Leaves ſtanding on long Footſtalks.

Theſe two Plants are found growing wild in many Parts of *England*, upon marſhy Soils and Bogs, as alſo in moiſt ſhady Woods, and are ſeldom propagated in Gardens: where, if any Perſon have Curioſity to cultivate them, they muſt be planted in very moiſt ſhady Places, otherwiſe they will not thrive.

CIBOULS, or CHIBOULS; theſe are alſo cultivated by parting their Roots in Autumn, as was directed for *Eſcallions*, and to which they are nearly allied; but the great Diverſities of theſe Kinds, which were formerly cultivated in Kitchen Gardens, are now almoſt wholly neglected, it being found to little Purpoſe the propagating ſo many Kinds, when two or three will anſwer all the Purpoſes full as well.

CICER; [This Plant is call'd *Cicer*, of Κίκυς *Strength*; becauſe it is ſaid to ſtrengthen: It is alſo call'd *Arietana*, becauſe the Seeds of it reſemble the Head of a Ram.] Chiches, or Chick-Peaſe.

The *Characters* are;

It hath a Pea-ſhap'd (or papilionaceous) Flower, which is ſucceeded by ſhort ſwelling Pods; ſomewhat like the inflated Bladder of a Fiſh; the Seeds are ſhap'd ſomewhat like a Ram's Head.

The *Species* are;

1. CICER *ſativum, flore candido. C. B. P.* Garden Chiches, with a white Flower.
2. CICER *ſativum, ſemine rufo. C. B.* Manured Chiches, with reddiſh Seeds.
3. CICER *ſativum, ſemine nigro. C. B.* Manured Chiches, with black Seeds.
4. CICER *ſativum, flore ex rubro purpuraſcente, ſemine rubro. C. B.* Manured Chiches, with purpliſh red Flowers, and red Seeds.

There are ſome other Varieties of this Plant preſerved in curious Botanick Gardens abroad: but theſe here enumerated are the common Sorts, which are cultivated in the Kitchen-Gardens in *France*, *Italy*, *Spain*, &c. and, I believe, are all Seminal Varieties, which alter and change the Colour of their Flowers and Seeds, as do the common Garden-Beans.

This Plant is ſeldom cultivated in *England*, except in particular Gardens: nor do I think it worth planting for Uſe where Peas will do well, which are ſo much preferable for Goodneſs, and much greater Bearers, producing above double the Quantity upon the ſame Ground: but in warmer Countries, where our delicate Sorts of Peas ſeldom thrive well, theſe may ſupply their Place; and, perhaps, in thoſe Countries they are much more fruitful than with us.

The Seeds of theſe *Chiches* ſhould be ſown in *March*, in an open Situation, and upon a warm dry Soil, in Rows about two Feet aſunder, and as thick as Peas are uſually ſown in the Rows: When the Plants are come up, the Ground muſt be hough'd, and the Plants earth'd, as is practiſed for common Peas, to which this Plant agrees very well in its Culture. In *June* and *July* it will flower, and its Seeds will be ripe in *Auguſt* and *September*.

The People in *France* and *Italy* preſerve them for boiling in the Winter Seaſon, as we do our White and Grey Peas, to which theſe are ſomewhat akin.

CICHORIUM, [Χιχώριον, or κικόριον, of κιχέω, *I find*, becauſe it is found every-where in walking; or as others ſay, of κίω, *I go*, and χῶρος, *a Place*:] Succory.

The *Characters* are;

It is one of the Milky Plants, with a plain radiated Flower; the Flowers are produced from the Sides of the Branches, at the ſetting off of the Branches upon ſhort Foot-ſtalks; the Cup of the Flower is like a contracted Seed-veſſel; the Seeds are angular, umbilicated, and in Shape ſomewhat like a Wedge.

The *Species* are;

1. CICHORIUM *latifolium, ſive Endivia vulgaris. Tourn.* Common Broad-leav'd Endive.
2. CICHORIUM *anguſtifolium, ſive Endivia vulgaris. Tourn.* Common narrow-leav'd Endive.
3. CICHORIUM *criſpum. Tourn.* Curled Endive.
4. CICHORIUM *criſpum, anguſtifolium. Boerh. Ind.* Narrow-leav'd curled Endive.
5. CICHORIUM *ſylveſtre, ſive officinarum. C. B.* Wild Succory.

The firſt and ſecond Sorts of *Endive* are now wholly diſuſed in the Kitchen-Gardens, as being vaſtly inferior to the curled Kinds, which are by much the larger and handſomer Heads.

The Seaſons for ſowing their Seeds are in *May*, *June*, and *July*, at four or five different Times; for that which is firſt ſown is very ſubject to run to Seed, eſpecially if the Autumn prove warm and dry: but however, it is neceſſary to have a little ſown in the Decreaſe of the Moon in *May*, for the firſt Crop; and again in *June*, the Middle or latter End; and for the laſt Crop, about the Middle of *July*. Theſe Seeds ſhould be ſown in an open Situation, and a good rich Soil, but not too thick. When the Plants are come up, and grown to be about two Inches high, they muſt be tranſplanted into another good open Spot of Ground, at about ten Inches diſtant every Way, obſerving to trim off the Tops of the largeſt Leaves with your Knife before you plant them; as alſo to water them conſtantly every other Evening, until they have taken freſh Root: After which Time they will need no other Care, but to keep them clean from Weeds, until they have ſo ſpread as almoſt to meet and cover the Ground.

Then you ſhould provide a Parcel of ſmall Oſier Twigs (or Baſs-Mat) to tie up ſome of the largeſt to blanch; which ſhould be done in a dry Afternoon, when there is neither Dew nor Rain to moiſten the Leaves in the middle of the Plants, which would occaſion their rotting ſoon after their being ty'd up. The Manner of doing it is as follows; *viz.* You muſt firſt gather up all the inner Leaves of the Plant, in a regular Order, into one Hand, and then take up thoſe on the Outſide that are ſound, pulling off, and throwing away all the rotten and decay'd Leaves; obſerving to place the outſide Leaves all round the middle ones, as near as poſſible to the natural Order of their Growth, ſo as not to croſs each other: Then having got the whole Plant cloſe up in your Hand, tie it up with the Twig, *&c.* at about two Inches below the Top, very cloſe; and about a Week after go over the Plants again, and give them another Tie about the middle of the Plant, to prevent the Heart-Leaves from burſting out on one Side; which they are ſubject to do, as the Plants grow, if not prevented this Way.

In doing of this you need only tie up the largeſt Plants firſt, and ſo go over the Piece once a Week, as the Plants increaſe their Growth; by which means you will continue the Crop longer than if they were all ty'd up at one Time: For when they are quite blanch'd, which will be in three Weeks or a Month after tying, they will not hold ſound and good above ten Days or a Fortnight, eſpecially if the Seaſon proves wet: Therefore it is that I would adviſe to ſow at four different Seaſons, that you may have a Supply as long as the Weather will permit. But in order to this, you muſt tranſplant all the Plants of the laſt ſowing under warm Walls, Pales, or Hedges, to ſcreen the Plants from Froſt: And if the Winter ſhould prove very ſharp, you ſhould cover them with ſome Peas-haulm, or ſuch other light Covering, which ſhould be conſtantly taken off in mild Weather: Theſe Borders ſhould alſo be as dry as poſſible; for theſe Plants are very ſubject to rot, if planted in a moiſt Soil in Winter.

Altho' I before directed the tying up of the Plants to blanch them, yet this is only to be underſtood for the two firſt Sowings; for after *Michaelmas*, when the Nights begin to be froſty, thoſe Plants which are ſo far above-ground will be liable to be much prejudiced thereby; therefore the beſt Method is, to take up your Plants of the latter Sowings in a very dry Day, and with a large flat-pointed Dibble, plant them into the Sides of Trenches of Earth, which are laid very upright, ſide-ways, towards the Sun, with the Tops of the Plants only out of the Ground, ſo that the haſty Rains may run off, and the Plants be kept dry, and ſecured from Froſts.

The Plant thus planted, will be blanched fit for Uſe in about three Weeks Time; after which it will not keep good long: You ſhould therefore keep planting ſome freſh ones into Trenches every Fortnight at leaſt, that you may have a Supply: And thoſe which were laſt tranſplanted out of the Seed-beds, ſhould be preſerv'd till *February* or *March*, before they are planted to blanch; ſo that from this you may be ſupply'd until *April*, or later, according to the Seaſon: For at this laſt planting into the Trenches it will keep longer than in Winter; the Days growing longer, and the Sun advancing with more Strength, dries up the Moiſture much ſooner than in Winter, which prevents the rotting of theſe Plants.

When your *Endive* is blanch'd enough for Uſe, you muſt dig it up with a Spade; and after having clear'd it from all the outſide green and decay'd Leaves, you ſhould waſh it well in two or three different Waters, to clear it the better from Slugs and other Vermin, which commonly ſhelter themſelves amongſt the Leaves thereof; and then you may ſerve it up to the Table with other Sallading.

But in order to have a Supply of good Seeds for the next Seaſon, you muſt look over thoſe Borders where the laſt Crop was tranſplanted, before you put them into the Trenches to blanch; and make choice of ſome of the largeſt, ſoundeſt, and moſt curled Plants, in Number according to the Quantity of Seeds required: For a ſmall Family, a dozen good Plants will produce enough Seeds; and for a large, two Dozen, or thirty Plants.

Theſe ſhould be taken up and tranſplanted under a Hedge or Pale at about eighteen Inches diſtant, in one Row about ſix Inches from the Hedge, *&c.* This Work ſhould be done in the Beginning of *March*, if the Seaſon is mild, otherwiſe it may be deferr'd a Fortnight longer. When the Flower-ſtems begin to advance, they ſhould be ſupported with a Pack-thread, which ſhould be faſten'd to Nails drove into the Pale, or to the Stakes of the Hedge, and run along before the Stems, to draw them upright cloſe to the Hedge or Pale; otherwiſe they will be liable to break with the ſtrong Winds. Obſerve alſo to keep them clear from Weeds, and about the beginning of *July* your Seeds will begin to ripen: Therefore, as ſoon as you find the Seeds are quite ripe, you muſt cut off the Stalks, and expoſe them to the Sun upon a coarſe Cloth to dry; and then beat out the Seeds, which muſt be dried, and put up in Bags or Papers, and preſerv'd for Uſe in ſome dry Place. But I would here caution you, not to wait for all the Seeds upon the ſame Plant; for if ſo, all the firſt ripe and beſt of the Seeds will ſcatter and be loſt before the other are near ripe; ſo great a Difference is there in the Seeds of the ſame Plant being ripe.

The *wild Succory*, (of which there are ſome Varieties in the Colour of the Flowers) is ſeldom propagated in Gardens; it growing wild in unfrequented Lanes and Dunghils in divers Parts of *England*, where the Herb-women gather it, and ſupply the Markets for Medicinal Uſe.

CICUTA, properly ſignifies an Hollow intercepted between two Knots, of the Stalks or Reeds of which the Shepherds us'd to make their Pipes; as *Virgil* ſings:

> *Eſt mihi diſparibus ſeptem compacta Cicutis*
> *Fiſtula*———

CICUTA; Hemlock.

The *Characters* are;

The Leaves are cut into many minute Segments; the Petals of the Flower are bifid, Heart-ſhaped, and unequal; the Flower is ſucceeded by two ſhort channelled Seeds.

The *Species* are;

1. Cicuta *major. C. B.* Common or Greater Hemlock.
2. Cicuta *minor, petroſelino ſimilis. C. B.* Leſſer Hemlock, or Fool's Parſley.

There are ſome other Varieties of this Plant, preſerv'd in curious Botanick Gardens; but the two Sorts here mentioned, are what we find wild in *England*.

The firſt Sort grows to a conſiderable Height, and is chiefly found upon the Sides of dry Banks in many Parts of *England*: The Leaves of this Plant are of a ſhining green Colour, and the Stalks are full of purple Spots; by which it is eaſily diſtinguiſh'd from any Plants that reſemble it. This Sort is ſometimes uſed in Medicine; tho' by many People it is thought to have a noxious Quality: But the *Hemlock* of the Antients, which was ſuch deadly Poiſon, is generally ſuppos'd to be very different from this.

The ſecond Sort is of a ſmaller Growth, and ſo like *Parſley*, that ſome unſkilful Perſons have gather'd it, and us'd it as ſuch; by which ſeveral Perſons have ſuffer'd in their Health, and ſome have been deſtroy'd thereby.

Theſe Plants are never propagated in Gardens for Uſe, but are gather'd by the Herb-women in the Fields.

CICUTARIA; [is ſo call'd from its Likeneſs to *Cicuta*.] Baſtard Hemlock.

The *Characters* are;

The Root is large and thick; the Stalks are thick, hollow, and jointed; the Leaves are like the greater Hemlock, *but are thicker; the Seeds are long, thick, gibbous, and ſhaped ſomewhat like a Half-moon, and very much channelled.*

The *Species* are;

1. Cicutaria *latifolia fœtida. C. B.* Broad-leav'd ſtinking Baſtard Hemlock.
2. Cicutaria *fœtidiſſima, foliis atro-virentibus. Jeſſieu.* The moſt ſtinking Baſtard Hemlock, with dark green Leaves.

Theſe two Plants are ſeldom cultivated, unleſs in Botanick Gardens: They are of a very ſtrong rank Smell, and are thought to contain a poiſonous Quality. Whoever hath a mind to cultivate them, ſhould ſow their Seeds in a moiſt Soil in the Spring of the Year; and when the Plants are come up, they ſhould be planted out at about two Feet Diſtance, for they ſpread their Roots and Branches very far on either Side: The ſecond Year after ſowing they will produce ripe Seeds, but the Roots will abide many Years after.

CINARA, The Artichoke. See the Article *Artichoke*.

To this Article muſt be added,

Cinara *ſpinoſa, cujus pediculi eſitantur. C. B. P.* 383. Chardon or Cardoon, *vulgo*.

This Plant is propagated by Seeds, which ſhould be ſown on an open Bed of light rich Earth the Beginning of *March*; and when the Plants appear above-ground, they ſhould be carefully weeded, and in dry Weather often refreſhed with Water. By the Beginning of *May* the Plants will be fit to tranſplant; when you ſhould prepare ſome Beds of light rich Earth, into which they ſhould be tranſplanted, placing them in Rows one Foot aſunder, and eight Inches Diſtance Plant from Plant in the Rows; obſerving to water them conſtantly, until they have taken Root; after which Time they will require little more than to be kept clear from Weeds. About the Middle or latter End of *June*, the Plants will have acquired Strength enough to plant out for good; at which Time you muſt carefully dig a Spot of light rich Ground, into which you ſhould tranſplant the Plants, placing them in Rows at four Feet Diſtance every Way, obſerving to water them, until they have taken Root; after which you muſt keep them very clear from Weeds. In *Auguſt* theſe Plants will be fit to tie up, which muſt be performed in the following Manner: *viz.* You ſhould firſt prepare a Parcel of Hay-bands: Then, in a dry Day, you muſt gather up the Leaves regularly, as they were produced; and having taken them up as cloſe as poſſible without bruiſing them, you muſt faſten the Hay-band round them near the Top, ſo as to keep them up: Then with a Spade you muſt bank up the Earth round the Plants, leaving about ten Inches or a Foot of their Tops uncovered; being careful that the Earth does not get into the Center of the Plants, which would endanger their rooting. As the Plants advance in Height, ſo they muſt be earthed up from Time to Time, in the ſame Manner as is practiſed for *Celery*; by which Means moſt of the Earth between the Plants will be raiſed about them: for if they thrive kindly, they will grow to the Height of three Feet and a half, or four Feet; and will, when taken up for Uſe, be near three Feet in Length, when trimmed from their outer Leaves. And it is in this their Excellency conſiſts; for it is only the tender blanched Part which is valuable.

Thoſe Plants which were firſt tranſplanted out, will be fit for Uſe the Beginning of *September*; but thoſe which were later tranſplanted, will not be fit for Uſe until *October*; and ſome of them will continue until the End of *November*, or the Middle of *December*, provided the Seaſon be favourable; but in very wet Seaſons, or in ſevere Froſts, they often rot and decay.

In order to ſave Seeds of this Plant, you ſhould preſerve ſome of the ſtrongeſt and moſt vigorous Plants, obſerving in ſevere Froſts to cover them lightly with Straw, or Peas-haulm; which ſhould be conſtantly taken off in mild Weather, otherwiſe it will endanger the rotting of the Plants. In the Spring the Earth ſhould be taken from the Plants gradually, that the Stems may advance; and in *June* their Heads will be formed much like a ſmall Artichoke, but full of ſharp Thorns: In theſe Heads the Seeds are contained, and will be ripe in *Auguſt*.

CINERARIA. *Vide* Jacobæa.

CIRCEA; [Is ſaid to be ſo call'd from *Circe*, the famous *Enchantreſs*, ſaid to have inchanted *Ulyſſes* and his Companions: *Boerhaave* ſuppoſes it to be ſo call'd, becauſe the Fruit of this Plant takes hold of Peoples Cloaths, and by this Means draws them to it, as the Enchantreſs *Circe* was wont to do by her Inchantments] Enchanter's Night-ſhade.

The *Characters* are;

It hath a perennial creeping Root; the Leaves which are whole, and ſhaped ſomewhat like thoſe of Night-ſhade, *are placed alternately upon the Branches; the Flower conſiſts of two Leaves, which reſt upon a two-leaved Empalement; the Flowers are ſucceeded by a Pear-ſhaped Fruit, which is burry on the Outſide, and divided into two Cells; in each of which are contained, for the moſt Part, two oblong Seeds.*

The *Species* are;

1. Circea *Lutetiana. Lob. Icon.* Enchanter's Night-ſhade.

2. Circea *minima. Col.* The ſmalleſt Enchanter's Night-ſhade.

The firſt of theſe Plants is very common in moiſt ſhady Places, and under Hedges, in moſt Parts of *England*; but the ſecond hath not been found wild with us, tho' it grows in Plenty in the Woods near the *Hague*, where I gather'd it, and brought it into *England*, where it continues to retain its Difference from the common Sort, notwithſtanding ſome People have ſuppoſed it to be the ſame. They are both great Runners in a Garden; for which Reaſon they ſhould be planted (by thoſe who would keep them for Variety) in ſome abject ſhady Part of the Garden, where few other Things will grow.

CIRCULATION of the Sap. *Vide* Sap.

CIRRI; are thoſe fine Strings, or Hairs, by which ſome Plants faſten themſelves, in order to their Support, as *Ivy*, &c.

CIRSIUM; [is ſo called of Κίρσος, a *Circle*, the fartheſt or laſt Inteſtine, *i. e.* the *Hæmorrhoides*, or Inflammation of the the *Anus*; becauſe it is wont to be uſed to cure that Diſtemper.] Soft or Gentle Thiſtle.

The *Characters* are;

It hath Leaves and Flowers very like thoſe of the Thiſtle; *but the Spines upon the Leaves are ſofter, and the Cup of the Flower is deſtitute of Spines.*

The *Species* are;

1. Cirsium *Anglicum. Ger.* The *Engliſh* Soft or Gentle Thiſtle.

2. Cirsium *Britannicum, Cluſii repens. J. B.* The great *Engliſh* Soft Gentle or Melancholy Thiſtle.

3. Cirsium *maximum, Aſphodeli radice. C. B.* The greateſt *Aſphodel-rooted* Gentle Thiſtle.

4. Cirsium *maculis argenteis notatum. Tourn.* The White-ſpotted Gentle Thiſtle.

There are ſeveral other *Species* of this Plant which are preſerved in curious Gardens of Plants; but as there is little Uſe or Beauty in them, ſo I ſhall paſs them over in this Place.

The two firſt Species here named, grow wild in *England*; the other two are Strangers, and only preſerved for Variety in ſome few Gardens: They may all be propagated by ſowing their Seeds in the Spring, in almoſt any Soil, but they require an open Situation; and when the Plants come up, they ſhould be ſeparated to about two Feet Diſtance, for they ſpread very far, eſpecially the two firſt, which are terrible Creepers underground, and therefore ſhould not be placed near other Plants, leſt they over-bear and deſtroy them. The three firſt Sorts are alſo increaſed by parting their Roots; but the laſt is an Annual, and muſt either be ſown every Spring, or the Seeds ſuffered to ſhed upon the Ground, which will come up without any Trouble.

CISTUS; [is ſo call'd from Κίϛος, or Κίσθος, Gr. *Ivy*, becauſe the Antients believed the Leaves of this Plant did reſemble the *Ground-Ivy*; or becauſe its little ſeminal Veſſel is incloſed in a *Ciſta* or little Cheſt, as it were.] Rock Roſe.

The *Characters* are;

It hath the Appearance of a Tree; the Leaves are produced by Pairs oppoſite upon the Branches; the Cup of the Flower conſiſts of three or five Leaves; the Flower conſiſts of many Leaves, which are expanded in Form of a Roſe, *having Abundance of* Stamina *or Threads in the Middle; from the Center of the Cup ariſes the Ovary, which is rough and hemiſpherical, and becomes a roundiſh or pointed Veſſel, conſiſting of many Cells, in which are contained many ſmall Seeds.*

The *Species* are;

1. Cistus *mas, folio oblongo incano. C. B.* The Male Ciſtus or Rock Roſe, with oblong hoary Leaves.

2. Cistus *mas major, folio rotundiori. J. B.* The greateſt Male Ciſtus, or Rock Roſe, with roundiſh Leaves.

3. Cistus *mas, folio breviori. J. B.* Short-leav'd Male Ciſtus, or Rock Roſe.

4. Cistus *mas, foliis undulatis & criſpis. Tourn.* Male Ciſtus, or Rock Roſe, with waved and curled Leaves.

5. Cistus *ladanifera Monſpelienſium. C. B.* The Gum-bearing Ciſtus, or Rock Roſe of *Montpelier*.

6. Cistus *ladanifera Hiſpanica, ſalicis folio, flore candido. Tourn. Spaniſh* Gum-bearing Ciſtus, or Rock Roſe, with Willow Leaves and white Flowers.

7. Cistus *ladanifera Hiſpanica, ſalicis folio, flore albo, macula punicante inſignito. Tourn. Spaniſh* Gum-bearing Ciſtus, or Rock Roſe, with Willow Leaves, and white Flowers ſpotted with Purple.

8. Cistus *Ledon, latifolium Creticum. J. B.* Sweet broad-leav'd Ciſtus, or Rock Roſe from *Crete*.

9. Cistus *Ledon, foliis populi nigræ, major. C. B.* Large ſweet Ciſtus, or Rock Roſe, with black Poplar Leaves.

10. Cistus *Ledon, foliis populi nigræ, minor. C. B.* Small ſweet Ciſtus, or Rock Roſe, with black Poplar Leaves.

11. Cistus *ladanifera Cretica, flore purpureo. Tourn. Cor.*

Sweet Gum-bearing Ciſtus, or Rock Roſe from *Crete*, with purple Flowers.

The various Kinds of theſe Plants are very great Ornaments to a Garden; their Flowers are produc'd in great Plenty all over the Shrubs, which tho' but of a ſhort Duration, yet are ſucceeded by freſh ones almoſt every Day for above two Months ſucceſſively. Theſe Flowers are many of them about the Bigneſs of a middling Roſe, but ſingle, and of different Colours; the Plant continues green throughout the Year.

The firſt five and the eighth Sort will endure the Cold of our common Winters in the open Ground, provided they are planted in a dry Soil, and in a Situation where they may be ſhelter'd from the cold Winds, and will riſe to the Height of five or ſix Feet, and may be eaſily train'd to form handſome Heads. Theſe being intermix'd with flowering Shrubs of the ſame Growth, in ſmall Wilderneſs Quarters, *&c.* add greatly to the Variety, and their Flowers continuing to ſhew themſelves thro' the greateſt Part of the Summer, renders them worthy of a Place in the beſt Gardens. The other Sorts are commonly preſerv'd in Pots, and hous'd in Winter, tho' I believe moſt of them might be brought to ſtand abroad in Places that are well defended from the Cold.

Theſe Sorts may all be propagated, by ſowing their Seeds upon a gentle Hot-bed, or on a warm Border in the common Ground in *March*; and when the Plants are come up about three Inches high, they ſhould be tranſplanted either into ſmall Pots, or a Border of good light Earth, at about ten Inches Diſtance every Way: If they are planted into Pots, they ſhould be remov'd under a common Hot-bed Frame in Winter, to defend them from the Froſt, which may be hurtful to them while young, if they are not protected from it; but they ſhould have as much open free Air as poſſible in mild Weather, and will require to be often refreſh'd with Water.

In the Spring following, theſe Plants may be turned out of the Pots, with all the Earth preſerv'd to their Roots, and planted in the Places where they are to remain, (for they are bad Plants to remove when grown old) obſerving to give them now and then a little Water, until they have taken freſh Roots; after which Time they will require no farther Care than to train them upright in the Manner you would have them grow: But thoſe Plants which were at firſt planted into a Border in the open Ground, ſhould be arched over, and covered with Mats in froſty Weather, during the firſt Winter, but may be tranſplanted abroad the ſucceeding Spring: In removing of theſe Plants, you ſhould be careful to preſerve as much Earth about their Roots as you can; and if the Seaſon ſhould prove hot and dry, you muſt water and ſhade them, until they have taken freſh Root; after which they will require no other Culture than was before directed.

Theſe Plants may alſo be propagated, by planting Cuttings of them upon a gentle warm Bed in *May* or *June*, keeping them ſhaded with Mats, and frequently refreſhed with Water, until they have taken Root, which will be in about two Months Time; when you may tranſplant them into Pots filled with good freſh light Earth, which ſhould be ſet in a ſhady Place until they have taken Root, and then may be expoſed to the open Sun until *October*, when you ſhould remove them into Shelter the firſt Winter; but the ſucceeding Spring you may plant them abroad, as was before directed for the Seedling Plants.

The ſeventh Sort is by much the moſt beautiful of all theſe *Ciſtus's*: The Flowers, which are as big as a handſome Roſe, are of a fine White, with a deep purple Spot on the Bottom of each Leaf. This Plant alſo abounds with a ſweet glutinous Liquor, which exſudes thro' the Pores of the Leaves in ſo plentiful a manner, in hot Weather, that the Surfaces of the Leaves are coveerd therewith. From this Plant (*Cluſius* thinks) might be gathered great Quantities of the *Laudanum*, which is uſed in Medicine, in the Woods in *Spain*, where he ſaw vaſt Quantities of this Shrub growing.

But it is from the eleventh Sort, which Monſieur *Tournefort* ſays, the *Greeks*, in the *Archipelago*, gather this ſweet Gum: In the doing of which (*Bellonius* ſays) they make uſe of an Inſtrument like a Rake, without Teeth, which they call *Ergaſtiri*: To this are tied many Thongs of raw and untanned Leather, which they rub gently upon the Buſhes, that produce the *Ladanum*, that ſo that liquid Moiſture may ſtick upon the Thongs. After which they ſcrape it off with Knives: This is done in the hotteſt Time of the Day; for which Reaſon, the Labour of gathering this *Ladanum* is exceſſive, and almoſt intolerable, ſince they are obliged to remain on the Mountains for whole Days together, in the very Heat of Summer, or the *Dog-Days*: Nor is there any Perſon almoſt that will undertake this Labour, except the *Greek* Monks.

Monſieur *Tournefort* alſo relates the ſame in his *Travels*, where he ſays, That the Shrubs which produce the *Ladanum* grow upon dry ſandy Hillocks, and that he obſerved ſeveral Country Fellows in their Shirts and Drawers, that were bruſhing the Shrubs with their Whips, the Straps whereof, by being drawn over the Leaves of the Plant, licked up a ſort of odoriferous Balſam ſticking upon the Leaves, which he ſuppoſes to be Part of the nutritious Juice of the Plant which exſudes thro' the Pores of the Leaves, where it remains like a fattiſh Dew, in ſhining Drops as clear as Turpentine.

When the Whips are ſufficiently laden with this Greaſe, they take a Knife, and ſcrape it clean off the Straps, and make it up into a Maſs of Cakes of different Sizes: This is what comes to us under the Name of *Ladanum* or *Labdanum*. A Man that is diligent, will gather three Pounds two Ounces *per* Day, or more, which they ſell for a Crown on the Spot. This Work is rather unpleaſant than laborious; becauſe it muſt be done in the hotteſt Time of the Day, and in the greateſt Calm. And yet the pureſt *Ladanum* is not free from Filth; becauſe the Winds of the preceding Days have blown Duſt upon theſe Shrubs, which, by the glewy Subſtance upon the Surfaces of the Leaves, is thereby detained and mixed therewith. But to add Weight to this Drug, they knead it up with a very fine blackiſh Sand, which is found in thoſe Parts; as if Nature herſelf was minded to teach them how to adulterate this Commodity. It is no eaſy Thing to diſcover this Cheat, when the Sand has been well blended with the *Ladanum*: In order to which you muſt chew it for ſome Time, to find whether it crackles between the Teeth; and if it doth, you muſt firſt diſſolve it, and then ſtrain it, in order to purify away what has been added to it.

CITREUM; [Κιτρία, *Gr.*] The Citron-Tree.

The *Characters* are;

It hath broad ſtiff Leaves like thoſe of the Laurel, but without any Appendix (as hath the Orange); the Flowers conſiſt of many Leaves, which expand in Form of a Roſe; the Cup of the Flower is ſlender and fleſhy, and is divided into five Segments at the Top; the Piſtil of the Flower becomes an oblong, thick, fleſhy Fruit, which is divided into many Cells, is very full of Juice, and contains ſeveral hard Seeds.

The *Species* are;

1. Citreum *vulgare. Tourn.* The Common or ordinary Citron.
2. Citreum *dulci medulla. Tourn.* The Sweet Citron.
3. Citreum *magno fructu. Tourn.* The Large Citron.
4. Citrioides, *vulgo* Citratum *Florentinum, fructu magno, plerumque turbinato, lævi ac ſuavi medulla, cortice odoratiſſimo, foliis longioribus Citro. Hort. Piſſ. Florentine* Citron, with large ſweet Fruit, of a ſweet-ſmelling Kind, and long Leaves.
5. Citrioides, *ſeu* Citratum *Florentinum, fructu mucronato & recurvo, cortice verrucoſo odoratiſſimo. Hort. Piſſ. Florentine* Citron, with a pointed Fruit, which is recurved, and a warted ſweet-ſmelling Kind.
6. Citrioides *ſeu* Citratum *Florentinum, fructu minori, fere rotundo, acriori medulla, cortice odoratiſſimo. Hort. Piſſ. Florentine* Citron with ſmall roundiſh Fruit, with a ſharp Taſte, and ſweet-ſmelling Kind.
7. Citrioides, *ſeu* Citratum *Florentinum odoratiſſimum, fructu prolifero. Hort. Piſſ.* Sweet-ſmelling *Florentine* Citron, with Fruit coming out of each other.

There are ſeveral other Varieties of this Fruit, with which the *Engliſh* Gardens have been ſupply'd from *Genoa*, where is the great Nurſery for the ſeveral Parts of *Europe* for this Sort of Trees: And the Gardeners who cultivate them there, are as fond of introducing a new Variety to their Collection, as the Nurſery-men in *England* are of a new *Pear*, *Apple*, *Peach*, &c. So that the Varieties being annually increaſed, as are many of our Fruits from Seeds, there is like to be no End of the Variety of theſe, nor of the *Orange* and *Lemon-Trees*.

The moſt valuable Kind of theſe Fruits is the fifth, which is in ſo great Eſteem, that the ſingle Fruits are ſold at *Florence* for Two Shillings each, and are ſent as Preſents to the Courts of Princes. This Fruit is not to be had in Perfection in any other Parts of *Italy* but in the Plain between *Piſa* and *Leghorn*: And altho' Trees of this Kind have been tranſplanted from that Spot to divers other Parts of *Italy*, yet they are found to loſe much of that excellent Taſte with which they abound in thoſe Plains.

The ſeveral Sorts of *Citrons* are cultivated much in the ſame manner as the *Orange-Tree*; to which I ſhall refer the Reader, to avoid Repetition: but ſhall only remark, that theſe are ſomewhat tenderer than the *Orange*, and ſhould therefore have a warmer Situation in Winter; otherwiſe, they are very ſubject to caſt their Fruit. They ſhould alſo continue a little longer in the Houſe in the Spring, and be carry'd in again ſooner in the Autumn; as alſo to have a warmer and better-defended Situation in the Summer, though not too much expos'd to the Sun in the Heat of the Day.

And as their Leaves are larger, and their Shoots ſtronger than thoſe of the *Orange*, ſo do they require a greater Plenty of Water in the Summer; and in Winter they ſhould have but little Water at each Time, which muſt be the oftener repeated. The Soil ought to be much the ſame as for the *Orange-Tree*, but not quite ſo ſtrong.

The Common Citron is by much the beſt Stock to bud any of the *Orange* or *Lemon* Kinds upon; it being the ſtraiteſt and freeſt growing Tree. The Rind is ſmoother, and the Wood leſs knotty, than either the *Orange* or *Lemon*, and will take either Sort full as well as its own Kind; which is what none of the other Sorts will do. And theſe Stocks, if rightly managed, will be very ſtrong the ſecond Year after ſowing, and capable to receive any Buds, and will have Strength to force them out vigorouſly; whereas it often happens, when theſe Buds are inoculated into weak Stocks, they frequently die, or remain till the ſecond Year before they put out: And thoſe that do ſhoot the next Spring after budding, are oftentimes ſo weak as hardly to be fit to remain, as being incapable to make a ſtrait handſome Stem, which is the great Beauty of theſe Trees.

CITRUL, *vide* Pepo.

CLARY, *vide* Horminum or Sclarea.

CLAVICLE, [*Claviculus*, Lat.] a Claſper or Tendril.

CLEMATITIS; [Κληματῖτις of Κλῆμα, a *Twig*, or *Claſper*, &c. becauſe it climbs up Trees with Claſpers, like thoſe of Vines. Hence it is alſo call'd *Virgultum ductile*, *Ranunculus obſequoſus*; and alſo *Antrogenomene*, and *Flammula*, as tho' producing a Carbuncle: For the Leaves being bruis'd and apply'd to the Skin, burn it into Carbuncles, as it is in the Peſtilence: and *Flammula*; becauſe if one Leaf be cropp'd in a hot Day in the Summer-ſeaſon, and bruis'd, and preſently put to the Noſtrils, it will cauſe a Smell and Pain like a Flame].

The *Characters* are;

It hath a perennial fibroſe Root; the Leaves grow oppoſite upon the Stalks; the Flowers, which conſiſt for the moſt part of four Leaves plac'd in Form of a Croſs, are naked, having no Calyx; *in the Center of the Flower are many hairy* Stamina *(or Threads) which ſurround the Pointal; the Pointal afterwards becomes a Fruit, in which the Seeds are gathered, as it were, into a little Head, ending in a kind of Plume.*

The *Species* are;

1. Clematitis, *ſive Flammula ſurrecta alba. C. B.* Upright White Climber.
2. Clematitis *cærulea erecta. C. B.* Upright Blue Climber.
3. Clematitis *Hiſpanica ſurrecta altera, & humilior, flore albicante. H. R. Par.* Low *Spaniſh* Climber, with a whitiſh Flower.
4. Clematitis *ſylveſtris latifolia. C. B.* Great Wild Climber or Travellers Joy.
5. Clematitis *ſylveſtris latifolia, foliis non inciſis. Tourn.* Great Wild Climber or Travellers Joy, with undivided Leaves.
6. Clematitis *peregrina, foliis pyri inciſis. C. B. Spaniſh* Climber or Travellers Joy, with cut Leaves.
7. Clematitis *Canadenſis trifolia dentata, flore albo. H. R. Par.* Three-leav'd *Canada* Climber, with a white Flower.
8. Clematitis *cærulea, vel purpurea repens. C. B.* Purple creeping Climber or ſingle Virgins Bower, *vulgo.*
9. Clematitis *cærulea, flore pleno. C. B.* Blue Climber with a double Flower, or double Virgins Bower, *vulgo.*
10. Clematitis *repens rubra. Boerh. Ind.* Red creeping Climber.
11. Clematitis *Orientalis, folio Apii, flore ex viridi flaveſcente, poſterius reflexo. T. C.* Eaſtern Climber, with a Smallage Leaf, and a reflex'd Flower of a greeniſh Yellow.
12. Clematitis *purpurea repens, petalis florum coriaceis. Baniſt. Cat.* Purple creeping Climber, with ſtiff Petals.

The firſt, ſecond and third Sorts die to the Surface of the Ground every Winter; but their Roots are of long Continuance, ariſing again in the Spring. The ſecond and third uſually grow with us about three or four Feet high, and produce great Quantities of Flowers; but the firſt Sort is of humbler Growth, ſeldom riſing above eighteen Inches high, but in other reſpects it is very like the third.

Theſe Plants are propagated either by Seeds, or parting of their Roots: But the former being a tedious Method, (the Plants ſeldom riſing until the ſecond Year after ſowing, and are often two Years more before they flower) the latter is generally practis'd. The beſt Seaſon for parting theſe Roots, is either in *October* or *February*; either juſt before their Branches decay, or before they riſe again in the Spring.

They will grow almoſt in any Soil or Situation: But if the Soil is very dry, they ſhould always be new planted in the Autumn, otherwiſe their Flowers will not be ſo ſtrong: But if the Soil be wet, it is better to defer it until the Spring. The Roots may be cut through their Crowns with a ſharp Knife, obſerving to preſerve to every Off-ſet ſome good Buds or Eyes; and then it matters not how ſmall you divide them, for their Roots increaſe very faſt. But if you part them very ſmall, you ſhould let them remain two Years before they are again remov'd; that the ſecond Year their Flowers may be ſtrong, and the Roots multiply'd in Eyes, which in one Year's Time cannot be obtain'd.

Theſe Plants are extreme hardy, enduring the Cold of our ſevereſt Winters in the open Air; and are very proper Ornaments for large Gardens, either to be planted in large Borders, or intermix'd with other hardy Flower-Roots in Quarters of flowering Shrubs; where, by being plac'd promiſcuouſly in little open Places, they fill up thoſe little Vacancies, and are agreeable enough. They begin to flower about the beginning of *June*, and often continue to produce freſh Flowers until *October*; which renders them valuable, eſpecially ſince they require very little Care in their Culture; for their Roots may be ſuffer'd to remain ſeveral Years undiſturb'd, if we do not want to part them, which will not in the leaſt prejudice them.

The fourth and fifth Sorts are found wild in moſt Parts of *England*, eſpecially the fourth, which grows upon the Sides of Banks, under Hedges, and extends its trailing Branches over the Trees and Shrubs that are near it: This Plant in the Autumn is generally cover'd with Seeds which are collected into little Heads, each of which having, as it were, a rough Plume faſten'd to it, hath occaſion'd the Country People to give it the Name of *Old Man's Beard*. The fifth Sort being no more than an accidental Variety of the fourth, is often found intermix'd therewith.

The ſixth Sort is an *Ever-green*, and altho' it be a Native of a warm Country, yet I find it hardy enough to endure the Cold of our Climate in the open Air: This Plant commonly produces vaſt Quantities of large greeniſh yellow Flowers in the Depth of Winter, (provided it is not retarded by very ſevere Weather); for which Reaſon, together with the Beauty of its verdant green Leaves at that Seaſon, it deſerves a Place in every good Garden.

The ſeventh Sort is very like the fourth, which is our common Sort, from which it only differs in having but three Lobes to each Leaf, whereas ours have five or more.

The eighth and tenth Sorts, which are the moſt common in *Spain* and *Italy*, are at preſent very rare in *England*, being only to be found in curious Botanick Gardens: But the ninth Sort, which is a Variety of the eighth, is propagated in many Nurſeries near *London*, (but particularly in that of Mr. *Chriſtopher Gray*, near *Fulham*; where, amongſt many other curious Exotick Trees and Shrubs, I ſaw this in very great Plenty): This Sort produces very double Flowers in great Quantities all over the Plant, which continue at leaſt two Months, and render it valuable.

The eleventh and twelfth Sorts are alſo uncommon in *England* at preſent: The eleventh was brought from the *Levant* by Monſ. *Tournefort*, the chief Botaniſt to the late King of *France*. The twelfth was brought from *America*, where it is found in divers Parts in great Plenty, but particularly in *Virginia* and *North Carolina*; from whence I have receiv'd Seeds of this Plant, which have grown with me in the *Phyſick* Garden.

The nine laſt-mention'd Sorts are all of them trailing Plants, ſome of them growing to a very great Length, particularly the fourth, fifth and ſeventh Sorts, which ſhould be planted in large Wilderneſs Quarters, near the Stems of great Trees, to which they ſhould be train'd up, where, by their wild Appearance, they will be agreeable enough.

The other Sorts are proper enough to intermix with flowering Shrubs of a middling Growth, where, being faſten'd to ſtrong Stakes, they will riſe about ſix or ſeven Feet high, and produce great Quantities of Flowers. Theſe may alſo be planted to cover Seats in Wilderneſs Quarters, that are deſign'd for Shade; to which Purpoſe theſe Plants are very well adapted, requiring little more Care than to train their Branches regularly at firſt, after which they will maintain themſelves very well.

Theſe Plants are propagated by laying down their tender Branches (as is practis'd for Vines) in the Spring, which in one Year's Time will take Root, and may then be remov'd to the Places where they are deſign'd to remain; which ſhould be done in the Spring, obſerving to lay a little Mulch upon the Surface of the Ground round their Roots, and to water them gently in dry Weather: In two Years after planting they will make very ſtrong Shoots, which ſhould be train'd up to Stakes, that they may not trail upon the Ground, which would ſpoil their flowering, and render them very unſightly. From this Time they will require no farther Care, than to cut out every other Year the decay'd Branches; and in the Spring, to ſhorten ſuch Branches as may have grown too long and rambling for the Places where they are planted.

Theſe alſo may be rais'd from Seeds, which ſhould be ſown either ſo ſoon as ripe, or very early in the Spring, in a Bed of freſh light Earth, or in Pots or Boxes fill'd with ſome Earth, becauſe the Seeds of moſt of theſe Plants remain in the Ground until the ſecond Spring before they appear, eſpecially if they were not ſown in Autumn. When the Plants come up, they muſt be carefully clean'd from Weeds: and in very dry Weather frequently water'd; and in the ſucceeding Spring they ſhould be tranſplanted out into Nurſery-beds, where they may remain two Years longer; by which Time they will have arriv'd at Strength to flower, and may then be remov'd to the ſeveral Places where they are to remain.

CLIMATE; [of Κλίμας, Gr. *an Inclination*] is a Part of the Surface of the Earth bounded by two Circles parallel to the Equator; ſo that the longeſt Day in that Parallel neareſt to the Pole, exceeds the longeſt Day in that Parallel neareſt to the Equator by ſome certain Space of Time, *viz.* half an Hour, till you come to Places ſituate nearly under the Artick Circle; and a whole Hour, or even ſeveral Days, when you go beyond it.

The antient *Greek* Geographers reckon'd only ſeven *Climates* from the Equator towards the North Pole, and denominated them from ſome noted Place, through which the middle Parallel of the *Climate* paſs'd: But the Moderns reckon up twenty-four.

The *Beginning* of the *Climate* is the Parallel Circle, wherein the Day is the ſhorteſt.

The *End* of the *Climate* is that wherein the Day is the longeſt.

The *Climates* therefore are reckon'd from the Equator to the Pole; and are ſo many Bands or Zones, terminated by Lines parallel to the Equator; tho' in Strictneſs there are ſeveral *Climates* in the Breadth of one Zone.

Each *Climate* only differs from its contiguous ones, in that the longeſt Day in Summer is longer or ſhorter by half an Hour in the one Place than the other.

As the *Climates* commence from the Equator, the firſt *Climate* at its Beginning has its longeſt Day preciſely twelve Hours long; at its End twelve Hours and an half: The ſecond, which begins where the firſt ends, *viz.* at twelve Hours and an half, ends at thirteen Hours: And ſo of the reſt, as far as the Polar Circles.

Here what Geographers call *Hour Climates* terminate, and *Month Climates* commence.

As an *Hour Climate* is a Space compriz'd between two Parallels of the Equator, in the firſt of which the longeſt Day exceeds that in the latter by half an Hour; ſo the *Month Climate* is a Space between two Circles parallel to the Polar Circles, whoſe longeſt Day is longer or ſhorter than that of its contiguous one by a Month or thirty Days.

The Antients, who confin'd the *Climates* to what they imagin'd the habitable Part of the Earth, only allow'd of ſeven, as has been ſaid: The firſt they made to paſs through *Meroe*, the ſecond through *Sienna*, the third through *Alexandria*, the fourth through *Rhodes*, the fifth through *Rome*, the ſixth through *Pontus*, and the ſeventh through the Mouth of the *Boriſthenes*.

The Moderns, who have ſail'd farther towards the Poles, make thirty *Climates* on each Side; and becauſe the Obliquity of the Sphere makes a little Difference in the Length of the longeſt Day, ſome of them make the Difference of the *Climates* but a Quarter of an Hour inſtead of Half an Hour.

The Term *Climate* is vulgarly beſtow'd on any Country or Region differing from another, either in reſpect of the Seaſons, the Quality of the Soil, or even the Manners of the Inhabitants, without any Regard to the Length of the longeſt Day.

CLINOPODIUM; [Κλινοπόδιον, of Κλίνη a *Bed*, and ποῦς, Gr. a *Foot*, as tho' the Feet of a Bed, becauſe (according to *Dioſcorides*) the Stalks of this Plant reſemble the Feet of a Bed.] Field-Baſil.

The *Characters* are;

It is a Plant with a labiated Flower, conſiſting of one Leaf, whoſe upper Lip is upright, roundiſh, and generally ſplit in two; but the Beard, or under Lip, is divided into three Segments; theſe Flowers are diſpos'd in Whorles round the Stalks, and are ſucceeded by oblong Seeds.

The *Species* are;

1. Clinopodium *origano ſimile, elatius, majore flore. C. B.* The taller Field-Baſil, with a large Flower reſembling Baſtard-Marjoram.

2. Clinopodium *origano ſimile, flore albo. C. B.* Field-Baſil, with a white Flower, reſembling Baſtard-Marjoram.

3. Clinopodium *arvenſe, ocymi facie. C. B.* Wild Field-Baſil, reſembling Baſil.

4. Clinopodium *Alpinum, roſeum, ſatureiæ foliis. Boc. Muſſ. Alpine* Field-Baſil, with Leaves like Savory.

5. Clinopodium *Virginianum, anguſtifolium, floribus amplis luteis purpureo-maculatis, cujus caulis, ſub quovis verticillo, decem vel duodecim foliolis rubentibus eſt circumcinctus. Baniſter. Pluk. Phyt. Tab.* 24. Narrow-leav'd *Virginian* Field-Baſil, with large yellow Flowers ſpotted with Purple.

The firſt Sort grows wild upon dry chalky Hills in divers Parts of *England*. The ſecond is a Variety of the firſt, from which it only differs in the Colour of the Flower. Theſe Sorts do abide many Years, and may be propagated in a Garden, by either ſowing their Seeds, or parting of their Roots; the latter of which is the moſt expeditious Method, as alſo the ſureſt Way to preſerve the white-flowering Kind in its Colour, becauſe it may return back to the purple Kind from which it at firſt degenerated. Theſe Plants ſhould have a light Soil, and an open Situation, in which they will thrive exceedingly.

The third Sort is alſo found upon very ſtony or gravelly Hills in ſeveral Parts of *England*; but this being an annual Plant, is only propagated by Seeds, which ſhould be ſown ſoon after they are ripe, otherwiſe they will hardly grow: This muſt have a very poor ſtony Soil, in which it chiefly delights.

The fourth Sort is alſo an annual Plant, which was brought from the *Alps*: This ſhould be ſown in the Spring of the Year, in almoſt any Soil, it being a very good-natur'd Plant, and will thrive in any Part of the Garden.

The fifth Sort grows wild in *Virginia* and *Carolina*, from whence the Seeds have been ſent over, which grow very well with us, and are hardy enough to reſiſt our Cold in the open Air, if planted in a dry Soil.

CLUTIA.

This Plant was named by the learned Dr. *Boerhaave* of *Leyden*, in Memory of *Augerius Clute*, who was a curious Botaniſt.

The *Characters* are;

It hath a roſe-ſhaped Flower, conſiſting of five Leaves; in the Center ariſes the Pointal, ſurrounded by five Stamina: this Pointal afterward becomes the Fruit, which is divided into three Parts, and hath three Cells, in which are contained Seeds.

We have but one *Species* of this Plant, which is,

Clutia *Æthiopica fruteſcens, portulacæ folio, flore ex albido vireſcente. Boerh.* Shrubby *Æthiopian* Clutia, with a Purſlane Leaf, and a greeniſh white Flower.

This Plant is propagated by Seeds, which ſhould be ſown early in the Spring, on a moderate Hot-bed, obſerving to water the Bed gently from time to time, as the Surface becomes dry; and in the Heat of the Day the Glaſſes ſhould be raiſed to admit freſh Air, and let the Steam ariſing from the Bed to paſs off. If the Bed be of a proper Temper for Heat, the Plants will appear in about a Month after ſowing; and when they are about two Inches high, they ſhould be carefully taken up, and tranſplanted each into a ſeparate ſmall Pot filled with light freſh Earth, and plunged into a Hot-bed of Tanners-bark, obſerving to ſhade them until they have taken new Root; after which time they ſhould be frequently refreſhed with Water, and the Glaſſes ſhould be raiſed every Day, when the Weather is warm, to admit freſh Air; otherwiſe the Plants will draw up very tall, and become very weak. Toward the latter End of *June*, if the Plants have made a good Progreſs, they will be near a Foot in Height: therefore you ſhould then begin to inure them to bear the open Air; and the middle of *July*, they may be removed out of the Hot-bed, and placed in the open Air, in a warm Situation, where they may be defended from ſtrong Winds. During the Summer Seaſon, theſe Plants muſt be frequently watered; but it ſhould not be given in too large Quantities, eſpecially while the Plants are young. Toward the latter End of *September*, the Plants muſt be removed into Shelter; for if they are expoſed too late in Autumn, they will be in Danger of ſuffering by Morning Froſts. In Winter theſe Plants ſhould be placed in a moderate Stove for the firſt Seaſon, while they are young; but after they have obtained Strength, they will live in a good Green-houſe; but then they ſhould not have too much Water in cold Weather. This Plant will riſe to the Height of three or four Feet, and become ſhrubby; and being an Ever-green, will add to the Variety in the Green-houſe.

CLYMENUM; [*κλύμενον*, of *κυλίνδω*, Gr. *to roll*, becauſe the Branches of this Plant embrace whatever Plants do grow near them with their Tendrils.] Chickling-Vetch.

The *Characters* are;

The Stalks, Flowers, and Fruits of this Plant are like thoſe of Lathyrus; *but the Leaves conſiſt of many Conjugations plac'd on a Mid-rib, which ends in a Tendril.*

The *Species* are;

1. Clymenum *Hiſpanicum, flore vario, ſiliqua plana. Tourn.* *Spaniſh* Chickling-Vetch, with a variable Flower, and a plain Pod.
2. Clymenum *Hiſpanicum, flore vario, ſiliqua articulata. Tourn.* *Spaniſh* Chickling-Vetch, with a variable Flower, and a jointed Pod.
3. Clymenum *Bithynicum, ſiliqua ſingulari, flore minore. Jeſſieu.* *Bithynian* Chickling-Vetch, with a ſingle Pod, and ſmaller Flower.
4. Clymenum *Pariſienſe, flore cæruleo. Tourn.* Common Chickling-Vetch, with a blue Flower.
5. Clymenum *Græcum, flore maximo ſingulari. T. Cor.* *Greek* Chickling-Vetch, with a large ſingle Flower.

The firſt, ſecond, third, and fifth Sorts are Annuals, and muſt be ſown every Year, (as is practis'd for the *Sweet-Pea*): If they are ſown in *Auguſt*, in a warm Border, they will ſtand through the Winter, and flower early in the ſucceeding Spring, by which Method you may be ſure to obtain good Seeds; whereas thoſe which are ſown in the Spring, are many times deſtroy'd by the Rains in Autumn before their Seeds are perfected. Theſe Plants delight in a dry Soil, and an open Situation; for if they are over-hung by Trees, *&c.* they ſeldom come to any Perfection.

Thoſe of theſe Plants which are ſown in Autumn, will begin to flower in *May*, and continue to produce new Flowers till *July*; about which Time the Seeds of their early Flowers will be perfected. Their Flowers are in Shape like thoſe of the *Pea*: but being of variable Colours do make a pretty Variety in a Garden; and if the Plants are ſupported with Sticks, they may be kept in a ſmall Compaſs. The fourth Sort hath a perennial Root, which multiplies very faſt, ſoon over-running a Spot of Ground, and ſhould therefore be kept in a Pot, where the Roots will be confin'd, and thereby the Plant caus'd to produce a greater Quantity of Flowers than it would naturally do if its Roots had full Liberty.

CNICUS.

The *Characters* are;

It hath floſculous Flowers, conſiſting of many Florets, which are multifid, and ſtand upon the Embryo; the Florets are inclos'd in a ſcaly Cup ſurrounded with Leaves.

The *Species* are;

1. Cnicus *ſylveſtris hirſutior, ſive Carduus Benedictus. C. B.* The Bleſſed Thiſtle, *vulgo.*
2. Cnicus *atractylis lutea dictus. H. L.* The yellow Diſtaff-Thiſtle, *vulgo.*
3. Cnicus *perennis cæruleus Tingitanus. H. L.* *Tangier* perennial blue Diſtaff-Thiſtle.
4. Cnicus *Creticus, atractylidis folio & facie, flore leucophæo. T. Cor.* *Candia* Diſtaff-Thiſtle, with whitiſh Flowers.
5. Cnicus *Hiſpanicus arboreſcens fœtidiſſimus. Tourn.* Stinking *Spaniſh* Tree Diſtaff-Thiſtle.

The *Bleſſed Thiſtle* is cultivated in Gardens for the Herb, which is dry'd and preſerv'd for medicinal Uſes; but of late Years it hath been in leſs Uſe than formerly, for which Reaſon there is but little of it now propagated.

This being an annual Plant, is only rais'd by Seeds, which ſhould be ſown in Autumn, or very early in the Spring: When the Plants are come up, they ſhould be either tranſplanted, or hough'd out to about nine or ten Inches Diſtance from each other, that the Plants may have Room to ſpread, obſerving alſo to keep them clear from Weeds; and when the Plants are in full Flower, they ſhould be cut off and laid to dry in a ſhady Place; and after they are thoroughly dry, they may be tied up into Bundles, and hung up in a dry Room upon Strings in Rows, ſo that the Air may paſs freely between them, which will prevent their growing mouldy or rotting, which they are very ſubject to, if laid too cloſe, or kept in a moiſt Place.

The other Varieties are only preſerv'd in curious Botanick Gardens; they may be propagated by ſowing their Seeds in the Spring, in a warm dry Soil, and the Plants reduc'd to about two Feet Diſtance: They will flower in *July*; and if the Autumn is favourable, their Seeds will be perfected in *September*.

COA. This Plant was ſo named by Father *Plumier* from the Iſland of *Cous*, which gave Birth to the Prince of Phyſicians *Hippocrates*. We have no *Engliſh* Name for this Plant.

The *Characters* are;

It hath a globular bell-ſhaped Flower, conſiſting of one Leaf; from whoſe Cup ariſes a multifid Pointal, fixed like a Nail in the hinder Part of the Flower; which afterward becomes a Fruit, compoſed of three membranaceous Seed-veſſels, which are compreſſed, bivalve, and divided into two Cells, in which are contained oblong winged Seeds.

We have but one *Species* of this Plant, which is;

Coa *ſcandens, fructu trigemino ſubrotundo. Plum.* Climbing Coa, with a roundiſh Fruit, which opens into three Parts.

This Plant was obſerved by Father *Plumier* (in the *French* Iſlands in *America*) and hath been ſince found in great Plenty in the *Spaniſh* Settlements in *America*, particularly about *Campechy*, from whence the Seeds have been ſet by Mr. *Robert Millar*, Surgeon, to ſome curious Perſons in this Country, who have raiſed ſeveral of the Plants; but as they are very young, ſo it can't be expected that any of them will produce Flowers until they are three or four Years old, becauſe they ſeem to be of ſlow Growth.

This Plant is propagated by Seeds, which muſt be obtained from the Places where it naturally grows, which ſhould be ſown early in the Spring, in ſmall Pots filled with light freſh Earth, and plunged into a Hot-bed of Tanners-bark, obſerving to water the Earth as often as it becomes dry; and in the Heat of the Day, the Glaſſes of the Hot-bed ſhould be raiſed to admit freſh Air, and let the Steam, which may ariſe from the Bed, paſs off; and if the Nights ſhould prove cold, the Glaſſes ſhould be covered with Mats. If this be duly obſerved, the Plants will begin to appear in three Weeks or a Month after ſowing; when you ſhould be careful to ſprinkle them frequently with Water, but do not let them have too much at each Time; for while they are very young, they will be in danger of rotting, if they are kept too moiſt. You muſt alſo obſerve to admit freſh Air to them, in proportion to the Warmth of the Seaſon, otherwiſe they will draw up very weak; which ſhould always be carefully prevented, becauſe few Plants which are drawn up tender at firſt, will ever after become ſo ſtrong and beautiful as thoſe which are brought up hardily from the Beginning.

When the Plants are about two Inches high, they ſhould be carefully tranſplanted each into a ſeparate Pot, filled with light freſh Earth, and plunged into the Hot-bed again, obſerving to ſhade the Glaſſes every Day when the Sun is warm, until the Plants have taken new Root; after which Time they ſhould be raiſed every Day to admit freſh Air to the Plants, in proportion to the Warmth of the Seaſon. During the Summer Seaſon, theſe Plants muſt be frequently refreſhed with Water; and when their Roots have filled the Pots in which they were firſt planted, they ſhould be ſhaken out of them, and their Roots pared round, and then put into Pots a little larger than the former, which muſt be filled with light freſh rich Earth, and then plunged again into the Hot-bed; for theſe Plants will not live in the open Air in this Country : ſo that when they are grown too large to remain under the Glaſſes of the Hot-bed, they ſhould be removed into the Bark Stove, where they ſhould be placed with the tendereſt Exoticks, and heated with great Care. This Plant commonly riſes to the Height of five or ſix Feet, but being a trailing Plant muſt be ſupported by a Stake ; otherwiſe it will trail on the neighbouring Plants in the Stove, and injure them. It is ever-green, and the Leaves being of a ſhining green Colour, it makes a pretty Variety amongſt other tender exotick Plants.

COAST-MARY. *Vide* Balſamita.

COCCIGRIA. *Vide* Cotinus Coriaria.

COCHLEARIA ; [is ſo call'd of *Cochleare*, Lat. a *Spoon* ; becauſe the Leaves of this Plant are hollow'd like a Spoon.] Spoon-wort, or Scurvy-graſs.

The *Characters* are ;

The Flower conſiſts of four Leaves, which are diſpos'd in Form of a Croſs ; from the Flower-cup ariſes the Pointal, which becomes an almoſt globular Fruit, divided into two Cells by an intermediate Partition, to which the Valves adhere on both Sides, and are furniſh'd with many round Seeds.

The *Species* are ;

1. Cochlearia *folio ſubrotundo. C. B.* Scurvy-graſs with a roundiſh Leaf, or Common Scurvy-graſs.
2. Cochlearia *folio ſinuato. C. B.* Scurvy-graſs with a ſinuated Leaf, or Sea Scurvy-graſs, *vulgo.*
3. Cochlearia *minima, ex montibus Walliæ. Sher. Boerh. Ind.* The leaſt Scurvy-graſs, from the *Welſh* Mountains.
4. Cochlearia *folio cubitali. Tourn.* Horſe-radiſh, *vulgo.*

The firſt of theſe *Species* is propagated in Gardens for medicinal Uſes : This is done by ſowing the Seeds in *July*, ſoon after they are ripe, in a moiſt ſhady Spot of Ground ; and when the Plants are come up, they ſhould be thinn'd ſo as to be left at about four Inches Diſtance each way. The Plants that are taken out may be tranſplanted into other ſhady Borders, if you have Occaſion for them ; otherwiſe they may be hough'd out, (as is practis'd for *Onions*, *Carrots*, &c.) and at the ſame time all the Weeds may be hough'd down, ſo as to clear the Plants intirely from Weeds, that they may have Room to grow ſtrong. In the Spring theſe Plants will be fit for Uſe ; and thoſe that are ſuffer'd to remain will run up to Seed in *May*, and perfect their Seeds in *July*. If this Plant is ſown in the Spring, the Seeds ſeldom grow well ; therefore the beſt Time is ſoon after they are ripe : The Plants rarely live after producing Seeds ; ſo that it ſhould be ſown every Year, to have it for Uſe.

The *Sea Scurvy-graſs* is alſo us'd in Medicine ; but this grows in the Salt Marſhes in *Kent* and *Eſſex*, where the Salt Water overflows it almoſt every Tide ; and can rarely be made to grow in a Garden, or at leaſt to laſt longer there than one Year : But it being ſo eaſily gather'd in the Places before-mention'd, the Markets are ſupply'd from thence by the Herb-women, who make it their Buſineſs to gather this Herb.

The little *Welſh Scurvy-graſs* is an abiding Plant, and may be preſerv'd in a Garden, if planted in a ſtrong Soil, and a ſhady Situation. This is preſerv'd in curious Gardens of Plants, but is not of any Uſe.

The *Horſe-Radiſh* is propagated from Cuttings or Buds from the Sides of the old Roots. The beſt Seaſon for this Work is in *October* or *February* ; the former for dry Lands, and the latter for moiſt. The Manner of doing it is as follows : Provide yourſelf with a good Quantity of Off-ſets, which ſhould have a Bud upon their Crowns : but it matters not how ſhort they are ; therefore the Upper-part of the Roots which are taken up for Uſe, ſhould be cut off about two Inches long with the Bud to it, which is eſteem'd the beſt for planting. Then make a Trench ten Inches deep, in which you ſhould place the Off-ſets at about four or five Inches Diſtance each Way with the Bud upwards, covering them up with the Mould that was taken out of the Trench : Then proceed to a ſecond Trench in like manner, and continue the ſame until the whole Spot of Ground is planted. After this, level the Surface of the Ground even, obſerving to keep it clear from Weeds, until the Plants are ſo far advanced as to be ſtrong enough to over-bear and keep down the Weeds. With this Management, the Roots of the *Horſe-Radiſh* will be long and ſtrait, and free from ſmall lateral Roots ; and the ſecond Year after planting will be fit for Uſe. 'Tis true, they may be taken up the firſt Year ; but then the Roots will be but ſlender ; therefore it is the better way to let them remain until the ſecond Year. The Ground in which this is planted ought to be very rich, otherwiſe the Roots will make but a ſmall Progreſs.

COCOS. *Vide* Palma Nucifera.

CODLIN-TREE. *Vide* Malus or Apple-tree.

COFFEE-TREE. *Vide* Jaſminum.

COLCHICUM, is ſo call'd, from *Colchis* a Province of the *Levant*, (now call'd *Mingrelia*) becauſe this Plant was formerly very common in that Place.

The *Characters* are ;

It hath a Flower conſiſting of one Leaf, which is ſhap'd like a Lily, riſing from the Root in Form of a ſmall Tube, and is widened gradually into ſix Segments ; the Pointal riſes from the Bottom of the Flower, ending in ſmall Threads, and turns to an oblong triangular Fruit, divided into three Cells, which are full of roundiſh Seeds : It hath alſo a ſolid bulbous Root, which is cover'd with a membranous Skin.

The *Species* are ;

1. Colchicum *commune. C. B.* Common Meadow-Saffron.
2. Colchicum *Anglicum album. Park. Engliſh* white Meadow-Saffron.
3. Colchicum *pleno flore. C. B.* The double-flower'd Meadow-Saffron.
4. Colchicum *floribus Fritillariæ inſtar teſſelatis, foliis planis. M. H.* Meadow-Saffron with Flowers chequer'd like thoſe of the *Fritillaria*, and ſmooth Leaves.
5. Colchicum *Chionenſe, floribus Fritillariæ inſtar teſſelatis, foliis undulatis. M. H.* Meadow-Saffron with chequer'd Flowers, and wav'd Leaves, *commonly call'd* Colchicum *Chio.*
6. Colchicum *latifolium variegatum. C. B.* Broad-leav'd ſtrip'd Meadow-Saffron.
7. Colchicum *vernum Hiſpanicum. C. B.* Spring-flowering Meadow-Suffron.
8. Colchicum *candidum multiflorum. C. B.* Many-flower'd white Meadow-Saffron.

The firſt of theſe Species is found in moiſt Meadows in ſeveral Parts of *England*. The ſecond is a Variety of the firſt, from which it only differs in the Colour of the Flower. The third Sort alſo originally came from the firſt ; but is preſerv'd in Gardens, for the Doubleneſs of its Flowers. The fourth Sort is a Stranger to our Iſland, and is ſuppos'd to have been brought from the *Levant*, with the fifth Sort, which differs from the fourth in having the green Leaves very much waved on the Edges. The Root of one of theſe two Species is thought to be the *Hermodactyl* of the Shops. The ſixth Sort hath fine, broad, variegated, green Leaves, for which it is greatly eſteem'd. The ſeventh Sort is valuable for producing its Flowers early in the Spring ; as is the eighth for producing a great Number of Flowers.

Theſe are all very pretty Varieties for a Flower-Garden, moſt of them producing their Flowers in Autumn, when few other Plants are in Beauty. The Flowers come up and are blown ſome time before the green Leaves appear, and are therefore by ſome call'd *Naked Ladies*. The green Leaves come up in Winter, and in Spring are extended to a great Length : In *May* the green Leaves begin to decay ; ſoon after which Time, is the proper Seaſon to tranſplant their Roots ; for if they are ſuffer'd to remain in the Ground till *Auguſt*, they will ſend forth freſh Fibres ; after which Time it will be too late to remove them. The Roots may be kept above Ground until the Middle of *Auguſt* ; at which Time if they are not planted, they will produce their Flowers as they lie out of the Ground : but this will greatly weaken their Roots. The Manner of planting their Roots being the ſame as *Tulips*, &c. I ſhall forbear mentioning it here, referring the Reader to that Article : And alſo for ſowing the Seeds, by which Means new Varieties may be obtain'd, I ſhall refer to the Article of *Xyphion*, where there will be proper Directions for this Work.

COLD, ſignifies ſomething devoid of *Heat*, or which does not contain in it any Particles of Fire ; according to which Definition, Cold is a mere Negative Term. And this is agreeable to the Sentiments of moſt of our Modern Philoſophers, who ſuppoſe *Cold* to conſiſt in a mere Privation or Diminution of *Heat*.

Others, much on the ſame Principle, define *Cold* to be that State of the minute Parts of a Body, wherein they are agitated more ſlowly and faintly than thoſe of the Organs of *Feeling*. And in this Senſe *Cold* is a mere Term of Relation: And hence the ſame Body becomes liable to be perceiv'd *Hot* or *Cold*, as the Particles of it are in greater or leſſer Degree of Motion than thoſe of the ſenſible Organ.

Heat is ſuppos'd to conſiſt in a particular Motion of the Parts of the *Hot* Body: And hence the Nature of *Cold*, which is its Oppoſite, is eaſily deducible; for we find that *Cold* extinguiſhes, or rather abates *Heat*. Whence it ſeems to follow, that thoſe Bodies are *Cold* which check and reſtrain the Motion of the Particles wherein *Heat* conſiſts.

There are three Kinds of Bodies that can do this, *viz.* either thoſe whoſe Particles are perfectly at Reſt; or thoſe whoſe Particles are indeed agitated, but with leſs Violence than thoſe of the Hot Body to which they are apply'd; or, laſtly, ſuch whoſe Particles have a Motion proper for exciting the Senſation of *Heat*, but move with a different Determination, ſo as to retard and change the Motion of the Particles of the Organ.

Hence three different Kinds of *Cold*, or *cold Bodies* do proceed.

The 1ſt, That *Cold* is common to all hard Bodies which conſiſts in the Reſt of their Parts.

The 2d, Is that which riſes from plunging any Part of the Body in Water; which conſiſts in this, that the Parts of our *Præcordia* being more briſkly agitated than thoſe of the *Fluid*, do communicate part of their Motion to it.

The 3d, The *Cold* felt on the Collection of warm Air with a Pan, or in blowing hot Breath out of our Mouth with the Lips cloſe ſhut; which conſiſts in this, that the direct Motion of the Particles of *Air* do in ſome Meaſure change and rebate the Motion and Determination of the Parts of the Body: And hence it is that a *cold* Body cannot cool another without heating itſelf.

Hence alſo it proceeds, that the more the Parts of a *frigid* Body are at Reſt, the more the Particles of a warm Body that is apply'd to heat them, muſt loſe of their Motion, and conſequently of their Heat.

Thus there being more quieſcent Parts in a Marble than in Wood, which is full of Pores and Interſtices, the Marble is felt colder than the Wood. And hence alſo we may underſtand why *Air* near Marble and other denſe Bodies feels ſomewhat colder than in other Places.

On this Principle the two latter Kinds of *Cold* appear ſomewhat more than Privations: The Particles inducing the *Cold* may be eſteem'd real frigorick Corpuſcles; and *Coldneſs* may be deem'd a real Quality, as well as *Hotneſs*. Theſe Particles do not only check the Agitation of thoſe continually diffus'd from the Inner Parts of an Animal to the Outer; but having an elaſtick Power, they bend and hang about the Filaments of the Body, pinch and ſqueeze them; and hence is that acute pungent Senſation call'd *Cold*.

That *Cold* is more than a mere Relation or Compariſon, is evident from its having real and poſitive Effects; ſuch as *Freezing*, *Congelation*, *Condenſation*, *Rarefaction*, *Burſting*, &c.

Dr. *Clark* takes *Cold* to be owing to certain Nitrous and other Saline Particles, endued with particular Figures proper to produce ſuch Effects. Hence *Sal-Armoniack*, *Salt-Petre*, *Salt of Urine*, and many other *Volatile* and *Alkalizate Salts*, mix'd with *Water*, increaſe its Degree of *Cold* very ſenſibly.

Hence alſo comes that popular Obſervation, That *Cold* prevents Corruption. Which, however, muſt not be admitted without an Exception: Since if a hard porous Body have its Interſtices fill'd with Water, and this be too much dilated by freezing, the including Body will be burſt. And thus it is that *Cold* proves deſtructive to the Parts of ſome *Plants*: As it happen'd in the Winter *Anno* 1728, when in ſeveral Trees, whoſe Trunks were much expos'd to the South-Weſt, the Sap being thereby rarefy'd by the Warmth of the Sun, which for ſeveral Days at the Beginning of the ſevere Froſt, ſhone with an uncommon Heat, and the Nights coming on to extreme Cold, whereby the rarefy'd Sap was ſo ſuddenly condens'd, that the Sap-Veſſels could not contain it, and thereby burſt off the Bark of many Trees almoſt from Top to Bottom, and this chiefly on the South-Weſt Side of the Trees, as it did of two large Occidental *Plane-Trees* in the Phyſick-Garden at *Chelſea*, and ſeveral *Pear* and other *Fruit-Trees* in the Nurſeries of Mr. *Francis Hunt* at *Putney*.

Dr. *Boerhaave* ſays, That there is no ſuch Thing in all Nature as abſolute *Cold*; that the moſt ſevere he had ever known, was in the Year 1728, that then the Water would freeze while it ran down his Hand; and yet even then the *Cold* was not ſo complete, but that he could make an artificial *Cold* greater by twelve Degrees.

Tho' much might be ſaid as to the Effects of *Cold* on Plants, I ſhall only conclude with the Obſervation of the Reverend Dr. *Hales*, who in the Concluſion of his excellent Treatiſe of *Vegetable Staticks*, ſays;

The conſiderable Quantity of Moiſture, which is perſpir'd from the Branches of Trees during the cold Winter-ſeaſon, plainly ſhews the Reaſon, why in a long Seaſon of cold North-Eaſterly Winds, the Bloſſoms and tender young-ſet Fruit and Leaves are, in the early Spring, ſo frequently blaſted, *viz.* by having the Moiſture exhaled faſter than can be ſupply'd from the Trees; for doubtleſs Moiſture riſes ſlower from the Root, the colder the Seaſon is, tho' it riſes, in ſome Degree all the Winter; as is evident, as he ſays, from his ſixteenth Experiment in the ſaid Book.

And from the ſame Cauſe it is, that the leafy Spires of Corn are by theſe cold drying Winds often faded and turn'd yellow, which makes the Huſbandman, on theſe Occaſions, wiſh for Snow; which, though it be very cold, yet it not only defends the Root from being frozen, but alſo ſcreens the Corn from theſe drying Winds, and keeps it in a moiſt, florid, ſupple State.

It ſeems therefore to be a reaſonable Direction, which ſome Authors who write on Agriculture and Gardening, give, *viz.* during theſe cold drying Winds, when little Dew falls, to water the Trees in dry Soils, in the bloſſoming Seaſon, and while the young-ſet Fruit is tender; and provided there is no immediate Danger of a Froſt, or in Caſe of continu'd Froſt, to take care to cover the Trees well, and at the ſame Time to ſprinkle them with Water, which is imitating Nature's Method of watering every Part.

As to ſloping Shelters over Wall-trees, he ſays: I have often found, that when they are ſo broad as to prevent any Rain or Dew coming at the Trees, they do more Harm than Good in theſe long Eaſterly drying Winds, becauſe they prevent the Rain and Dews falling on them, which would not only refreſh and ſupple them, but alſo convey Nouriſhment to them: But in caſe of ſharp Froſt after a Shower of Rain, theſe Shelters and other Fences muſt needs be of excellent Uſe to prevent the almoſt total Deſtruction occaſion'd by the Freezing of the tender Parts of Vegetables, when they are full ſaturate with Moiſture.

COLEWORTS. *Vide* Braſſica.

COLOCYNTHIS; [Κολοκύνθη, of κοιλίαν κινεῖ *it moves the Belly*; or of κόλου κυῶν, *Dog's-meat*, by Way of Irony, becauſe of the great Bitterneſs.] Coloquintida or Bitter Gourd.

The *Characters* are;

It is in all reſpects like the Gourd, *excepting the Leaves of this Plant being deeply jagged, and the Fruit being exceſſively bitter, and not eatable.*

The *Species* are;

1. Colocynthis *fructu rotundo major. C. B.* The greater Coloquintida, with a round Fruit.
2. Colocynthis *fructu Aurantio ſimili. Tourn.* Coloquintida, with a Fruit reſembling an *Orange*.

There are ſeveral other Varieties of this Plant, which are very common in divers Parts of the *Eaſt* and *Weſt-Indies*; but as few of them come to any Maturity with us, ſo I ſhall paſs them over, with only obſerving, that whoever hath a mind to cultivate any of theſe Plants, muſt ſow them upon a Hot-bed, and manage them as is directed for raiſing Early *Cucumbers*; to which I ſhall refer the Reader.

COLUMBINE. *Vide* Aquilegia.

COLUTEA, Bladder-Sena.

The *Characters* are;

It hath a papilionaceous (or Butterfly) Flower, which is ſucceeded by Pods, ſomewhat reſembling the inflated Bladders of Fiſhes, in which are contain'd ſeveral Kidney-ſhap'd Seeds.

The *Species* are;

1. Colutea *veſicaria. C. B.* Bladder Sena.
2. Colutea *veſicaria, veſiculis rubentibus. J. B.* Bladder-Sena, with reddiſh-colour'd Pods.
3. Colutea *Orientalis, flore ſanguinei coloris, luteo maculâ notato. T. Cor.* Eaſtern Bladder Sena, with Blood-colour'd Flowers ſpotted with Yellow.
4. Colutea *Æthiopica, flore Phœnicio, foliis barbæ Jovis. Breyn. Cent.* *Ethiopian* Bladder-Sena, with Scarlet Flowers, and Leaves like the *Silver Buſh*.

5. Colutea *Africana annua, foliis parvis mucronatis, veſiculis compreſſis. Hort. Amſt. African* annual Bladder-Sena, with ſmall pointed Leaves and compreſs'd Pods.

The two firſt Sorts are promiſcuouſly ſold by the Gardeners near *London*, amongſt other flowering Shrubs, and are ſeldom diſtinguiſh'd but by *Botaniſts*.

Theſe are propagated by ſowing their Seeds any Time in the Spring, in a Bed of common Earth; and when the Plants are come up, they muſt be kept clear from Weeds; and the *Michaelmas* following, they ſhould be tranſplanted either into Nurſery Rows, or in the Places where they are deſign'd to remain; for if they are let grow in the Seed-bed too long, they are very ſubject to have downright Tap-roots, which renders them unfit for Tranſplantation: Nor ſhould theſe Trees be ſuffer'd to remain too long in the Nurſery before they are tranſplanted, for the ſame Reaſon.

Theſe Shrubs grow to the Height of eight or ten Feet, and are very proper to intermix with Trees of a middling Growth in Wilderneſs-quarters, or in Clumps of Flowering-trees, where the Oddneſs of their Flowers and Pods will make a pretty Variety.

The third Sort was brought from the *Levant* by Monſieur *Tournefort* to the King's *Garden* at *Paris*; from whence ſeveral curious Gardens have been ſupply'd with this beautiful Plant: This is alſo rais'd by ſowing the Seeds in the Spring, either in a moderate Hot-bed, or in a warm Border; and when the Plants are come up about four Inches high, they ſhould be tranſplanted into Pots fill'd with light freſh Earth, and during the firſt Winter ſhould be ſhelter'd under a common Hot-bed Frame; and the Spring following, they may be taken out of the Pots, and planted into a warm Border, where they will thrive and flower the third Year from Seed.

The fourth Sort is tenderer than any of the former, and ſhould be ſown on a Hot-bed, and afterwards tranſplanted into Pots, and manag'd as was directed for the third Sort, and in the Spring put into warm Borders under a good Wall, where it will flower and ſeed the ſecond Year; and if the Winters prove mild, will remain for two or three Years, producing great Quantities of beautiful Scarlet Flowers; but if the Winter proves hard, or the Soil is moiſt wherein it is planted, it ſeldom ſtands through a Winter abroad. This Plant is by moſt People preſerv'd in Green-houſes with *Oranges*, *Myrtle*, &c. But in this Management they are ſubject to grow very weak, for want of more free open Air than can be given with Safety to the other Trees; therefore the beſt Method is, to preſerve them, during the Winter, in an open Frame, where the Glaſſes may be kept off in mild Weather, and put on in froſty cold Nights, by which hardy Management the Plants will produce a greater Quantity of Flowers than when they are drawn in a Houſe.

The fifth Sort is an annual Plant, ſeldom riſing above three Feet high with us, and is but of very little Beauty: This is preſerv'd in curious Gardens of Plants. The Management of it being much the ſame as the *Balſamina*, I ſhall refer the Reader thereto for Inſtructions.

COLUTEA SCORPIOIDES. *Vide* Emerus.

COLLIFLOWER. *Vide* Braſſica.

COMA AUREA; [ſo call'd from the Golden Colour of its Flowers] Goldylocks.

The *Characters* are;

It hath a fibroſe perennial Root; the Leaves, which are in great Numbers, are produc'd alternately on every Side the Branches; the Cup of the Flower is not ſpecious; the Flowers are yellow, and produc'd either ſingly, or in an Umbel upon the Tops of the Branches, to which may be added, it hath the Appearance of a Shrub.

The *Species* are;

1. Coma Aurea *Germanica. Park. Theat. German* Goldylocks.

2. Coma Aurea *Africana, fruticans, foliis linariæ anguſtis major. Hort. Amſt. African* ſhrubby Goldylocks, with narrow Toad-Flax Leaves.

3. Coma Aurea *Africana, fruticans, foliis crithmi marini. Hort. Amſt. African* ſhrubby Goldylocks, with Samphire Leaves.

4. Coma Aurea *Africana, fruticans, foliis glaucis, & in extremitate trifidis. Hort. Amſt. African* ſhrubby Goldylocks, with Sea-green Leaves, which are divided into three Parts at their Extremities.

5. Coma Aurea *Africana, fruticans, foliis glaucis longis tenuibus multifidis, apice pinnularum trifido. Boerh. Ind. alt.* Shrubby *African* Goldylocks, with long narrow Sea-green Leaves, which are divided into many Parts, each of which are trifid at their Points.

The firſt of theſe Plants is very hardy, and will endure to be planted in the open Ground: This is propagated by parting the Roots in the Spring, or by planting Cuttings in any of the Summer Months, which if water'd and ſhaded will take Root in ſix Weeks Time, when they may be tranſplanted into the Borders where they are to remain for good: This Plant produces very pretty Umbels of Gold-colour'd Flowers upon the Tops of the Branches, which continue in Beauty for a long Time, which renders it worthy of a Place in every good Garden. The other four Sorts are tenderer, and muſt be preſerv'd either in a Green-houſe or under a Hot-bed Frame in Winter.

Theſe are propagated by planting their Cuttings in any of the Summer Months in a Bed of light Earth; which if kept ſhaded and watered, will take Root in two Months Time; when they muſt be planted into Pots fill'd with freſh light Earth, and may be expos'd to the open Air until *October*; at which Time they ſhould be remov'd to Shelter, leſt the Morning Froſts ſhould injure them: But they require to have a great Share of free open Air in mild Weather; for if they are ſhut up too cloſe they are very ſubject to Mouldineſs, and their younger Branches are very apt to decay: They muſt alſo have frequent, but moderate Waterings in Winter; and in the Spring, ſhould be remov'd into the open Air as ſoon as poſſible, obſerving to do it by degrees, that they may not receive a great Check thereby. With this Management theſe Plants will ſome of them grow to be eight or nine Feet high, and become very woody, and will produce great Quantities of Flowers thro' moſt Part of the Year, which renders them worthy of a Place in a good Green-houſe.

COMMELINA: This Plant was ſo call'd by Father *Plumier*, from Doctor *Commeline*, a famous Profeſſor of Botany at *Amſterdam*.

The *Characters* are;

The Leaves are produc'd alternately, and ſurround the Stalks at their Baſe, being in Shape ſomewhat like the Ephemeron; *the Stalks trail upon the Ground, and grow very branchy; at the ſetting on of the Branches, between the Wing of the Leaf and the Stalk, is produc'd a Flower which conſiſts of two Leaves, which are plac'd in the Form of two Wings, much after the manner of the* Butterfly Flowers; *From the upper Part of the Flower are produc'd three ſhort* Stamina *(or Threads); upon which are faſten'd yellow* Apices, *which reſemble the Head of a* Muſhroom: *In the under Part of the Flower are produc'd three other Male* Stamina, *which are thicker and longer than the other; the Ovary is produc'd in the Center of the Flower, which is extended into a long intorted Tube, and becomes an oblong Fruit, divided into two Cells, in each of which is contain'd one oblong Seed.*

There is but one *Species* of this Plant at preſent known, which is,

Commelina *graminea latifolia, flore cœruleo. Plum. Nov. Gen.* Broad Graſs-leav'd Herb Commeline, with blue Flowers.

This Plant ſeldom continues with us longer than one Year; but the Seeds, which are annually ripen'd, falling to the Ground, will grow again, ſo that we need be at no farther Trouble than to allot this Plant a Place in a warm Border, and not ſuffering it to be deſtroy'd, where it will maintain itſelf without any Culture. The Stalks of this Plant ſtriking Roots at the Joints as it lies upon the Ground, this Plant may be increas'd faſt enough in Summer by cutting theſe off, and tranſplanting them out into a freſh Spot of Ground, where they will greatly increaſe. The Seeds of this Plant ſhould be ſown as ſoon as it is ripe; for if it be kept till Spring, it ſeldom comes up well, nor will the Plants rais'd in the Spring be forward enough to produce ripe Seeds.

COMPARTIMENTS, are Beds, Plats, Borders, and Walks, laid out according to the Form of the Ground, and Ingenuity of the Artiſt, and depend more on a good Fancy than any Rules: Or, are Diverſities, or Knots of Flower-Gardens, or Parterres, of which there are great Variety, and may be diverſify'd infinitely, according to the Fancy of the Deſigner.

Plain Compartiments, are Pieces of Ground divided into equal Squares and Flower-Beds, mark'd out by the Line, of equal Length and Breadth.

Some Perſons allow to theſe Squares, Borders of two Feet in Breadth, and not more, if the Plat of Ground be ſmall; but if they be reaſonably large, three Feet; and they edge the Borders with *Box*, or upright hardy *Thyme*, or ſome other Aromatick *Herbs* or *Flowers*, for the Sake of the greater Neatneſs.

And in order to preſerve the Paths and Allies of *Compartiments* firm, even, and durable, they lay them with a Coat of Sand or Gravel two or three Inches thick, keeping them houghed and weeded as often as there ſhall be Occaſion.

COMPOSTS, [are ſo call'd, of *Compoſta*, or *Compoſita*, Lat. Compounds, of *componere*, Lat. to *compound* or *mix*: And in Huſbandry and Gardening, they ſignify ſeveral Sorts of Soils or Earthy Matter mix'd together, in order to make a Manure for aſſiſting the natural Earth in the Work of Vegetation, by Way of Amendment or Improvement.]

Compoſts are various, and ought to be different according to the different Nature or Quality of the Soils which they are deſign'd to meliorate, and according as the Land is either *light*, *ſandy*, or *looſe* or *heavy*, *clayey* and *cloddy*. A light, looſe Land requires a *Compoſt* of a heavy Nature, as the Scouring of deep Ditches, Ponds, *&c*.

So, on the other hand, a Land that is *heavy*, *clayey* or *cloddy*, requires a *Compoſt* of a more ſprightly and fiery Nature, that will inſinuate itſelf into the lumpiſh Clods; which, if they were not thus manag'd, would very much obſtruct the Work of Vegetation.

As a good *Compoſt* for *cold clayey* Land, ſome adviſe to take one Load of Sea-ſand, (if it can be conveniently had), or if not, other Sand, or ſandy Ground, or ſharp Sand, and two Loads of good rotten Dung, and three Loads of natural Mould, two Loads of the top Spit Turf from off the Meadows, or any other Kind of rich Turf Land, and half a Load of Coal-Aſhes, or the Sweepings of Streets, a ſmall Sprinkling of Pigeons, Sheep, or other hot Dungs. Theſe are to be laid down in different Heaps in a Circle, having a large Space in the Center, ſo that they may all be thrown up together in one Heap, which is to be done by as many Perſons at each Heap, as there are different Loads in each, *viz.* one to that of one Load, two to that of two Loads, and three to that of three Loads, and ſo on; theſe muſt caſt and ſpread at the ſame Time every Parcel with Care, and not all together in Lumps.

The fitteſt Time for the doing of this, is when the Weather is dry, and alſo in the Month of *May*. This Mixture ſhould be turn'd once a Month till *Michaelmas*, and then it may be ſcreen'd and ſeparated into ſeveral Sorts, to be ready, as occaſion ſhall require, in the Nurſery.

For the firſt Sort, it will be beſt to ſet the Skreen more upright; and what comes thro' may be mix'd with one fourth part of Melon Earth very fine.

The ſecond Sort may be ſcreen'd with the Skreen ſtanding more ſloping; by which means, what comes thro' will be coarſer than the firſt.

The Remainder, which will be the rougheſt and moſt cloddy Earth, is recommended as an extraordinary Manure to be dug in order to improve any barren or poor Land; and if it be kept in a Heap for one Year, and ſkreen'd the next Year, 'twill then be as good as either of the former. The fineſt of theſe ſhould be beſt kept in a Houſe, or under ſome Covering, that it may be dry; tho' it would be better to be turn'd out ſometimes to get Rain.

A *Compoſt* for a *looſe ſandy* Ground may be made by taking two Loads of Dung, three Loads of natural Soil, three Loads of ſtrong loamy Earth, three Loads of Pond Earth, or of the Scouring of Ditches, which are to be order'd, mix'd, and ſkreen'd as before; and ſo to make three different Sorts of Skreenings.

Others recommend other *Compoſts* differing according to the different Soils.

For a *ſtiff Soil* inclining to *Clay*, To make five Loads of the ſame Soil well broken and open'd, and to add to that five Loads more of Heath Turfs burnt; that theſe having been well mix'd and laid together during the Winter in a Heap or Ridge, and being well ſifted or ſkreen'd, are recommended as a good *Compoſt* that will extremely forward Trees.

2. To mix four Loads of ſharp Sand, and two Loads of Aſhes of burnt Furzes, Gorz, Fern, Weeds, or Wood, with four Loads of *ſtiff Soil* well broken and open'd: That theſe having been well mix'd together and laid up in a Ridge in *September*, ſhould lie till the *February* following, and then may be ſkreen'd and ſifted for Uſe. Sir *William Bruce* is ſaid to have uſ'd this *Compoſt* in his Garden with good Succeſs.

3. For a *ſtiff Soil*, Take four Loads of the ſtiff Soil, two Loads of rotten Wood, ſuch as may be found under a Wood Pile, or the ſame Quantity of rotted Leaves, if the former can't be had, two Loads of burnt Graſs-Turf, and four Loads of Sand: This is recommended to be done in *October* likewiſe; becauſe being then made, and ſifted in the following Spring, 'twill be better than if they were made in the Spring; for that the Heat of the Summer would exhale the volatile Spirits, and if they were not laid in ſome ſhady Place under Trees, the Weeds would exhauſt good Part of the Nouriſhment that is in them. Theſe being mix'd well, and laid in a Ridge till *February*, and then ſifted, is recommended as a good *Compoſt*.

4. Take two Loads of ſtiff Soil, two Loads of Rape-ſeed after the Oil has been preſs'd out, four Loads of Sand, and two Loads of burnt Heath or Graſs-Turf, and prepare them as the others, and ſift them: And this *Compoſt* is recommended as one that will forward any Plant.

5. Take four Loads of ſtiff Soil, two Loads of Malt Grains after Brewing, and four Loads of Sand; theſe being prepar'd as before, are recommended as a *Compoſt* that will haſten the Growth of Plants.

6. Take of Sheeps-dung and Wood-Aſhes equal Quantities; of Loam or Mother-Earth double the Quantity: Prepare them as before directed, and they will prove a good *Compoſt*.

7. Take four Loads of ſtiff Earth, four Loads of Sand, four Loads of Horſe-Dung well conſum'd, and two Loads of Turf-Aſhes: Prepare this Mixture as before directed.

The other *Compoſitions* which are proper for particular Plants, or choice Flowers, being exhibited in the ſeveral Articles where thoſe Plants are treated of, I ſhall not repeat them in this Place, but refer the Reader thereto.

COMPOUND FLOWERS, are ſuch as conſiſt of many Florets or Semi-florets, or both together, which make up what is commonly call'd one whole Flower.

CONE: A *Cone* is a hard dry Seed-Veſſel of a conical Figure, conſiſting of ſeveral Woody Parts (and is for the moſt part ſcaly) adhering cloſely together, and ſeparating when ripe.

CONIFEROUS TREES, are ſuch as bear *Cones*; as, the *Cedar of Libanon*, *Fir*, *Pine*, &c.

CONOCARPODENDRON, Silver Tree, *vulgo*.

The *Characters* are;

It hath an apetalous ſtamineous Flower, which is ſurrounded by a Number of long Leaves, immediately under the Flower-cup, which conſiſts of five narrow Leaves; theſe are ſucceeded by Cones, in Shape like thoſe of the Larch Tree; the Seeds are each of them included in a ſeparate Cell.

The *Species* are;

1. CONOCARPODENDRON *foliis argenteis ſericeis latiſſimis. Boerh. Ind. alt.* Silver Tree with broad ſoft white Leaves.

2. CONOCARPODENDRON *folio rigido craſſo anguſto, cono laricis parvo. Boerh. Ind. alt.* Silver Tree with a narrow thick ſtiff Leaf, and a ſmall Cone.

3. CONOCARPODENDRON *folio ſubrotundo craſſo rigido valde nervoſo, cono longo variegato, ex rubro & flavo, flore aureo. Boerh. Ind. alt.* Silver Tree with a roundiſh thick ſtiff Leaf full of Nerves, long Cones variegated with Red and Yellow, and a gold-coloured Flower.

4. CONOCARPODENDRON *folio tenui anguſto ſaligno, cono caliculato, corona foliacea ſuccincto. Boerh. Ind. alt.* Silver Tree with a narrow Willow Leaf, and the Cones growing in ſmall Cups, which are ſurrounded with a Crown of Leaves.

Theſe Plants are at preſent very rare in the *European* Gardens; the natural Place of their Growth is in the Country of the *Hottentots*, near the Cape of *Good Hope*, from whence ſeveral of theſe Kinds have been brought to the Gardens in *Holland*; but I have not obſerved more than two Sorts in the *Engliſh* Gardens: for they are with Difficulty propagated, the Cuttings ſeldom taking Root, tho' managed with the greateſt Care, and the Layers are two or three Years before they are rooted enough to take off; ſo that the ſureſt Method to propagate theſe Plants is by Seeds, which are ſeldom brought from the Country of their Growth; and as they do not yet produce Seeds in *Europe*, ſo they will be ſcarce, unleſs a Quantity of their Seeds could be procured from abroad.

The Seeds ſhould be brought over in their Cones; for if they are taken out, they will loſe their growing Quality, before they arrive in *Europe*. When the Seeds are obtained, they ſhould be ſown early in the Spring of the Year, in Pots filled with light freſh Earth, and plunged into a Hot-bed of Tanners-bark, obſerving frequently to water the Earth, otherwiſe the Seeds will dry, and their Covering become ſo hard, as to prevent their Growing. When the Plants are come up about two Inches high, which may be expected in Six Weeks after ſowing, if the Seed be freſh, they ſhould be carefully ſhaken out of the Pots, and ſeparated, putting each into a ſmall halfpenny Pot, filled with light freſh Earth, and then plunged into a moderate Hot-bed of Tanners-bark; then water them pretty well, to ſettle the Earth to their Roots, and in the Heat of the Day cover the Glaſſes of the Hot-bed, to ſcreen the Plants from the Sun, until they have taken new Root, which will not be longer than a Fortnight; after which time they muſt have a large Share of freſh Air admitted to them, by raiſing the Glaſſes with Bricks every Day, when the Weather is warm: you muſt alſo frequently refreſh them with Water in hot Weather, which if duly obſerved, the Plants will have obtained Strength enough by the Beginning of *July* to bear the open Air, to which they muſt then be inured by Degrees; and the Middle of *July* they ſhould be taken out of the Hot-bed, and placed in a warm Situation, where they may be ſcreened from ſtrong Winds; in which Situation they may remain until the End of *September*, when they ſhould be removed into the Green-houſe. For the firſt Year they are ſomewhat tenderer, than they will be when they are grown large; ſo that the firſt Winter they ſhould be placed in the warmeſt Part of the Green-houſe, where they may enjoy the Heat of the Sun, and be ſecured from Cold.

After the firſt Year theſe Plants may be treated as many other exotic Plants which come from the ſame Country, and only require to be protected from great Cold; ſo may be placed in the open Air during the ſummer Months, and in Winter removed into the Green-houſe, and placed where they may enjoy as much free Air as poſſible in mild Weather; for if theſe Plants are kept too warm, or too cloſely confined from the Air, they will make long weak Shoots, and become ſickly. Theſe Plants muſt be new-potted every Spring, when the Earth ſhould be carefully pared off from their Roots, and freſh Earth added to fill the Pots; and as the Plants advance in Size, ſo they ſhould have larger Pots; but they muſt not be put into Pots too large, for nothing is more injurious to moſt Plants than over-potting of them.

Theſe Plants, in the natural Country of their Growth, become large Trees; but in *Europe*, where they are confined in Pots or Tubs, it cannot be expected they ſhould grow ſo large. The largeſt Plant of theſe Kinds I have yet ſeen, was not more than eight Feet high; but as they retain their Leaves throughout the Year, which are of a fine ſilver Colour, ſo they merit a Place in the Green-houſe, for the beautiful Variety they add among other exotic Plants.

CONSOLIDA Major, *vide* Symphytum.

CONSOLIDA Media, *vide* Bugula.

CONSOLIDA MINIMA, *vide* Bellis.

CONSOLIDA Regalis, *vide* Delphinium.

CONVOLVULUS, [of *Convolvendo*, Lat. *rolling round*, or *wrapping* or *winding about*. Bindweed.

The *Characters* are;

It hath, for the moſt part, trailing Stalks; the Leaves grow alternately upon the Branches; And the whole Plant, for the moſt part, abounds with Milky Juice; the Flower conſiſts of one entire Leaf, ſhaped like a Bell, whoſe Mouth or Brim is, for the moſt part, widely ſpread and expanded; the Ovary becomes a roundiſh membraneous Fruit, which is, for the moſt part, wrapp'd up within the Flower cup; and is generally divided into three Cells, each containing one angular Seed.

The *Species* are;

1. CONVOLVULUS *vulgaris major albus. Mor. Hiſt.* The common great white Bind-weed, *vulgarly call'd* Bearbind.

2. CONVOLVULUS *minor arvenſis, flore roſeo. C. B.* Leſſer Field Bindweed, with a Roſe-colour'd Flower, *vulgarly call'd* Gravel-bind.

3. CONVOLVULUS *maritimus noſtras rotundifolius. Mor. Hiſt.* Common Sea Bindweed with round Leaves, or Soldanella Officin.

4. CONVOLVULUS *marinus catharticus, folio rotundo, flore purpureo. Plum. American* purging Sea Bindweed, with a round Leaf, and a purple Flower.

5. CONVOLVULUS *purpureus, folio ſubrotundo. C. B.* Indian *Convolvulus*, with roundiſh Leaves, and purple Flowers.

6. CONVOLVULUS *Indicus, flore albo. H. R. Par. Indian* Bindweed with white Flowers.

7. CONVOLVULUS *Indicus, flore albo-purpuraſcente, ſemine albo. H. R. Monſp. Indian* Bindweed, with whitiſh-purple Flowers, and white Seeds.

8. CONVOLVULUS *Indicus, flore amplo roſeo. Indian* Bindweed, with large Roſe-colour'd Flowers.

9. CONVOLVULUS *cæruleus hederaceus, ſeu trifolius. Park.* Ivy-leav'd *Indian* Bindweed, with fair blue Flowers.

10. CONVOLVULUS *Canarienſis ſempervirens, folio molli incano, flore ex albo purpuraſcente. H. A.* Perennial *Canary* Bindweed, with ſoft hoary Leaves, and whitiſh purple Flowers.

11. CONVOLVULUS *major heptaphyllos, flore ſulphureo odorato ſpecioſiſſimo. Sloan. Cat. Jam.* Great *American* Bindweed, with ſpecious yellow ſweet-ſcented Flowers, *commonly call'd Spaniſh* Arbor-Vine, or *Spaniſh* Woodbind.

12. CONVOLVULUS *Americanus, folio hederæ, flore coccineo minore. American* Bindweed, with Ivy Leaves, and ſmall ſcarlet Flowers. This is the *Quamoclit Americana, folio hederæ, flore coccineo*, of *Commeline*'s rare Plants.

13. CONVOLVULUS *Luſitanicus, flore cyaneo. Broſſ. Portugal* Bindweed, with fine blue Flowers, *vulgarly call'd* Convolvulus Minor.

14. CONVOLVULUS *Luſitanicus, flore & ſemine albo. Boerh. Ind. alt. Portugal* Bindweed, with white Flowers and Seeds, *vugarly call'd* Colvolvulus minor flore albo.

15. CONVOLVULUS *major rectus Creticus argenteus. Mor. Hiſt.* Great upright Bindweed from *Crete*, with Silver-colour'd Leaves.

16. CONVOLVULUS *linariæ folio, aſſurgens. Tourn.* Upright Bindweed, with Toad-flax Leaves.

17. CONVOLVULUS *radice tuberoſa eſculenta, ſpinachiæ folio, flore albo, fundo purpureo, ſemine poſt ſingulos flores ſingulo. Sloan. Cat.* White and yellow *Spaniſh* Potatoes.

18. CONVOLVULUS *radice tuberoſa eſculenta minore purpurea. Sloan. Cat.* Red *Spaniſh* Potatoes.

19. CONVOLVULUS *radice tuberoſa cathartica. Houſt.* The Jalap.

20. CONVOLVULUS *radice tuberoſa maxima, foliis hederaceis incanis, floribus maximis purpureis, ſemine villoſo. Houſt.* Large tuberous rooted Bindweed, with hoary Ivy Leaves, large purple Flowers, and hairy Seeds.

21. CONVOLVULUS *pentaphyllos, folio glabro dentato, viticulis hirſutis. Plum. Cat.* Five-leav'd Bindweed, with ſmooth indented Leaves, and hairy Stalks.

22. CONVOLVULUS *polyanthos niveus, folio ſubrotundo majori. Plum. Cat. American* Bindweed, with many white Flowers, and a larger roundiſh Leaf.

23. CONVOLVULUS *luteus polyanthos. Plum. Cat.* Yellow many-flowered Bindweed.

24. CONVOLVULUS *ampliſſimo folio cordiformi, flore maxim purpuraſcente. Plum. Cat.* Bindweed with a large heart-ſhaped Leaf, and a large purpliſh Flower.

25. CONVOLVULUS *ampliſſimo folio cordiformi, flore alb maximo. Plum. Cat.* Bindweed with a large heart-ſhaped Leaf, and a large white Flower.

26. CONVOLVULUS *coccineus heptaphyllos, radice craſſiſſima. Plum. Cat.* Scarlet Bindweed, with ſeven Leaves, and a thick Root.

27. CONVOLVULUS *pentaphyllos, hirſutus. Plum. Cat.* Hairy five-leaved Bindweed.

28. CONVOLVULUS *polyphyllos, flore & fructu purpureis maximis. Plum. Cat.* Many-leaved Bindweed, with the largeſt purple Flower and Fruit.

29. CONVOLVULUS *minimus villoſus, helianthemi folio. Plum. Cat.* The leaſt hairy Bindwind, with a dwarf Ciſtus Leaf.

30. CONVOLVULUS *pentaphyllos minor, flore purpureo. Sloan. Cat.* Leſſer five-leaved Bindweed, with a purple Flower.

31. CONVOLVULUS *polyanthos, foliis & viticulis purpureis.* Many-flowered Bindweed, with purple Stalks and Leaves.

32. CONVOLVULUS *Americanus, ariſtolochiæ folio glabro, viticulis hirſutis, flore majore purpureo, ſemine lanuginoſo. American* Bindweed, with a ſmooth Birthwort Leaf, hairy Stalks, a large purple Flower, and hairy Seeds.

33. CONVOLVULUS *Americanus, foliis oblongis hirſutis, flore minore purpuraſcente, ſemine minimo. American* Bindweed, with hairy oblong Leaves, a ſmall purpliſh Flower, and the leaſt Seed.

34. CONVOLVULUS *folio hederæ, flore dilute aurantio. Breyn.* Bindweed with an Ivy Leaf, and a pale Orange-coloured Flower.

35. CONVOLVULUS *Syriacus, & Scammonea Syriaca. Mor. Hiſt.* The Scammony.

36. Convolvulus *Indicus alatus maximus, foliis ibiſco nonnihil ſimilibus, anguloſis. Hort. Lugd. Bat.* The Turbith of the Shops.

The firſt of theſe *Species* is a very troubleſome Weed in Gardens, eſpecially under Hedges, or amongſt the Roots of Trees, where, by its creeping Roots, it increaſes very faſt; and the Plant twiſting itſelf about whatever Plants, *&c.* are near it, will ſpread as far above-ground, overbearing whatever Plant it comes near. The only Remedy that I know of to deſtroy this Plant, is by often houghing of it down; which in one Year's Time (if carefully perform'd, and often repeated) will intirely deſtroy it: For the whole Plant abounds with a milky Juice; and whenever the Top is cut off, it is very ſubject to emit ſo great a Quantity of its Juice, as to deſtroy the whole Branch to the Top; which (as the Gardeners expreſs it) is *bleeding to Death.*

The ſecond ſort, of which there are great Varieties of different-colour'd Flowers, is ſtill a worſe Weed than the former; for the Roots of this Kind do inſinuate themſelves into the Gravel many Feet deep, and greatly increaſe under-ground, riſing and ſpreading its Branches over every thing near it. This I know no other Method to deſtroy, than houghing often, or pulling it up by Hand; which will, in Time, weaken and ſubdue it: But this can't be done under three or four Years, if attended with all poſſible Care, (eſpecially in a dry, ſandy, or gravelly Soil:) But in a wet Soil it is ſoon deſtroy'd; for the Roots are very ſubject to rot with too much Moiſture in Winter.

The third Sort is found in Plenty upon the gravelly or ſandy Shores where the ſalt Water overflows in many Parts of *England.* This is a ſtrong Purger, and as ſuch is often us'd in Medicine. This Plant, if ſown in a Garden, will ſeldom laſt above a Year or two.

The fourth Sort is found in great Plenty upon the Sea-ſhores of *America*, and is by the Inhabitants us'd as a Purge. The Seeds of this Plant were brought from the *Bahama Iſlands* by Mr. *Cateſby*, and have been rais'd in ſeveral Gardens in *England*; but it is very tender, and not to be kept through a Winter without a Stove.

The fifth, ſixth, ſeventh, eighth and ninth Sorts are annual, and are propagated in Gardens for the Beauty of their Flowers: Theſe are commonly ſown on a Hot-bed in *March*, and afterwards tranſplanted into Borders in the open Air, where being ſupported by tall Stakes, they will twiſt round them, and ariſe to a great Height, producing great Quantities of fine large Bell-ſhap'd Flowers, and will continue flowering until the Froſt prevent them.

Theſe may all be rais'd in the open Ground, except the ninth, which, if it is not brought forward in the Spring by a Hot-bed, ſeldom produces ripe Seeds; the reſt are very hardy, and may be ſown to cover Seats, Arbours, Paliſado's, *&c.* which they will do in a ſhort Time, and continue very handſome until the Froſt deſtroys them: The ſeveral Varieties, when intermix'd, make a beautiful Appearance, but the ninth Sort is by far the moſt beautiful of them all.

The tenth Sort is an abiding Plant, and requires a Greenhouſe in Winter: This will grow to a conſiderable Height, and muſt be ſupported by ſtrong Stakes: It flowers almoſt every Year with us, but ſeldom produces good Seeds in *England.* This may be propagated by laying down the tender Branches in the Spring, which by Autumn will have ſufficient Roots to be taken off. Theſe muſt be planted in Pots fill'd with freſh light Earth, and ſhelter'd from Froſts in Winter; but muſt have as much free Air as poſſible in mild Weather, and require frequent Waterings.

The eleventh Sort is very common in the hotter Parts of *America*, where it is known by the Name of *Spaniſh Arbor Vine*: It is by the Inhabitants planted to cover Arbours and Seats, for which Purpoſe it is very proper; for in thoſe Countries one of theſe Plants will grow to the Length of ſixty or a hundred Feet, and produce great Quantities of Side-Branches, by which Means, in a very ſhort Time, it will cover a large Seat: This Plant produces in *America* great Quantities of large fragrant yellow Flowers, which are each of them ſucceeded by three large angular Seeds. It is a very tender Plant with us, and can't be preſerv'd but in warm Stoves through the Winter, nor hath it as yet produc'd any Flowers in *England* that I know of: It riſes eaſily from the Seeds, if they are ſown in a Hot-bed, and will grow to a great Length in one Summer; and altho' I have ſometimes preſerv'd it for two Years, and the Plant has ſpread to a great Length, yet I could never perceive any Attempt to flower.

The twelfth Sort is an annual Plant, and muſt be rais'd and manag'd, as was directed for the fifth, ſixth, *&c.* This produces ſmall Scarlet Flowers with a long Tube; which occaſion'd Monſ. *Tournefort* to range it amongſt the *Quamoclits.* This Plant is in great Plenty in *Carolina.*

The thirteenth and fourteenth Sorts are Annual; but theſe do not climb as the others: The Seeds of theſe Plants may be ſown in open Borders in *March*, where they will come up very wild, and may be afterwards tranſplanted to a greater Diſtance, to adorn the Borders of a Pleaſure-Garden. Theſe Plants trail upon the Ground, if they are not ſupported, and do produce their beautiful Flowers thro' moſt of the Summer Months.

The fifteenth Sort is an abiding Plant, which with us doth grow upright to be three or four Feet high; the Branches are ſet very thick, with long narrow Silver-colour'd Leaves, and the Flowers grow upon the Tops of the Branches in an Umbel. Theſe Flowers are ſometimes ſucceeded by angular Seeds like the other Kinds: It may be propagated by planting Cuttings in any of the Summer Months, obſerving to water and ſhade them until they have taken Root; at which Time they muſt be planted in Pots fill'd with freſh ſandy Soil, and muſt be ſhelter'd in Winter from the Froſts, but require open free Air at all Times when the Weather is mild.

The ſixteenth Sort is a perennial Plant, which increaſes greatly by its creeping Roots: This grows erect about eight or ten Inches high, and produces Flowers ſomewhat like thoſe of our leſſer wild Kind, but ſeldom produces good Seeds with us; but the Plant may be abundantly multiplied by parting the Roots: It is very hardy, and loves a light Soil.

The ſeventeenth and eighteenth Sorts are much cultivated in the *Weſt-Indies*, where they are a great Part of the Food of the Inhabitants; and from theſe Roots they make a Drink which they call *Mobby*; which is done by ſtewing the Roots over a gentle Fire till they are ſoft; then they break the Roots, and put them into fair Water, letting them remain therein two or three Hours, in which Time the Water will have drawn out the Spirit of the Root; then they put the Liquor and Roots into a woollen Bag, and ſtrain the Liquor through into a Jar, when in two Hours after it will begin to work; then they cover the Jar, and let it remain until the next Day, when it will be fit to drink. This Liquor they make ſtronger or weaker, by putting a greater or leſs Quantity of Roots into the Water. It is a very ſprightly Drink, but not ſubject to fly into the Head, nor will it keep good longer than four or five Days.

Theſe Plants are propagated with great Eaſe; for every Piece of the Root, which has an Eye or Bud, will grow, and ſend out Branches trailing on the Ground, which emit Roots at every Joint, and form a large Tuber or Potatoe at each, which in thoſe warm Countries will be full grown, and fit for Uſe in three or four Months time; ſo that from one Root planted there will be twenty or thirty fair Roots produced. Some of theſe Roots have been brought from *America* into *Europe*, and are now frequently cultivated in *Spain* and *Portugal*, from both which Places the Roots are annually brought into *England*, and are by ſome Perſons greatly eſteemed; tho' in general they are not ſo well liked as the common Potatoe, being too ſweet and luſcious for moſt Palates.

In *England* theſe Plants are ſometimes cultivated by curious Perſons, after the following Manner: the latter End of *March*, or the Beginning of *April*, they prepare a Heap of hot Dung; then having choſe a warm Spot of light Ground, they dig Holes about eight Feet aſunder, into each of which they put two or three Barrows of the hot Dung, which muſt be laid ſmooth, raiſing it high in the middle; then they cover the Dung with light rich Earth, and upon the Top of each Hill they plant two or three Pieces of ſound Roots, each having an Eye or Bud; then they cover the Hills with Bell or Hand Glaſſes, to preſerve a Heat in that Part of the Hill where the Roots are planted, as alſo to prevent the Rain from rotting the Roots. In about a Fortnight or three Weeks after planting they will begin to ſhoot, when the Glaſſes muſt be raiſed on one Side every Day, to admit freſh Air to the Plants; and they muſt be frequently refreſhed with Water, but it ſhould not be given them in large Quantities, until the Plants are grown pretty ſtrong, leſt thereby you rot the Roots. When the Vines have ſpread ſo far as to reach the Sides of the Glaſſes, the Glaſſes muſt be raiſed with three Bricks, to allow Room for the Vines to ſpread; but the Glaſſes ſhould not be taken quite away from the Plants until *June*, when the Plants will be paſt Danger of Injury from the Cold. As theſe Vines ſpread, ſo the Ground about them ſhould be looſened, that they may more eaſily ſtrike their Roots into it; and in dry Weather the Vines ſhould be watered all over, three or four times a Week; which greatly ſtrengthen the Plants, and cauſe the Roots which are formed at each Joint of the Vines, to grow large and fair, they muſt alſo be conſtantly kept clear from Weeds, which, if ſuffered to grow amongſt the Plants, will over-bear and greatly weaken or deſtroy them. Theſe Roots muſt remain undiſturbed till Autumn, when the firſt Approach of Froſt will pinch the tender Leaves of the Vines, at which Time you muſt immediately take up the Roots; for if the Froſt ſhould reach them, it will intirely deſtroy them. Theſe Roots may be kept in dry Sand in a warm Place for Uſe in the Winter, and a few of the ſoundeſt muſt be preſerved to make a freſh Plantation in the Spring.

The *Jalap*, whoſe Root has been long uſed in Medicine in *Europe*, is a Native of the Province of *Halapa*, about two Days Journey from *La Vera Cruz* in the *Spaniſh Weſt Indies*, from whence the Root is ſent in great Quantities every Year to *Europe*; but it is of late that the Plant has been known to the *Europeans*; for Dr. *Tournefort*, upon the Information of Father *Plumier*, has delivered it as one Species of the *Marvel of Peru*, and conſtituted the Genus under the Title of *Jalapa:* But my late learned Friend Dr. *William Houſtoun*, who was at *La Vera Cruz* two or three times, procured ſome Plants from *Halapa*, by his Intereſt with an ingenious *Spaniard*; which he carried to *Jamaica*, and planted there; by which he was informed truly, that it was one Species of *Convolvulus*, and accordingly gave it the Name I have here mentioned it under.

This and moſt of the other Sorts of *Convolvulus* here mentioned, were found in ſeveral Parts of *America*, by the forementioned Dr. *Houſtoun*, who ſent the Seeds of them into *England*, where they have been cultivated; but as moſt of them are abiding Plants, and require a warm Stove to preſerve them in Winter, ſo few of them have been maintained here: for they ſpread and ramble ſo far, that few Stoves now built are tall enough to contain them, and if they are intermixed with other Plants, they will twiſt themſelves round whatever Plants grow near them, and will ſoon over-bear and deſtroy them, if not timely prevented. The only Stoves yet built, within my Knowledge, proper for theſe Plants, are at the Right Hon. the Lord PETRE's at *Thorndon-Hall* in *Eſſex*; where there are Borders of Earth in the Back-part of the Stoves, and Trellaſſes thirty Feet high, to ſupport theſe and other climbing Plants; at which Place we may hope to ſee theſe and moſt other exotic Plants of large Growth, in greater Perfection than in any other Part of *Europe*; for this noble Patron of Gardening has erected the moſt judicious and magnificent Stoves that were ever contrived; and theſe are ſo curiouſly ſtocked with Plants from the ſeveral Parts of the World, that it is already (tho' but lately executed) one of the moſt curious and magnificent Sights perhaps in the whole World.

All theſe Sorts of *Convolvulus* are propagated by Seeds, which ſhould be ſown in a moderate Hot-bed early in the Spring: thoſe Sorts which have large Seeds, ſhould be ſown very thin, and buried deeper in the Earth, than thoſe which have ſmall Seeds; in about a Fortnight after they are ſown, the Plants will begin to appear above Ground, when the Glaſſes of the Hot-bed ſhould be raiſed every Day, to admit freſh Air to the Plants; otherwiſe they will draw up weak, and twiſt themſelves together, ſo as to render it difficult to ſeparate them. When the Plants are about three Inches high, they ſhould be carefully taken up, and each planted in a ſmall Pot filled with light freſh Earth, and then plunged into a moderate Hot-bed of Tanners-bark, obſerving to ſhade the Glaſſes every Day with Mats, until the Plants have taken new Root: after which Time they ſhould have a large Share of freſh Air, and in warm Weather they muſt be frequently watered. When the Plants have filled the Pots with their Roots, they ſhould be ſhaken out, and planted into larger Pots, filled with freſh Earth, and then placed in the Stove, where they may have room to climb, and their Shoots either twiſted on an Eſpalier made in the Back-part of the Stove for theſe and other rambling Plants, or elſe ſupported with long Stakes; otherwiſe they will ramble over whatever Plants ſtand near them. Some of theſe Sorts will produce Flowers the firſt Seaſon, but others will not flower until the ſecond or third Year, nor will they flower kindly, unleſs they have a large Share of freſh Air, eſpecially in warm Weather. Theſe Plants will continue ſeveral Years, provided they are managed rightly; and will produce Flowers and Seeds every Year, and make a fine Appearance in the Stove, when they are in Flower.

CONYZA; [of Κωνώψ, *Gr.* becauſe the Leaves being hung up, drive away Gnats and Fleas, as *Dioſcorides* ſays: It is alſo call'd *Baccharis*, of *Bacchus*; becauſe it breathes out a vinous Scent.] Flea-bane.

The *Characters* are;

It hath undivided Leaves, which, for the moſt part, are glutinous, and have a ſtrong Scent; the Cup of the Flower is, for the moſt part, ſcaly, and of a cylindrical Form; the Flower is compos'd of many Florets, which are ſucceeded by Seeds which have a downy Subſtance adhering to them.

The *Species* are;

1. CONYZA *major, vulgaris. C. B.* Common Great Flea-bane.

2. CONYZA *minor, flore globoſo. C. B.* Leſſer Flea-bane, with globular Flowers.

3. CONYZA *Americana, lamii folio. Tourn. American* Flea-bane, with Leaves of the Dead Nettle.

4. CONYZA *mas, Theophraſti, major Dioſcoridis. C. B.* The Greater Flea-bane of *Dioſcorides*.

5. CONYZA *Cretica, fruticoſa, folio molli, candidiſſimo & tomentoſo. Flor.* Shrubby Flea-bane from *Crete*, with ſoft downy white Leaves.

6. CONYZA *fruticoſa, ciſti odore, floribus pallide purpureis, ſummitatibus ramulorum inſidentibus, capitulis & ſemine minoribus. Sloan. Cat. Jam.* Shrubby *American* Fleabane, ſmelling like the Rock-roſe, with pale purple Flowers growing on the Top of the Branches, and ſmaller Heads and Seeds.

7. CONYZA *fruticoſa, ciſti odore, floribus pallide purpureis, ſummitatibus ramulorum inſidentibus, capitulis & ſemine majoribus. Sloan. Cat. Jam.* Shrubby *American* Fleabane, ſmelling like the Rock-roſe, with pale purple Flowers growing on the Top of the Branches, and larger Heads and Seeds.

8. CONYZA *arboreſcens tomentoſa, foliis oblongis, floribus in ſummitatibus ramulorum racemoſis ſparſis albicantibus. Houſt.* Woolly Tree-like Flea-bane, with longiſh Leaves, and white Flowers, growing in thin Bunches on the Top of the Branches.

9. CONYZA *fruteſcens, flore luteo umbellato. Houſt.* Shrubby *American* Flea-bane, with yellow Flowers, growing in an Umbel.

10. CONYZA *arboreſcens, foliis oblongis, floribus ſingulis, tribus floſculis conſtantibus. Houſt.* Tree-like *American* Flea-bane, with longiſh Leaves, and each Flower has conſtantly three Florets.

11. CONYZA *ſcandens, lauri foliis aſperis, capitulis ſpicatis rotundis, floribus albis. Houſt.* Climbing *American* Flea-bane, with rough Bay-leaves, and white Flowers growing on round Spikes.

12. CONYZA *fruticoſa, flore pallide purpureo, capitulis e lateribus ramulorum ſpicatim exeuntibus. Sloan. Cat. Jam.* Shrubby *American* Flea-bane, with pale purple Flowers growing in Spikes from the Side and at the Top of the Branches.

13. CONYZA *major odorata, ſive Baccharis, floribus purpureis nudis. Sloan. Cat. Jam.* Greater ſweet-ſmelling Flea-bane, with naked purple Flowers.

14. CONYZA *major inodorata, helenii folio integro, ſicco & duro, cichorii flore albo, e ramorum lateribus exeunte. Sloan. Cat.* Greater unſavory Flea-bane, with hard dry Elecampane Leaves, and white Flowers growing from the Side of the Branches.

15. CONYZA *fruticoſa, folio haſtato, flore pallide purpureo. Sloan. Cat. Jam.* Shrubby *American* Flea-bane, with a ſpear-ſhaped Leaf, and a pale purple Flower.

16. CONYZA *urticæ folio. Sloan. Cat. Jam. American* Flea-bane with a Nettle Leaf.

17. CONYZA *herbacea, caule alato, ſalicis folio, floribus umbellatis purpureis minoribus. Houſt.* Herbaceous *American* Flea-bane, with a Willow Leaf, and ſmaller purple Flowers growing in an Umbel.

18. CONYZA *odorata, bellidis folio villoſo & viſcoſo. Houſt.* Sweet-ſmelling Flea-bane, with a viſcous hairy Daizy Leaf.

19. CONYZA *ſymphyti facie, flore luteo. Houſt. American* Flea-bane, with the Face of Comfery, and a yellow Flower.

20. CONYZA *linariæ folio, floribus parvis ſpicatis albis. Houſt. American* Flea-bane, with a Toad-flax Leaf, and ſmall white Flowers growing in Spikes.

The firſt of theſe Species is found wild upon dry chalky Hills in divers Parts of *England*, and is ſeldom cultivated in Gardens: It is a biennial Plant, being ſown in the Spring: It flowers the ſecond Year, and after producing Seeds it decays.

The ſecond Sort grows on boggy Places, or where the Water has ſtood all the Winter, in many Parts of *England*: It may be propagated in a Garden by ſowing the Seeds ſoon after they are ripe. This Plant is an Annual, and never continues above one Year. This is the Species which is ſometimes uſed in Medicine.

The third Sort is very common in *Barbadoes*, and many other Parts of *America*; it very often comes up in great Plenty in the Earth that is brought from thence. This is an annual Plant, and muſt be ſown in a Hot-bed, and managed as hath been directed for the *Balſamina*, to which I refer the Reader.

The fourth Sort is ſaid to grow in great Plenty about *Montpelier*: This is ſomewhat like the firſt Sort, and may be propagated by ſowing the Seeds ſoon after they are ripe, which will flower the ſucceeding Summer, and after perfecting its Seeds decays.

The fifth Sort is an abiding Plant, which with us ſeldom riſes above eighteen Inches high, but hath woody Branches; the Leaves are very white and ſoft, which renders them very agreeable when intermix'd with different colour'd Plants in large Borders; but the Flowers have no great Beauty in them. This Plant is very hardy, and will endure our ſevereſt Cold in the open Borders, and may be propagated by planting Cuttings in any of the Summer Months.

The ſhrubby Flea-banes are Natives of the *Weſt-Indies*, where they uſually grow about ſix or ſeven Feet high, and ſome of the Tree-kinds ten or twelve Feet high, and divide into many Branches. They are all propagated by Seeds, which ſhould be ſown ſoon after they are ripe; for as they have light downy Seeds, ſo they will nor retain their growing Quality very long. If the Seeds are ſown in Autumn, they will remain in the Ground all the Winter, and the Plants will appear the following Spring; but then the Pots in which the Seeds are ſown, ſhould be plunged into a Hot-bed of Tanners-bark, and ſecured from Cold, otherwiſe the Seeds will periſh in Winter. And when the Seeds are kept out of the Ground till Spring, they ſeldom grow: but as theſe Plants ſeldom produce Seeds in this Country, ſo the ſureſt Method to obtain theſe Plants, is to have their Seeds ſown in a Box of Earth ſoon after they are ripe, in the natural Countries of their Growth, and ſent over to *England*. When theſe Tubs of Earth arrive, they ſhould be plunged into a moderate Hot-bed of Tanners-bark, and frequently refreſhed with Water, which will ſoon bring up the Plants, if their Seeds were not deſtroyed in their Paſſage.

When the Plants begin to appear above Ground, the Glaſſes of the Hot-bed ſhould be raiſed every Day in warm Weather, to admit freſh Air to the Plants; otherwiſe they will draw up weak, and be ſoon ſpoiled: they muſt alſo be frequently refreſhed with Water in warm Weather; for they are all very thirſty Plants, moſt of them naturally growing in low ſwampy Grounds. When the Plants are grown about two Inches high, they ſhould be carefully taken up, and each planted in a ſeparate Pot filled with light freſh Earth, and plunged into a moderate Hot-bed of Tanners-bark, obſerving to ſhade the Glaſſes of the Hot-bed every Day with Mats, to ſcreen the Plants from the Heat of the Sun, until they have taken new Root; after which Time they muſt have a large Share of freſh Air, as alſo a great Quantity of Moiſture in warm Weather. In Winter, theſe Plants muſt be placed in the Stove, where they may enjoy a moderate Warmth; for if they are kept too hot, they will make weak Shoots in Winter, which will render them very unſightly. In Summer theſe Plants muſt have a large Share of freſh Air, but they muſt not be placed in the open Air, for they are too tender to thrive abroad in this Climate.

Theſe Plants will produce their Flowers in two or three Years after they are raiſed, and will continue many Years, provided they are carefully managed, and will flower annually toward the latter Part of the Summer.

The herbaceous Kinds muſt be propagated in the ſame manner as hath been directed for the woody Kinds; but theſe will decay annually to the Surface, and riſe again every Spring from the Root. When the green Shoots begin to decay, the Plants ſhould not be over watered, leſt thereby the Roots ſhould be rotted; but during the Time of their Growth, they muſt be plentifully watered. The ſureſt Method to have theſe Plants produce their Flowers, is, to plunge the Pots into a moderate Hot-bed of Tanners-bark, in the Spring, always obſerving to let them have a large Share of Air in warm Weather, to prevent their ſhooting too weak, and water them frequently; with this Management they will produce their Flowers every Year: but as they rarely produce ripe Seeds in *England*, ſo the Pots muſt be removed into the Stove in Winter to preſerve their Roots, which may be parted in the Spring, at the Time when they are plunged into the Hot-bed, by which Method they may be increaſed.

CONSERVATORY. *Vide* Green-houſe.

CONVAL-LILY. *Vide* Lilium Convallium.

COPAIBA, The Balſam of Capevi Tree.

The *Characters* are;

It hath a Flower conſiſting of five Leaves, which expands in Form of a Roſe; the Pointal is fixed in the Center of the Flower, which afterward becomes a Pod; in which are contained one or two Seeds, which are ſurrounded with a Pulp of a yellow Colour.

We know but one Sort of this Tree, which is;

Copaiba *folio ſubrotundo, flore rubro.* The Balſam of Capevi, with a roundiſh Leaf, and a red Flower.

This Tree grows near a Village called *Ayapel*, in the Province of *Antiochi*, in the *Spaniſh Weſt-Indies*, this is about ten Days Journey from *Carthagena*. There are great Numbers of theſe Trees in the Woods about this Village, which grow to the Height of fifty or ſixty Feet; ſome of theſe Trees do not yield any of the Balſam; thoſe which do, are diſtinguiſhed by a Ridge which runs along their Trunks; theſe Trees are wounded in their Center, and they place Calabaſh Shells, or ſome other Veſſels to the wounded Part, to receive the Balſam, which will all flow out in a ſhort Time. One of theſe Trees will yield five or ſix Gallons of the Balſam; but tho' theſe Trees will thrive well after being tapp'd, yet they never afford any more Balſam.

As this Balſam is uſed in Medicine, ſo it deſerves our Application to procure the Trees, and cultivate them in ſome of the *Engliſh* Colonies of *America*; for as the *Engliſh* are poſſeſſed of Lands, in ſo many different Latitudes, they might cultivate moſt Kinds of Trees and Plants, from the different Parts of the World, which are uſeful in Medicine, Dying, or for any other Purpoſe of Life.

The Seeds of this Tree were brought from the Country of their Growth, by Mr. *Robert Millar*, Surgeon, who ſowed a Part of them in *Jamaica*, which he informed me, had ſucceeded very well; ſo that we may hope to have theſe Trees propagated in great Plenty in a few Years, in ſome of the *Engliſh* Colonies, if the Slothfulneſs of the Inhabitants doth not ſuffer them to periſh, as they have the *Cinnamon-tree*, and ſome other uſeful Plants, which have been carried thither by curious Perſons.

There are not at preſent any of theſe Trees in *Europe*, that I can learn; for thoſe Seeds which Mr. *Millar* ſent over to *England*, were all deſtroyed by Inſects in their Paſſage, ſo that not one of them ſucceeded in the ſeveral Places where they were ſown: But could freſh Seeds be procured, the Plants might be raiſed in *England*, and preſerved in the Bark-Stoves very well; for the Country of their Growth is much more temperate than many others, from whence we have been furniſhed with a great Variety of Plants, which ſucceed very well in the Stoves, and ſome of them arrive to a great Degree of Perfection.

CORALLODENDRON; [of Κοράλιον, *Coral*; and δένδρον, *Gr.* a *Tree.*] The Coral-Tree.

The *Characters* are;

It hath the Appearance of a Tree; the Leaves, for the moſt part, conſiſt of three Lobes; the Flowers are papilionaceous; the Standard (or Vexillium) is long, and ſhaped like a Sword; The Wings on each Side, and the Keel (or Carina) are very ſhort; the Flowers are ſucceeded by knobbed bivalve Pods, which contain ſeveral Kidney-ſhap'd Seeds.

The *Species* are;

1. Corallodendron *triphyllon, Americanum, ſpinoſum, flore ruberrimo. Tourn.* The three-leav'd *American* Coral-tree, with deep red Flowers, *commonly called* in *America* the Bean-tree.

2. Corallodendron *Americanum, non ſpinoſum, foliis magis acuminatis flore longiore:* An, *Coral arbor non ſpinoſa, flore longiore & magis clauſo. Sloan. Cat. Jam. American* Coral-tree without Spines, having ſharp-pointed Leaves and long Flowers.

3. Corallodendron *Carolinianum, floribus ſpicatis coccineis radice craſſiſſima.* Thick-rooted *Carolina* Coral-tree, with Scarlet Flowers growing in Spikes.

4. Corallodendron *triphyllum Americanum minus, ſpinis & ſeminibus nigricantibus. Tourn.* Leſſer three-leav'd *American* Coral-tree, with blacker Seeds and Spines.

5. Corallodendron *triphyllum Americanum non ſpinoſum, foliis acutioribus, flore pallido rubente.* Three-leav'd *American* Coral-tree without Spines, having pointed Leaves, and pale red Flowers.

6. Corallodendron *triphyllum Americanum, caudice & nervis foliorum ſpinoſis armatibus.* Three-leav'd *American* Coral-

tree, whoſe Stalk and the Nerves of the Leaves are armed with Spines.

The firſt and ſecond Species do grow with us to be eight or ten Feet high, with ſtrong woody Stems, and produce very beautiful ſcarlet Flowers, but never produce any Seeds in the *European* Gardens, as I can hear of. They may be rais'd by ſowing their Seeds, which are brought from *America*, in a Hot-bed in the Spring of the Year, which will very eaſily come up: The young Plants ſhould, when they are five or ſix Inches high, be carefully tranſplanted into Pots of light freſh Earth, and plung'd into a Hot-bed, obſerving to ſhade them from the Heat of the Sun, until they have taken freſh Root; after which they ſhould have Air given them, by raiſing up the Glaſſes in the Day-time when the Weather is warm; and in *July* and *Auguſt*, they ſhould have a greater Share of Air, in order to harden them before Winter; and in *September*, they ſhould be remov'd into the Stove, and during the Winter-ſeaſon ſhould have but little Water given them, for they commonly caſt their Leaves in Winter, and puſh them out freſh the ſucceeding Spring.

Theſe Plants may alſo be propagated by planting Cuttings in any of the Summer Months, which ſhould be put into Pots filled with freſh light Earth, and plung'd into a moderate Hot-bed of Tanner's Bark, obſerving to ſhade the Glaſſes in the Heat of the Day, and to give them gentle Refreſhings with Water, as the Earth in the Pots is found to dry. In two Months Time theſe Cuttings will have ſufficient Roots to tranſplant; at which Time they muſt be put each into a ſingle Pot, and plung'd again into the Hot-bed, and manag'd as was directed for the Seedling Plants.

In four or five Years Time theſe Plants will produce Flowers, if they are preſerv'd in a moderate Warmth all the Winter; for if they are kept too warm, they are ſubject to grow all the Winter, and the Shoots will be thereby drawn too weak to produce Flowers; and if they are kept too cold, they are liable to loſe their tender Buds which ſhould produce the Flowers: Therefore if they are kept up to the temperate Point mark'd on Mr. *Fowler*'s Thermometer during the Winter Seaſon, they will ſucceed very well.

The third Sort was rais'd from Seeds which were ſent from *Carolina* by Mr. *Cateſby*, *Anno* 1724. This Plant ſeldom riſes above three Feet high with us, and hath large knobbed Roots; the Flowers are produc'd in Spikes upon the Branches, in the Summer Seaſon, when the Plant is almoſt deſtitute of Leaves, but never produces ripe Seeds with us.

This Plant is ſomewhat hardier than the other two Species, and may be kept in a leſſer Degree of Heat in Winter, and be expos'd to the open Air during the Months of *June*, *July*, and *Auguſt*. I have not been able yet to propagate this Plant by Cuttings, but there is no Doubt of its ſucceeding as well as the other two Sorts.

The Seeds of the laſt three Sorts were ſent from *Carthagena* in *New Spain*, by Mr. *Robert Millar*, who collected them in the Neighbourhood of that Place. Theſe are propagated in the ſame Manner as the firſt three Sorts.

CORCHORUS, Jews Mallow.

The *Characters* are;

The Leaves are produced alternately at the Joints of the Stalks; the Cup of the Flower conſiſts of five Leaves; the Flower hath five Leaves, which expand in Form of a Roſe; *the Pointal of the Flower becomes a cylindrical Fruit, which is divided into five Cells which are fill'd with angular Seeds.*

The *Species* are;

1. CORCHORUS *ſive Melochia. J. B.* Common Jews Mallow.
2. CORCHORUS *Americana, Carpini foliis, ſextuplici capſula prælonga. Pluk. American* Jews Mallow, with Leaves like the *Hornbeam*, with long Pods.
3. CORCHORUS *Americana, prælongis foliis, capſula ſtriata ſubrotunda brevi. Pluk. American* Jews Mallow, with long Leaves and ſhort roundiſh furrow'd Pods.
4. CORCHORUS *Orientalis, brevioribus foliis, flore flavo, fructu caryophilloide longiori. Pluk.* Eaſtern Jews Mallow, with ſhort Leaves and long Pods ſhap'd like a Clove.

The firſt Species, *Rauwolf* ſays,* is ſown in great Plenty about *Aleppo* as a Pot-herb; the *Jews* boiling the Leaves of this Plant to eat with their Meat: This he ſuppoſes to be the *Olus Judaicum* of *Avicenna*, and the *Corchorum* of *Pliny*.

The Varieties of this Plant are preſerv'd in curious Botanick Gardens to add to their Number of Plants, but it being of no great Beauty or Uſe with us, is ſeldom propagated in other Gardens.

They are all of them Annual, and muſt be ſown on a Hot-bed early in the Spring, and afterward treated as the Female *Balſamine*; to which I ſhall refer the Reader for their Culture. They delight in a rich Soil, and muſt have frequent Waterings in dry Weather.

Their Flowers are produced in *June* and *July*, and their Seeds ripen in *September*.

CORIANDRUM; [Κοριάννον, of Κόρις, *Gr.* a *Tick*; ſo called, either becauſe it has the Scent of this Inſect, or, as others ſay, becauſe it drives away or kills them; and Ἀνδρὸς, Gr. the *Iſle* where it grew plentifully.] Coriander.

The *Characters* are;

It hath a fibroſe annual Root; the lower Leaves are broad, but the upper Leaves are deeply cut into fine Segments; the Petals of the Flower are unequal, and ſhap'd like a Heart; the Fruit is compos'd of two hemiſpherical (and ſometimes ſpherical) Seeds.

The *Species* are;

1. CORIANDRUM *majus. C. B.* Greater Coriander.
2. CORIANDRUM *minus, teſticulatum. C. B.* Smaller teſticulated Coriander.
3. CORIANDRUM *ſylveſtre, fœtidiſſimum. C. B.*

The firſt of theſe Species is the moſt common Kind, which is cultivated in the *European* Gardens and Fields for the Seeds, which are us'd in Medicine. The ſecond Sort is leſs common than the firſt, and is ſeldom found but in Botanick Gardens in theſe Parts of *Europe*. The third Sort, as mention'd in *Caſpar Bauhin*'s *Pinax*, and cited by the learned *Boerhaave*, in his Catalogue of the *Leyden* Garden, is ſo like the firſt, that I could find no Difference between them when compar'd together, tho' I receiv'd the Seeds of this Kind from the *Leyden* Garden.

Theſe Plants are propagated by ſowing their Seeds early in the Spring, in an open Situation in a Bed of good freſh Earth; and when the Plants are come up, they ſhould be houghed out to about four Inches Diſtance every Way clearing them from Weeds; by which Management theſe Plants will grow ſtrong, and produce a greater Quantity of good Seeds.

CORIARIA, Myrtle-leav'd Sumack, *vulgo*.

The *Characters* are;

It hath a Flower compoſed of ten Stamina (or Threads) each having two Apices, and ariſe from the Bottom of the Calyx, which is divided into five Parts to the Baſe. When the Flower is paſſed, the Pointal (which is contained in another Cup, divided alſo into five Parts to the Baſe) becomes (jointly with the Cup) a Fruit containing five Kidney-ſhap'd Seeds.

We have but one *Species* of this Plant, which is;

CORIARIA *vulgaris. Mem. Acad. Scien. Ann.* 1711. Myrtle-leav'd Sumack, *vulgo*.

This is a low Shrub, ſeldom riſing above three or four Feet high; the Flowers appear in *April*, which are produced from the Joints all the whole Length of the Shoots. Theſe conſiſt of ſeveral Stamina, or Threads, which are of a red Colour; but there is no great Beauty in the Plant.

I have obſerved, that the ſeveral Plants we have in the *Engliſh* Gardens, have no Embryo or Rudiment of the Fruit; which makes me ſuſpect, that they are Male and Female in different Plants; but as Monſieur *Niſſol*, a curious Botaniſt of *Montpelier*, who has given a particular Account of this Plant to the Academy of Sciences at *Paris*, has taken no Notice of this Difference; I muſt leave it to be decided by thoſe who may have an Opportunity of examining the Plants in the Country of their Growth.

It may be propagated plentifully from the Suckers, which are produced from the creeping Roots in great Abundance: Theſe ſhould be taken off in *March*, and planted into a Nurſery, to form good Roots; where they may continue one or two Years, and then muſt be removed to the Places where they are to remain.

This Plant delights in loamy Soil, which is not too ſtiff; and ſhould be placed where it may have Shelter from the North and Eaſt Winds, where it will endure the Cold of our ordinary Winters very well, and will flower better than if it is preſerved in Pots, and ſheltered in the Winter, as is by ſome practiſed.

This Plant is uſed by the Tanners for dreſſing their Leather in the South Parts of *France*, where it grows wild in great Plenty.

CORINDUM; [of *Cor* the Heart, becauſe this Seed has a bright Spot reſembling a Heart; and *Indum*, becauſe it is brought from *India*. This Plant is ſaid to be a very high *Cardiac*. It is alſo call'd *Halicacabus*, of κάκαβος, a *Veſſel*, becauſe the Fruit of this Plant reſembles a Kettle.] Heart-Peas.

The *Characters* are;

It hath a trailing Stalk, emitting Claſpers whereby it faſtens itſelf to whatever Plant it ſtands near: The Calyx (or Flower-cup) conſiſts of three Leaves; the Flowers conſiſt of eight Leaves, and are of an anomalous Figure; the Ovary becomes a Fruit which is like a Bladder, and divided into three Cells, in which are contain'd round Seeds in Form of Peas, of a black Colour, having the Figure of a Heart of a white Colour upon each.

The *Species* are;

1. Corindum *folio ampliori, fructu majore. Tourn.* Heart-Pea, with large Leaves and Fruit.
2. Corindum *folio & fructu minore. Tourn.* Heart-pea, with ſmall Leaves and Fruit, *called by the Inhabitants of the* Weſt Indies, Wild Parſley.
3. Corindum *folio ampliſſimo, fructu minore.* Heart-pea, with very large Leaves, and ſmall Fruit.

Theſe Plants are very common in *Jamaica*, *Barbadoes*, and moſt of the other warm Iſlands in the *Weſt Indies*, where their Seeds are ſcatter'd and become Weeds all over the Country.

They may be cultivated in *England*, by ſowing their Seeds on a Hot-bed in *March*; and when the Plants come up, they muſt be tranſplanted into a freſh Hot-bed, where they may remain until the Middle of *May*; at which Time they may be tranſplanted into Pots or Borders, and expos'd to the open Air. Theſe Plants will require Sticks to ſupport them; otherwiſe their Branches will trail upon the Ground, and be apt to rot, (eſpecially in a wet Seaſon). There is no great Beauty in this Plant; it is chiefly preſerved as a Rarity in the Gardens of the Curious. It produces its Flowers in *June*, and the Seed are perfected in *Auguſt*.

CORIS. We have no *Engliſh* Name for this Plant.

The *Characters* are;

It hath a monopetalous perſonated Flower, whoſe hinder Part is tubulous, but the fore Part is ſhaped like a Fan; from the Flower-cup riſes the Pointal, fixed like a Nail in the hinder Part of the Flower, which afterward becomes a globular Fruit, divided into ſeveral Parts, containing roundiſh Seeds, which are incloſed by the Calyx.

The *Species* are;

1. Coris *cœrulea maritima. C. B. P.* Maritime blue Coris.
2. Coris *maritima, flore rubro. C. B. P.* Maritime Coris with a red Flower.
3. Coris *maritima, flore albo. H. R. Monſp.* Maritime Coris with a white Flower.

Theſe Plants grow wild about *Montpelier*, and in moſt Places in the South of *France*; they ſeldom grow above a Foot high, and ſpread near the Surface of the Ground like Heath; and in *June*, when they are full of Flowers, they make a very pretty Appearance.

They may be propagated by ſowing of their Seeds in the Spring, on a Bed of freſh Earth; and when the Plants are about three Inches high, they ſhould be tranſplanted, ſome of them into Pots filled with freſh light Earth, that they may be ſheltered in Winter, and the others into a warm Border, where they will endure the Cold of our ordinary Winters very well, but in ſevere Froſt they are generally deſtroyed; for which Reaſon, it will be proper to have ſome Plants of each Sort in Pots, which may be put under a common Hot-bed Frame in Winter, where they may be covered in froſty Weather; but when it is mild, they ſhould have a great Share of free Air. Theſe Plants ſometimes produce ripe Seeds in *England*; but as they do not conſtantly perfect their Seeds, ſo it will be proper to increaſe them from Slips and Cuttings, which will take Root if planted in *April*, on a very gentle Hot-bed, and ſhaded from the Sun, and duly watered.

CORK-TREE. *Vide* Suber.

CORN-FLAG. *Vide* Gladiolus.

CORNICULATE PLANTS, [*Plantæ Corniculatæ*, or ſuch as after each Flower produce many diſtant horned Seed-pods, call'd *Siliquæ*.

CORN-MARYGOLD. *Vide* Chryſanthemum.

CORN-SALAD. *Vide* Valerianella.

CORNUS, [is ſo call'd, of *Cornu*, Lat. a *Horn*; becauſe its Wood, or the Office of its Fruit, is hard as a Horn.] The Cornelian Cherry.

The *Characters* are;

The Calyx (or Flower-cup) conſiſts of four ſmall rigid Leaves, which are expanded in Form of a Croſs; from the Center of which are produced many ſmall yellowiſh Flowers, each conſiſting of four Leaves, which are diſpoſed almoſt in Form of an Umbrella. Theſe Flowers are ſucceeded by Fruit, which are oblong, or of a cylindrical Form, ſomewhat like an Olive, containing a hard Stone, which is divided into two Cells, each containing a ſingle Seed.

The *Species* are;

1. Cornus *hortenſis, mas. C. B.* The Cornelian-Cherry, or Male Cornel-tree.
2. Cornus *fœmina. C. B.* The Dog-berry, or Gatten-tree.
3. Cornus *fœmina, foliis variegatis. H. L.* The ſtrip'd Dog-berry-tree.
4. Cornus *fœmina, Laurifolia, fructu nigro cœruleo, oſſiculo compreſſo, Virginiana. Pluk. Alm.* The *Virginian* Dog-berry-tree.
5. Cornus *mas, odorata, folio trifido, margine plano, Saſſafras dicta. Pluk. Alm.* The Saſſafras-tree.
6. Cornus *fœmina Virginiana, anguſtiore folio.* The *Virginian* Dog-berry-tree, with a narrower Leaf.
7. Cornus *mas Virginiana, foliis oblongis, fructu rubro majore.* The Male *Virginian* Dog-berry, with oblong Leaves, and a larger red Fruit.
8. Cornus *mas Virginiana, floſculis plurimis albidis, ex involucro tetrapetalo rubro irrumpentibus. D. Baniſter. Pluk. Phyl. Tab. 26. F. 3. Virginia* Dog-berry, with many ſmall white Flowers, coming out of a four-leav'd red Involucrum.
9. Cornus *racemoſa, trifolia & quinquefolia, foliis foraminulatis. Plum. Cat.* Branching *American* Dog-berry, with three or five Leaves.
10. Cornus *pumila, herbacea, Chamœpericlymenum dicta. Hort. Elth.* Dwarf Honeyſuckle, *vulgo*.

The firſt of theſe Trees is very common in the *Engliſh* Gardens, being propagated for its Fruit; which is by many People preſerv'd, to make Tarts: It is alſo uſed in Medicine as an Aſtringent and Cooler. There is alſo an Officinal Preparation of this Fruit, call'd *Rob de Cornis*.

The ſecond Sort is very common in the Hedges in divers Parts of *England*, and is ſeldom preſerv'd in Gardens. The Fruit of this Plant is often brought into the Markets, and ſold for *Buckthorn Berries*; from which it may be eaſily diſtinguiſhed, if the Berries are opened to obſerve how many Stones there are in each, which in this Fruit is but one, but in the *Buckthorn* four.

The third is alſo a Variety of the ſecond, and is preſerv'd for its variegated Leaves, in ſeveral curious Gardens.

The fourth Sort is at preſent pretty rare in *England*: It is brought from *Virginia* and *Carolina*, where it grows in great Plenty.

The fifth Sort is alſo a Native of *America*, and is rarely found in the *European* Gardens. The Root of this Tree is much uſed in *England*, to make a Tea which is greatly commended by ſome againſt violent Defluxions.

The firſt, ſecond, and third Species are propagated by laying down their tender Branches, which in one Year's Time will take ſufficient Root to be tranſplanted; at which Time they may be either planted in a Nurſery, or in the Places where they are to remain. During the two firſt Years, Care ſhould be taken to train their Stems upright; otherwiſe they are very ſubject to ſhoot crooked, and appear unſightly: But when they are grown up to a regular Size, they ſhould not be pruned, eſpecially if you would have Plenty of Fruit.

Theſe Trees commonly riſe with us to be eight or ten Feet high, or more, and are proper to intermix with Trees of the ſame Growth in ſmaller Quarters of Trees and Shrubs, where they will add to the Variety; and if they are not too much crowded with other Trees, will produce large Quantities of Fruit.

The fourth Sort may be alſo propagated by *Layers*; but muſt have a good Soil, and a Situation which is well defended from the North and Eaſt Winds, and loves to grow in the Shelter of other Trees. This may be alſo rais'd from Seeds, which ſhould be ſown ſoon after they are ripe, and ſhelter'd from ſevere Froſts under a Frame: The ſecond Spring after ſowing, the Plants will come up, which muſt alſo be ſcreen'd from ſevere Froſts while young, but afterwards they will endure our hardeſt Winters abroad.

The beſt Seaſon for tranſplanting theſe Trees, is toward the latter End of *March*, or the Beginning of *April*, juſt before they begin to ſhoot; obſerving to ſhade and water them (if the Weather ſhould prove hot and dry) for about a Fortnight after removing; as alſo to cover the Surface of the Ground with a little Mulch, to preſerve the Earth from drying too faſt: And if the Summer ſhould prove very dry, it would be convenient to give them a little Water once a Week; and after they are well rooted in the Ground, they will want little farther Care.

The *Saſſafras* is one of the moſt difficult Trees to grow with us, that I know; it will rarely live, if kept in Pots and preſerv'd in a Green-houſe; nor will it endure our open Air abroad; The beſt Culture that I can preſcribe, is to remove it carefully in *April* into a good ſtrong Soil, and in a Situation that is well defended by other Trees, both from the cold Winds and open Sun: but they muſt not ſtand under the Dropping of other Trees. In the Winter it will be proper to lay a little Mulch upon the Surface of the Ground round their Stems, to prevent the Froſt from penetrating too deep into the Ground: but their Heads ſhould by no means be cover'd; which, tho' practiſ'd by ſome, yet I am ſure doth more harm than good: In the Summer Seaſon they muſt be kept clear from Weeds, &c. In this Management, I have ſeen the moſt promiſing Trees of this Kind.

Theſe Trees are generally brought over from *Virginia* or *Carolina* to curious Perſons, in both which Places they abound very much, and do propagate themſelves by their creeping Roots; as alſo their Berries, which fall to the Ground, and come up in great Plenty: But with us they are not ſo eaſily increas'd; it being with great Difficulty procur'd by *Layers*, which are commonly two Years before they are furniſh'd with Roots enough to tranſplant, and is alſo with as much Difficulty remov'd. And the Berries which are brought from *America* ſeldom ſucceed with us: They are always two Years before they come up, and then make but a very ſmall Advance for two or three Years after, and it is very rare that many of them are preſerv'd ſo as to ſucceed.

The beſt Method of ſowing the Seeds, is to put them into a Bed of freſh good Earth ſoon after the Seeds are ripe, in a Situation where they may have the Morning Sun until Eleven o' Clock; and in hard froſty Weather cover the Surface of the Ground with Litter: in ſuch a Bed you may expect (if the Seeds were freſh) the Plants to come up the ſecond Spring, which ſhould alſo be cover'd with light Litter or Peas-haulm the firſt Winter, until they have Strength to reſiſt the ſevere Cold of our Climate; after which Time, they muſt be treated as was before directed; theſe Plants delight in a moiſt Soil.

The ſixth, ſeventh, and eighth Sorts are very hardy Plants, ſo will thrive very well in the open Air in this Climate; they may be propagated either by Seeds or Layers; but as their Seeds are ſeldom perfected in this Country, ſo the laying down of their tender Branches in the Spring, is the moſt expeditious Method of propagating them; for when the Seeds are procured from abroad, they remain a whole Year in the Ground, before the Plants appear; whereas the Layers will be ſufficiently rooted in one Year for tranſplanting, ſo that they will have two Years Growth Advance of thoſe raiſed from Seeds.

Theſe Plants thrive beſt on a moiſt light Ground; for in the Country of their natural Growth, they are commonly found in ſwampy Places. They uſually grow about ten or twelve Feet high, and ſpread pretty much on every Side into Branches; ſo ſhould be intermixed with Shrubs of the ſame Growth, in Wilderneſs Quarters, where they will make an agreeable Variety.

The ninth Sort is much more tender than either of the former; theſe may be propagated by Seeds, which muſt be ſown in Pots filled with light freſh Earth, and plunged into a moderate Hot-bed of Tanners-bark, obſerving to water the Pots frequently in warm Weather, as alſo to raiſe the Glaſſes of the Hot-bed to admit freſh Air. Theſe Seeds many Times remain in the Ground a whole Year before the Plants will appear; in which Caſe you muſt let the Pots remain in the Hot-bed, being careful to weed them; and in Winter the Glaſſes muſt be covered with Mats to prevent the Froſt from getting to the Seeds, which will deſtroy them. When the Plants come up, they muſt be frequently watered; and when they are about three Inches high, they ſhould be taken carefully out of the Pots, and each planted in a ſeparate Pot filled with light freſh Earth, and plunged into a moderate Hot-bed, obſerving to ſcreen them from the Sun until they have taken new Root; after which Time they muſt be frequently watered, and in warm Weather ſhould have a large Share of freſh Air. In Winter they muſt be placed in the Stove; for while theſe Plants are young, they are tender; but when they have acquir'd Strength, they may be placed in the Green-houſe in Winter, and in Summer they may be expoſed in the open Air in a warm Situation. Theſe Plants will produce their Flowers in *England*, but they never perfect their Seeds in this Country.

The Dwarf Honey-ſuckle grows on *Cheviot Hills* in *Northumberland*, and on many high Mountains in *Northern* Countries, but are with Difficulty preſerved in Gardens. They muſt be planted in a ſtrong moiſt Soil, and a ſhady Situation; where they will ſometimes produce Flowers, but ſeldom abide many Years in Gardens.

CORNUTIA. (We have no *Engliſh* Name for this Plant. *It is ſo called from* CORNUTUS, *a Phyſician of* Paris, *who publiſhed a Hiſtory of* Canada *Plants.*)

The *Characters* are;

It hath a monopetalous, perſonated Flower, whoſe upper Lip ſtands erect, but the under Lip is divided into three Parts; from the Flower-cup ariſes the Pointal, which is fixed like a Nail in the hinder Part of the Flower, which afterward becomes a ſpherical ſucculent Berry, including Seeds which are for the moſt part Kidney-ſhaped.

There is but one *Species* of this Plant yet known, which is;

CORNUTIA *flore pyramidato cæruleo, foliis incanis. Plum.* Cornutia with a pyramidal Flower, and hoary Leaves.

This Plant was firſt diſcovered by Father *Plumier* in *America*, who gave it the Name. It is found in plenty in ſeveral of the Iſlands in the *Weſt Indies*, and at *Campechy* and *La Vera Cruz*, from both which Places I received the Seeds, which were collected by my late ingenious Friend Doctor *William Houſtoun*.

It is propagated by Seeds, which ſhould be ſown early in the Spring on a Hot-bed; and when the Plants are come up, they ſhould be tranſplanted each into a ſeparate Half-penny Pot, filled with light freſh Earth, and plunged into a Hot-bed of Tanners-bark, obſerving to ſhade them until they have taken Root; after which time they ſhould have freſh Air let into the Bed, in Proportion to the Warmth of the Seaſon, and they muſt be frequently watered (for it naturally grows on ſwampy Soils). When the Plants have filled theſe Pots with their Roots, they ſhould be ſhifted into others of a larger Size, and plunged into the Hot-bed again, where they ſhould be continued till *October*, when they muſt be removed into the Bark-ſtove, and plunged into the Tan; for otherwiſe it will be very difficult to preſerve it thro' the Winter. The Stove in which theſe Plants are placed, ſhould be kept to the temperate Heat marked on Mr. *Fowler's Thermometers*, which will agree better with them than a hotter Stove. The third Year from Seed theſe Plants will flower, when they make a fine Appearance in the Stove, but they never perfect their Seeds in *England*.

They may be alſo propagated by Cuttings, which if planted into Pots filled with freſh Earth, and plunged into a Bark-bed, obſerving to ſhade and water them, will take Root, and muſt be afterwards treated as the Seedling Plants.

CORONA IMPERIALIS; [ſo call'd, becauſe it bears Flowers crown'd with Leaves.] Crown Imperial.

The *Characters* are;

The Flowers conſiſt of ſix Leaves, are Bell-ſhap'd, and hang downwards; theſe are rang'd, as it were, into a Crown; above which appears a great Buſh of Leaves; the Pointal of the Flower becomes an oblong Fruit, which is wing'd, and divided into three Cells, which are fill'd with flat Seeds; to which may be added, it hath a coated Root, which is furniſh'd with Fibres at the Bottom.

The *Species* are;

1. CORONA IMPERIALIS. *Dod.* The common Crown Imperial.
2. CORONA IMPERIALIS *major. Tourn.* The greater Crown Imperial.
3. CORONA IMPERIALIS *flore pleno. Tourn.* Crown Imperial, with a double Flower.
4. CORONA IMPERIALIS *duplici corona. Tourn.* Crown Imperial with a double Crown.
5. CORONA IMPERIALIS *triplici corona. H. L.* Crown Imperial, with a triple Crown.
6. CORONA IMPERIALIS *multiflora latoque caule. Tourn.* Crown Imperial, with many Flowers, and flat Stalks.

7. CORONA IMPERIALIS *folio vario. Tourn.* Strip'd-leav'd Crown Imperial.

8. CORONA IMPERIALIS *folio vario ex viridi & argenteo. Boerh. Ind.* Silver ſtrip'd-leav'd Crown Imperial.

9. CORONA IMPERIALIS *flore pulchre luteo. Tourn.* Crown Imperial, with a beautiful yellow Flower.

10. CORONA IMPERIALIS *flore luteo pleno. Boerh. Ind.* Crown Imperial with a double yellow Flower.

11. CORONA IMPERIALIS *flore luteo ſtriato. Tourn.* Crown Imperial, with a yellow-ſtrip'd Flower.

12. CORONA IMPERIALIS *ramoſa. Tourn.* Branch'd Crown Imperial.

There are ſome other Varieties of this Flower, which are preſerv'd in the Gardens of curious Floriſts: but as they are only Variations which are accidental, from Seeds of the ſame Plant, ſo their Numbers may be increas'd, like many other bulbous Plants, by ſuch who are curious in ſaving and ſowing Seeds of the different Varieties.

The Manner of propagating this Plant from Seeds, being the ſame with the *Tulip*, I ſhall refer the Reader to that Article for the particular Directions, and ſhall proceed to the Method of cultivating their Roots already obtain'd, ſo as to have fair large Flowers.

The beſt Seaſon for tranſplanting their Roots is in *July* or *Auguſt*, before they puſh forth freſh Fibres; after which Time, it is not ſo ſafe to remove them: or they may be taken up in *June*, when their green Leaves are quite decay'd; and may be kept out of the Ground until *Auguſt*, at which Time they ſhould be planted in Beds or Borders of good freſh Earth, burying a little rotten Dung in the Bottom, ſo that the Fibres may ſtrike into it: But be ſure not to let it be near the Bulb, for it is apt to rot whenever this happens.

If they are planted in open Beds or Borders of a Pleaſure-Garden, they ſhould be plac'd exactly in the Middle, for they will riſe to be three Feet high or more in a good Soil, and ſo would be improper to ſtand on the Side of a Border where ſhould be planted Flowers of lower Growth.

In planting of theſe Roots, after the Border is mark'd out, and the Diſtances fix'd between each Root, (which ſhould be eight or ten Feet or more, according to the Size of the Garden, and the Number of Roots to be planted) you ſhould open a Hole with a ſmall Spade about ſix Inches deep, into which you ſhould place your Root, obſerving to ſet the Crown uppermoſt; and then with your Hand fill in the Earth round the Root, breaking the Clods, and removing all large Stones from about it, and afterwards level the Ground with your Spade, and rake the Border over, after all the Roots are planted. Your Roots being thus planted will require no farther Care, as being very hardy; the Froſt never injures them, but if the Ground is too wet in Winter, they will be apt to rot; therefore in ſuch Caſes, the Borders ſhould be rais'd a Foot or more above the Level of the Ground. In *February* their Buds will appear above-ground, and if the Weather be mild, they will advance in Height very faſt, and in *March* they will produce their Flowers; but as their Stems grow tall, and the Spring-ſeaſon being commonly windy, it will be very proper to ſupport them with Sticks, to prevent their being broke down: Nor ſhould the Flowers of this Plant be gather'd when blown, for it greatly weakens their Roots; ſo that they do not afford an Increaſe of Bulbs, and many Times are two or three Years before they flower again.

Theſe Roots ſhould be tranſplanted every third Year, by which Time they will have furniſh'd ſome Off-ſets of conſiderable Strength, which muſt be taken from the old Roots; and ſuch of them as are large enough to produce Flowers, may be planted in Borders with the old Roots, but the ſmall ones ſhould be planted in a Nurſery-bed, where they may remain till they have Strength enough to flower; but if you remove the Blowing Roots oftener, they will not flower ſo ſtrong, nor will their Increaſe be near ſo great.

This Plant deſerves a Place in the moſt curious Flower Gardens, for the Earlineſs of its Flowering; it being the firſt Plant of large Growth that we have flowers, and ſo conſequently garniſhes the Crowns of Borders, at a Seaſon when there are no other Flowers in the ſame Line appearing, and ſo begins that Order of Flowering, which ſhould be ſucceeded by other Flowers of the like Growth, through the greateſt part of the Seaſon. Their Seeds are ripe about the Beginning of *June*, and ſhould be ſown in *July*. For the Manner of performing it, ſee *Tulipa*.

CORONA SOLIS; The Sun-Flower.

The *Characters* are;

It hath a ſquamous Cup; the Flowers are radiated like the great Starwort; *the Embryo's of the Seeds are diſtinguiſh'd by little imbricated Leaves in the Diſk; the Top of the Ovary is crown'd with two ſmall Leaves; the Seeds are puſh'd out from the Bottom of the Flower, leaving a Vacuity which appears very like a Honey-comb.*

The *Species* are;

1. CORONA SOLIS. *Tab.* The Common great annual Sun-Flower.

2. CORONA SOLIS *maxima, ſemine albo, cinereo & ſtriato. Tourn.* Great annual Sun-Flower, with Aſh-colour'd ſtrip'd Seeds.

3. CORONA SOLIS *maxima, flore pallide ſulphureo, fere albo, ſemine nigro. Boerh. Ind.* Great annual Sun-Flower, with pale Brimſtone-colour'd Flowers, and black Seeds.

4. CORONA SOLIS *maxima, flore pleno aureo, ſemine nigro. Boerh. Ind.* Great annual Sun-Flower with double yellow Flowers, and black Seeds.

5. CORONA SOLIS *maxima, flore pleno aureo, ſemine albo. Boerh. Ind.* Great annual Sun-Flower with double yellow Flowers, and white Seeds.

6. CORONA SOLIS *maxima, flore pleno ſulphureo, ſemine nigro. Boerh. Ind.* Great annual Sun-Flower, with double Brimſtone-colour'd Flowers, and black Seeds.

7. CORONA SOLIS *maxima, flore pleno ſulphureo, ſemine albo. Boerh. Ind.* Great annual Sun-Flower, with double Brimſtone-colour'd Flowers, and white Seeds.

8. CORONA SOLIS *perennis & vulgaris. Vaill.* Common Perennial or Everlaſting Sun-Flower, *vulgo*.

9. CORONA SOLIS *foliis amplioribus laciniatis. Tourn.* Perennial Sun-Flower, with large divided Leaves.

10. CORONA SOLIS *foliis anguſtioribus laciniatis. Tourn.* Perennial Sun-Flower, with narrow divided Leaves.

11. CORONA SOLIS *foliis aſperis, tribus vel quaternis ad genicula ſitis. Mor. Hiſt.* Rough-leav'd Perennial Sun-Flower, having three or four Leaves plac'd at each Joint of the Stalk.

12. CORONA SOLIS *trachelii folio, radice repente. Tourn.* Creeping-rooted Perennial Sun-Flower, with a Throat-wort Leaf.

13. CORONA SOLIS *altiſſima, Voſacan dicta. Vail.* The talleſt Perennial Sun-Flower, *call'd* Voſacan.

14. CORONA SOLIS *altiſſima, virgæ aureæ foliis. Tourn.* Talleſt Perennial Sun-Flower, with Golden-Rod Leaves.

15. CORONA SOLIS *ſalicis folio, alato caule. Tourn.* Willow-leav'd Perennial Sun-Flower with winged Stalks.

16. CORONA SOLIS *ſalicis folio latiore, caule alato ſerotino.* Broader Willow-leav'd Perennial late flowering Sun-flower, with winged Stalks.

17. CORONA SOLIS *arborea, folio latiſſimo platani. Boerh. Ind.* Tree-like Perennial Sun-Flowers, with a broad Plane-tree Leaf.

18. CORONA SOLIS *parvo flore, tuberoſa radice. Tourn.* Tuberoſe-rooted Perennial Sun-Flower, with a ſmall Flower, *commonly call'd* Jeruſalem Artichoke.

All theſe *Species* of *Sun-Flowers* are Natives of *America*, from whence we are often ſupply'd with new Kinds, it being a large *Genus* of Plants: And it is very remarkable, that there is not a ſingle *Species* of this *Genus* that is *European*; ſo that before *America* was diſcover'd, we were wholly unacquainted with theſe Plants. But altho' they are not originally of our own Growth; yet are they become ſo familiar with our Climate, as to thrive and increaſe full as well as if they were at Home (ſome of the very late Flowering Kinds excepted, which require a longer Summer than we generally enjoy, to bring them to Perfection): and many of them are now ſo plentiful in *England*, that Perſons unacquainted with the Hiſtory of theſe Plants, would imagine them at leaſt to have been Inhabitants of this Iſland many hundred Years; particularly the *Jeruſalem Artichoke*, which tho' it doth not produce Seeds in our Climate, yet doth ſo multiply by its knobbed Roots, as when once well fix'd in a Garden, is not eaſily to be rooted out.

The firſt ſeven Sorts being Annual, muſt be ſown every Spring in a Bed of good light Earth; and when the Plants are come up about three Inches high, muſt be tranſplanted into Nurſery-beds, at about eight or ten Inches Diſtance every way, where they may continue until they are a Foot high, when they muſt be carefully taken up with a Ball of Earth, and tranſplanted into the Middle of large Borders, or intermix'd in Boſquets of large growing Plants, obſerving to water them until they are well rooted; after which Time they will require no farther Care but to clear them from Weeds.

In *July* the great Flowers upon the Tops of the Stems will appear; amongſt which, the beſt and moſt double Flowers of each kind ſhould be preſerv'd for Seeds; for thoſe which flower

later

later upon the Side-branches are neither ſo fair, nor do they perfect their Seeds ſo well as thoſe which are firſt in Flower: When the Flowers are quite faded, and the Seeds are form'd, you ſhould carefully guard the Heads from the Sparrows, which will otherwiſe devour moſt of the good Seeds; and about the Beginning of *October*, when the Seeds are ripe, you ſhould cut off the Heads with a ſmall Part of the Stems, and hang them up in a dry airy Place for about a Month; by which Time the Seeds will be perfectly dry and hard, when you may eaſily rub them out, and put them up in Bags, or Papers, preſerving them from Vermin until the Seaſon for ſowing them.

The other perennial Sorts rarely produce Seeds in *England*, but moſt of them do increaſe very faſt at their Roots, eſpecially the common and creeping-rooted Kinds. The eighth Sort, which is the moſt common in the *Engliſh* Gardens, is the largeſt and moſt valuable Flower, and is a very proper Furniture for large Borders in great Gardens, as alſo for Boſquets of large growing Plants, or to intermix in ſmall Quarters with Shrubs, or in Walks under Trees where few other Plants will thrive: It is alſo a great Ornament to Gardens within the City; where it doth grow in Defiance of the Smoak better than moſt other Plants; and for its long Continuance in Flower, deſerves a Place in moſt Gardens, for the Sake of its Flowers for Baſons, *&c.* to adorn Halls and Chimnies in a Seaſon when we are at a Loſs for other Flowers. It begins flowering in *June*, and continues until *October*.

The 9th, 10th, 11th, 12th, 13th, 14th, 15th and 16th Sorts, may alſo have a Place in ſome abject Part of the Garden, for the Variety of their Flowers; which though not ſo fair as thoſe of the common Sort, yet will add to the Diverſity; and as many of them are late Flowerers, ſo we may continue the Succeſſion of Flowers longer in the Seaſon.

Theſe Sorts are all of them very hardy, and will grow in almoſt any Soil or Situation: They are propagated by parting their Roots into ſmall Heads, which in one Year's Time will ſpread and increaſe greatly. The beſt Seaſon for this Work is in the Middle of *October*, ſoon after their Flowers are paſt, or very early in the Spring, that they may be well rooted before the Droughts come on; otherwiſe their Flowers will be few in Number, and not near ſo fair, and by this means their Roots will be weak; but if they are planted in *October*, you will ſave the Trouble of watering them; their Roots being ſurely fix'd before the dry Weather, they will need no other Trouble than to clear them from Weeds.

The *Jeruſalem Artichoke* is propagated in many Gardens for the Roots, which are by ſome People as much eſteem'd as *Potatoes*, but they are more watery and flaſhy, and are very ſubject to trouble the Belly by their windy Quality, which hath brought them almoſt into Diſuſe.

Theſe are propagated by planting the ſmaller Roots, or the larger ones cut into Pieces, (obſerving to preſerve a Bud to each ſeparate Piece) either in the Spring or Autumn, allowing them a good Diſtance, for their Roots will greatly multiply; the Autumn following, when their Stems decay, the Roots may be taken up for Uſe. Theſe ſhould be planted in ſome remote Corner of the Garden, for they are very unſightly while growing, and their Roots are apt to over-run whatever grows near them, nor can they be eaſily deſtroy'd when they are once well fix'd in a Garden.

The ſeventeenth Sort, is ſomewhat tenderer than any of the former, and doth therefore require a better Situation, and a dry Soil. This Sort ſeldom produces its Flowers fair with us, it being a very late Flowerer; and if the Autumn proves bad, doth not produce any Flowers: This will grow to be ſix, ſeven, or eight Feet high, and very ſtrong, but there is no great Beauty in its Flowers, and is rarely preſerv'd except in *Botanick* Gardens.

[**CORONILLA**; [This Plant is ſo call'd of *Corona*, a *Crown* or *Garland*, q. d. a *little Crown*, &c. becauſe it bears Huſks at the End like a little Crown, or becauſe it reſembles the Garlands that Shepherds adorn'd their Sweet-hearts with: It is by ſome call'd *Colutea*] Jointed-podded Colutea.

The *Characters* are;

It hath Leaves like thoſe of the Scorpion-Sena; *the Flowers are papilionaceous, the Pods are full of Joints, having one oblong ſwelling Seed in each Diviſion.*

The *Species* are;

1. CORONILLA *argentea Cretica.* *Tourn.* Silver-leav'd jointed-podded Colutea of Candia.
2. CORONILLA *maritima, glauco folio.* *Tourn.* Maritime jointed-podded Colutea, with a Sea-green-Leaf.
3. CORONILLA *herbacea, flore vario.* *Tourn.* Herbaceous jointed-podded Colutea, with a variable Flower.
4. CORONILLA *Cretica herbacea, flore parvo purpuraſcente.* *Tourn.* *Candia* herbaceous, jointed-podded Colutea, with a ſmall purpliſh Flower.
5. CORONILLA *Zeylanica argentea tota.* *Boerh. Ind.* Silver jointed-podded Colutea of *Ceylon*.
6. CORONILLA *minima.* *Tourn.* The leaſt jointed-podded Colutea.
7. CORONILLA *ſiliquis & ſeminibus craſſibus.* *Tourn.* Jointed-podded Colutea, with thick Pods and Seeds.
8. CORONILLA *Americana ſcandens pentaphylla.* *Plum.* Five-leav'd *American* jointed-podded Colutea, with climbing Stalks.

The firſt and ſecond *Species* grow with us to be ſmall Shrubs about three or four Feet high, and are ſo nearly alike in all reſpects, ſo far as I have been able to examine them, that I could readily pronounce them the ſame, were it not that they have been by ſo many eminent *Botaniſts* diſtinguiſh'd for two abſolutely different Plants, which if there are two ſuch, I have as yet ſeen but one of them: I have indeed receiv'd Seeds of the two Sorts from different Perſons Abroad; but when they came up, they prov'd the ſame, and this more than once; which cauſes me to ſuſpect they are not different; for at different Seaſons of the Year the ſame Plant appears different as to the Colour of their Leaves; which might at firſt lead a Perſon into the Miſtake: and this has been follow'd by all that have ſince wrote thereof.

This Plant is propagated by ſowing the Seeds in the *Spring*, either upon a gentle Hot-bed or on a warm Border of light freſh Earth; and when the Plants are come up about two Inches high, they ſhould be tranſplanted either into Pots, or in a Bed of good rich Earth, at about four or five Inches Diſtance every way, where they may remain until they have obtain'd Strength enough to plant out for good, which ſhould be either into Pots fill'd with good freſh Earth, or in a warm ſituated Border; in which, if the Winter is not too ſevere, they will abide very well, and in the *Spring* following will produce large Quantities of yellow Flowers of a ſtrong ſweet Smell; which will be ſucceeded by long ſlender-jointed Pods in great Plenty, in which are contain'd the Seeds.

The third Sort dies down every *Winter*, but riſes again the ſucceeding *Spring*, and produces large trailing Branches, which are furniſh'd with great Numbers of variable-colour'd Flowers, which grow in Bunches; theſe are ſometimes ſucceeded by ſmall-jointed Pods, containing many oblong Seeds: but the Root creeps very far under-ground, by which the Plant increaſes greatly; which when permitted to remain unremov'd for two or three Years, will ſpread and over-bear whatever Plants grow near it; for which Reaſon the Roots ſhould be confin'd; and it ſhould be planted at a Diſtance from any other Plants: It will grow in almoſt any Soil and Situation, but thrives beſt in a warm Sunny Expoſure, in which the Flowers will alſo be much fairer, and in greater Quantities.

The fourth Sort is Annual, and muſt be ſown every *Spring* in an open Bed or Border of good light Earth, in the Place where it is to remain; for it doth not very well bear removing. This is a Plant of little Beauty, and is only preſerv'd in curious Gardens of Plants.

The fifth Sort is very tender, being a Native of *Ceylon*: This muſt be ſown on a Hot-bed early in the *Spring*; and when the Plants are come up, they muſt be tranſplanted into ſmall Pots fill'd with light ſandy Earth, and plung'd into a freſh Hot-bed of Tanners Bark; obſerving to give them frequent gentle Waterings: and as the Weather is hot or cold, ſo they muſt have more or leſs Air in Proportion thereto, by raiſing up the Glaſſes in the Middle of the Day, but in the Nights the Glaſſes ſhould be cover'd with Mats.

And when the Plants have grown ſo as to fill the Pots with their Roots, they muſt be carefully ſhaken out of them, preſerving the Earth to their Roots; and after their having pared off the Outſide of the Ball of Earth, put them into Pots a Size bigger than thoſe were which they came out of, filling up the Pot with the ſame light freſh ſandy Earth as before; then plunge the Pots again into the Hot-bed, and manage them as before. In the *Winter* they muſt be plac'd in a warm Bark-Stove amongſt Plants of the tendereſt Claſs, obſerving to refreſh them frequently with Water which has ſtood in the ſame Stove at leaſt eight or ten Hours before, that the Cold may be taken off: but never give them too much at a time: In this Management I have had this Plant ſucceed very well for two or three Years; but I have not as yet ſeen it flower in *England*, tho' there are Plants of this Kind in three or four Gardens, which are two or three Years old.

The ſixth Sort is a very ſmall Plant, and hath very little Beauty in it; this is preſerv'd by the Curious in Botany, but is ſeldom found in Gardens of Pleaſure, where few Plants are admitted that are not either beautiful or rare; and it is propagated by ſowing of the Seeds in the *Spring*, on a Bed of freſh ligh light Earth in a warm Poſition: And when the Plants are come up, they muſt be either tranſplanted into Pots fill'd with the ſame freſh Earth, or into warm Borders under a South or Weſt Wall; for they are ſubject to be deſtroy'd by ſevere Froſts: and therefore thoſe which are planted in Pots ſhould be ſhelter'd during the Winter-ſeaſon under a common Hot-bed Frame, taking off the Glaſſes in mild Weather, that they may enjoy as much of the free open Air as poſſible; and in the *Spring*, after the Cold is paſt, they may be ſhaken out of the Pots, and planted in a warm Border, where they will flower and produce ripe Seeds the ſucceeding *Summer*.

The ſeventh Sort grows to the Height of two or three Feet, and branches out on every Side, ſo as to form a regular Shrub. This may be propagated by Seeds, which ſhould be ſown on a moderate Hot-bed in the Spring; and when the Plants are about two Inches high, they ſhould be carefully tranſplanted into ſmall Pots, filled with light freſh Earth, and plunged into a very moderate Hot-bed, being careful to ſcreen them from the Sun until they have taken new Root; after which Time they muſt have a large Share of freſh Air, otherwiſe they will draw up very weak; they muſt alſo be frequently watered in warm Weather. When theſe Plants have acquired Strength, they ſhould be inured to bear the open Air by degrees; for in Summer they ſhould be taken out of the Hot-bed, and ſome of them may be planted in warm Borders; but it will be proper to keep ſome in Pots, that they may be ſheltered in Winter; for in ſevere Froſt, thoſe in the Borders will be in danger of ſuffering thereby. Theſe Plants produce their Flowers in the Spring, when they make an agreeable Appearance, and in *Auguſt* they perfect their Seeds.

The eighth Sort was diſcovered by Father *Plumier* in *America*. I received the Seeds of this Plant from *Carthagena*, which was ſent me by my late ingenious Friend Doctor *William Houſtoun*. This Plant is propagated by Seeds, which ſhould be ſown early in the Spring on a moderate Hot-bed; and when the Plants are come up, they ſhould be each tranſplanted into a Halfpenny Pot, filled with freſh rich Earth, and plunged into a Hot-bed of Tanners-bark, obſerving to ſhade them until they have taken Root; after which time they ſhould have Air and Water in Proportion to the Warmth of the Seaſon; and when they have filled theſe Pots with their Roots, they ſhould be ſhifted into Pots of a larger Size, and plunged into the Hot-bed again, where they muſt remain until Autumn, when they ſhould be removed into the Stove, and plunged into the Tan. Theſe Plants muſt be conſtantly kept in the Bark-ſtove, and placed among Plants which require a moderate Heat; where they will thrive and flower, and ſhould be ſupported by tall Sticks, round which they will twine, as Hops do; ſo that they muſt not be ſuffered to twiſt round other Plants, leſt they over-bear and ſpoil them. Theſe are very proper Plants to place againſt an Eſpalier on the Back-part of the Stove, amongſt other climbing Plants, where they will make an agreeable Variety.

This Sort will continue two or three Years, provided it be carefully managed, and will ſometimes produce ripe Seeds in this Country; but it will be proper to lay down ſome of the Shoots, either into the Tan, or Pots of freſh Earth plunged into the Tan, becauſe theſe will often take Root, whereby a Supply of young Plants may be obtained; which is a ſure Method to preſerve the Kind in this Country, where they do not commonly perfect their Seeds.

CORONOPUS; [Κορωνόπȣς, of Κορώνη a *Crow*, and Πȣ͂ς a *Foot*; becauſe the Leaves are ſaid to reſemble the Foot of a Crow.] Buck's-horn Plantain.

The *Characters* are;

It agrees in Flower and Fruit with the Plantain, *from which it differs in its Leaves, which are deeply cut in on the Edges; whereas the Leaves of* Plantain *are either intire, or but ſlightly indented.*

The *Species* are;

1. Coronopus *hortenſis. C. B.* Garden Buck's-horn Plantain or Hart's-horn, *vulgo*.
2. Coronopus *Maſſilienſis hirſutior latifolius. Tourn.* Broad-leav'd hairy Buck's-horn Plantain of *Marſeilles*.
3. Coronopus *Neapolitanus tenuifolius. Col.* Narrow-leav'd Buck's-horn Plantain of *Naples*.
4. Coronopus *maritimus roſeus. Bocc. Rar. Pl.* Roſe-like Sea Buck's-horn Plantain.

The firſt of theſe *Species*, tho' intitled a Garden Plant, yet is found wild in moſt Parts of *England*, and is the very ſame Plant which grows upon moſt Commons and barren Heaths, where, from the Poorneſs of the Soil, it appears to be very different from the Garden Kind, as being little more than a fourth Part ſo large. But this Plant, when tranſplanted or ſown in a Garden by the other, grows to be full as large. Nor can I ſee any Difference between theſe, and that which grows upon the Sea-Coaſts; tho' *Caſpar Bauhin*, and many Botaniſts after him, make them diſtinct Species: But when they are all cultivated together in the ſame Soil, I am ſatisfy'd that no one Perſon can diſtinguiſh them, therefore I make no doubt of calling them all the ſame Plant.

This *Species* was formerly cultivated in Gardens as a Sallad-Herb; but at preſent is little regarded, and almoſt wholly diſuſed: It may be eaſily cultivated by ſowing the Seeds in the Spring upon any Soil, or in any Situation, it being extremely hardy; and when it comes up, it may be thinned out and ſuffered to remain for Uſe at about three or four Inches Diſtance, where the Leaves may be often cut for the Purpoſes above-mentioned, the Roots ſtill putting forth freſh Leaves; and if it is not ſuffered to ſeed, the Roots will remain two or three Years: But it ſeldom continues long after perfecting its Seeds. If the Seeds are ſuffered to fall upon the Ground, there will be a conſtant Supply of Plants, without any farther Care than clearing them from Weeds as they grow. The other Varieties are maintained in Botanick Gardens, but are ſeldom cultivated for Pleaſure or Profit.

CORTUSA: [This Plant is ſo called, from *Cortuſus*, a famous Botaniſt, who firſt brought it into Uſe.] Bear's-Ear Sanicle.

The *Characters* are;

It hath a perennial Root; the Leaves are roundiſh, rough, and crenated on the Edges, like thoſe of Ground-Ivy; *the Cup of the Flower is ſmall, and divided into five Parts; the Flowers are ſhaped like a Funnel, are cut at the Top into many Segments, and are diſpoſed in an Umbel; the Fruit is roundiſh, terminating into a Point, and is cloſely fixed in the Cup, in which are contained many ſmall angular Seeds.*

There is but one *Species* of this Plant at preſent in *England*, which is;

Cortusa *Matthioli. Cluſ.* The Bear's-Ear Sanicle, or *Cortuſa* of *Matthiolus*.

This Plant is nearly ally'd to the *Auricula Urſi*; but the Flowers are not quite ſo large and fair: yet, for its Curioſity, may deſerve a Place in every good Garden, eſpecially as it requires no great Management to preſerve it: for it being a Native of the *Alps*, will grow in the coldeſt Part of the Garden, under North-Walls, *&c.* but muſt not be planted under the dropping of Trees, nor in two wet or ſtiff Soil. It is propagated by parting the Roots, in the manner of *Auricula's*; the beſt Seaſon for which is about *Auguſt* or *September*. Theſe Plants loſe their Leaves in Winter, but put out new ones early in the Spring; and in *April* they produce their Flowers, which are ſometimes ſucceeded by Seed-Pods; but it is very rare that they perfect their Seeds with us.

CORYLUS, [is ſo call'd, of Καρύα a *Nut*, q. d. a *little Nut*. It is alſo call'd *Avellana*, as tho' *Abellina*, of *Abella* a Town in *Campania*, where it grew in great Plenty.] The Hazel or Nut-tree.

The *Characters* are;

It hath Male Flowers (or Katkins) growing at remote Diſtances from the Fruit on the ſame Tree; the Nuts grow (for the moſt part) in Cluſters, and are cloſely joined together at the Bottom, each being covered with an outward Huſk or Cup, which opens at the Top; and when the Fruit is ripe, it falls out; the Leaves are roundiſh and intire.

The *Species* are;

1. Corylus *ſylveſtris. C. B.* The wild Hazel-Nut.
2. Corylus *ſativa, fructu albo minore, ſive vulgaris. C. B.* The ſmall manured Hazel-Nut.
3. Corylus *ſativa, fructu rotundo maximo. C. B.* The large Cob-Nut.
4. Corylus *ſativa, fructu oblongo rubente. C. B.* The Red Filbert.
5. Corylus *ſativa, fructu oblongo rubente, pellicula alba tecto. C. B.* The white Filbert.
6. Corylus *Hiſpanica, fructu majore anguloſo. Pluk. Alm.*

The firſt of theſe Trees is common in many Woods in *England*, from whence the Fruit is gather'd in Plenty, and brought to the *London* Markets by the Country People. This Tree is ſeldom planted in Gardens, (except by Perſons curious in Collections of Trees and Shrubs): It delights to grow on a moiſt ſtrong Soil, and may be plentifully increaſ'd by Suckers from the old Plants, or by laying down their Branches, which in one Year's Time will take ſufficient Root for tranſplanting; and theſe will be much handſomer, and better rooted Plants than Suckers, and will greatly out-grow them, eſpecially while young.

The ſecond and third Sorts are planted in Hedge-rows, in moiſt ſhady Places in Gardens: but the Fruit is much better, and in greater Quantities, when they have an open, free Air, and are not ſuffer'd either to grow too thick, or be over-hung or crowded with other Trees.

The fourth and fifth Sorts, *viz.* the *Red* and *White Filberts*, are moſtly eſteem'd for their Fruit, being much ſweeter, and their Shells much tenderer.

The ſixth Sort is annually brought from *Spain* in great Plenty, and ſold in *London* all the Winter-ſeaſon; from which Nuts there have been many Trees raiſ'd in the *Engliſh* Gardens; but they ſeldom prove the ſame with the Nuts ſown.

All theſe Sorts may be propagated by ſowing their Nuts in *February*; which, in order to preſerve them good, ſhould be kept in Sand in a moiſt Cellar, where the Virgin can't come at them to deſtroy them: Nor ſhould the external Air be excluded from 'em, which would occaſion their growing mouldy.

The Manner of ſowing the Seeds being well known to every one, I need not here mention it, eſpecially ſince it is not the ſureſt Way to obtain the Sorts deſired; for they ſeldom prove ſo good as the Nuts which were ſown, or at leaſt not one in four of them will: And the Method of propagating them by *Layers* being not only the ſureſt, but almoſt expeditious, is what I would recommend to every one, who would cultivate theſe Trees for the ſake of their Fruits.

CORYMBIFEROUS PLANTS, are ſuch as have a compound diſcous Flower; but their Seeds have no Down adhering to them. The Name is taken from the manner of bearing its Flowers in Cluſters, and ſpreading round in the Form of an Umbrella, as *Onions*, &c. Of this Kind is the *Corn Marygold*, *common Ox-Eye*, the *Daiſy*, *Camomile*, *Mugwort*, *Feverfew*, &c.

Mr. *Ray* diſtinguiſhes them in ſuch as have a radiate Flower, as the *Sun-Flower*, the *Marygold*, &c. and ſuch as have a naked Flower, as the *Lavender Cotton* and *Tanſey*; and alſo thoſe that are akin to them, as *Scabious*, the *Teaſel*, *Carduus*, &c.

CORYMBUS, [Κόρυμβος, Gr.] ſignifies among *Botaniſts* Cluſters of Berries, as thoſe of *Ivy*.

Jungius uſes it, to ſignify the Extremity of a Stalk, ſo ſubdivided and laden with Flowers or Fruits, as to compoſe a ſpherical Figure.

It is alſo by modern *Botaniſts* us'd to ſignify a compound diſcous Flower, which does not fly away in Down, as the *Chryſanthemum*. *Daiſy*, *Chryſocome*, &c. for theſe kind of Flowers being ſpread into Breadth, do, after a ſort, reſemble an Umbrella, or Bunch of Ivy-Berries.

COTINUS CORIARIA, Venice Sumach.

The *Characters* are;

It hath round Leaves, with long Foot-ſtalks; the Flowers are ſmall, conſiſting of five Leaves, which expand in Form of a Roſe; *are diſpos'd in capillary Branches of very ſlender and ſtiff Filaments or Hairs, which are widely diffus'd after the manner of Plumes, and ſpring out of the top Branches.*

There is but one *Species* of this Plant at preſent known, and that is,

Cotinus *Coriaria. Dod.* Venice Sumach, *commonly call'd* Coccygria.

This Shrub grows with us about ſeven or eight Feet high: The Branches grow very irregular and diffus'd; but when it flowers, (which it ſeldom doth until it is pretty ſtrong) it maketh a beautiful Figure, the Flowers growing, as it were, on large Plumes of Hair, which almoſt cover the whole Shrub: It is very proper to plant amongſt other Shrubs of the ſame Growth, where it will make an agreeable Variety.

This Plant is propagated by laying down the tender Branches, which ſhould have a little Slit made at one of the Joints that are laid in the Earth, (as is practiſ'd in laying *Carnations*) which will greatly facilitate their Rooting. When they are ſufficiently rooted, (which is commonly in one Year's Time) they may be tranſplanted, where they are to remain; for it ſeems not to bear removing well, eſpecially when grown old; the Roots trailing far under-ground, which, when cut or broken, do not ſoon recover it; and it ſeldom produces many Fibres near the Stem.

The Wood of this Shrub is greatly us'd in the Southern Parts of *France*, where it grows in great Plenty, to dye their Woollen Cloths of a yellow Colour, or *Feuille Morte*; and the Tanners uſe the Leaves to prepare their Skins.

COTONEA MALUS. *Vide* Cydonia.

COTONEASTER. *Vide* Meſpilus.

COTULA FOETIDA. *Vide* Chamæmelum Fœtidum.

COTYLEDON [Κοτυληδὼν, Gr. of Κοτυλὴ, Gr. a *Cavity*; becauſe the Leaves of this are cavated, or becauſe it reſembles a Veſſel wherewith the Ancients us'd to draw Water, or the Hollow of the Thigh.] Navel-wort.

The *Characters* are;

It hath a Leaf, Stalk, and the whole Appearance of Houſeleek; from which it differs in having an oblong tubulous Flower conſiſting of one Leaf, which is divided at the Top into five Parts; the Fruit is like that of the Houſeleek.

The *Species* are;

1. Cotyledon *major. C. B.* The greater Navel-wort.

2. Cotyledon *Africana fruteſcens, foliis orbiculatis, limbo purpureo cinctis. Tourn.* Shrubby *African* Navel-wort, with round Leaves edg'd with a purple Rim.

3. Cotyledon *Africana fruteſcens, folio longo & anguſto, flore flaveſcente. Com. Rar.* Shrubby *African* Navel-wort, with a long narrow Leaf, and a yellowiſh Fower.

4. Cotyledon *Africana fruteſcens, flore umbellato, coccineo. Com. Rar.* Shrubby *African* Navel-wort, with ſcarlet Flowers growing in an Umbel.

5. Cotyledon *Afra, folio craſſo lato laciniato, floſculo aureo. Boerh. Ind.* *African* Navel-wort, with a broad thick divided Leaf, and ſmall yellow Flowers.

6. Cotyledon *Afra arboreſcens major, foliis glaucis oblongioribus, flore luteo. Boerh. Ind.* Greater Tree-like *African* Navel-wort, with oblong Sea-green Leaves, and a yellow Flower.

7. Cotyledon *major arboreſcens Afra, foliis minoribus, craſſiſſimis, viridioribus, minutiſſime punctatis. Boerh. Ind.* Greater *African* Tree-like Navel-wort, with ſmall thick Leaves.

8. Cotyledon *major arboreſcens Afra, foliis minoribus oblongis, atro-viridibus. Boerh. Ind.* Greater *African* Tree-like Navel-wort, with ſmall oblong dark green Leaves.

9. Cotyledon *major arboreſcens Afra, foliis orbiculatis glaucis, limbo purpureo & maculis viridibus ornatis. Boerh. Ind. alt.* Greater Tree-like *African* Navel-wort, with rounder Sea-green Leaves, having purple Edges, and ſpotted with Green.

10. Cotyledon *Capenſis, folio ſemiglobato. Hort. Elth.* Navel-wort of the *Cape of Good Hope*, with thick half-globular Leaves.

The firſt Sort (which is that us'd in Medicine) grows upon old Walls and Buildings in divers Parts of *England*, but is not readily to be cultivated in a Garden; it requires a dry rubbiſhy Soil, and to have a ſhady Poſition.

The *African* Kinds are all of them propagated by planting Cuttings in any of the Summer Months, which ſhould be laid in a dry Place for a Week or more after they are taken from the Plant, before they are planted; for theſe abound with Juice through every Part of the Plant, which will certainly rot the Cuttings, if they are not ſuffer'd to lie out of the Ground, that the wounded Part may heal over, and the great Redundancy of Sap evaporate. The Soil in which theſe Plants thrive beſt, is one third freſh light Earth from a Paſture, one third Sand, and the other third Part Lime Rubbiſh, and rotten Tan, in equal Quantities: Theſe ſhould be well mix'd, and laid in a Heap ſix or eight Months before it is us'd, turning it over five or ſix times, that the Parts may the better incorporate; and before it is us'd, it will be proper to paſs it through a Screen, to ſeparate the large Stones and Clods, *&c.* therefrom.

Having prepar'd the Earth, and your Cuttings being in a fit Order for Planting, you muſt fill as many half-penny Pots with Earth as you have Cuttings to plant; then put one Cutting in the middle of each Pot about two Inches deep or more, according to their Strength; then give them a little Water to ſettle the Earth cloſe about them, and ſet the Pots in a warm ſhady Place for about a Week, to prepare the Cuttings for putting forth Roots; after which they ſhould be plung'd into a moderate Hot-bed of Tanners Bark, which will greatly facilitate their rooting; but obſerve to give them Air, by raiſing the Glaſſes at all times when the Weather will permit, as alſo to ſhade the Glaſſes in the Heat of the Day.

In about a Month's Time after planting, theſe Cuttings will be rooted, when you muſt begin to expoſe them to the open Air by degrees, firſt drawing the Pots out of the Tan, and ſetting them on the Top; then raiſe the Glaſſes very high in the Day-time; and in about a Week after remove the Pots into a Green-houſe, and there harden them for another Week; after which they may be expos'd to the open Air in a well defended Place, obſerving not to ſet them into a Place too much expos'd to the Sun, until they have been enur'd to the open Air for ſome Time.

In this Place the Plants may remain until the beginning of *October*; at which Time you ſhould remove them into the Conſervatory, placing them as near the Windows as poſſible at firſt, letting them have as much free open Air as the Seaſon will permit, by keeping the Windows open whenever the Weather is good: And now you muſt begin to abate your Waterings, giving it to them ſparingly, eſpecially the fifth Sort, which is ſo very ſucculent, that upon its having a little too much Water in Winter, it will certainly rot; but you ſhould not ſuffer its Leaves to ſhrink for want of Moiſture, which is another Extreme ſome People run into for want of a little Obſervation; and when they are ſuffer'd to ſhrink for want of Water, they ſeldom fail to rot when they have Water given them, for their Parts being conſtricted for want of ſufficient Moiſture to keep their Veſſels diſtended, they are render'd incapable of diſcharging this Moiſture whenever they receive it again. This Sort ſhould be placed in a warm Stove in Winter, nor muſt it be ſet abroad in Summer, for it is much tenderer than any of the other Sorts.

The other Plants are all of them pretty hardy, except the ſixth Sort, (which muſt have a moderate Stove in Winter) and may be preſerv'd without any artificial Heat in the Winter. The beſt Method to treat theſe Plants is, to place them in an open airy dry Glaſs-Frame among *Ficoides's* and *African Houſeleeks*, where they may enjoy as much of the Sun-ſhine as poſſible, and have a free dry open Air; for if theſe are plac'd in a common Green-houſe amongſt ſhrubby Plants, which perſpire freely, it will fill the Houſe with a damp Air, which theſe ſucculent Plants are apt to imbibe; and thereby becoming too replete with Moiſture, do often caſt their Leaves, and many times their Branches alſo decay, and the whole Plant periſhes.

The fifth Sort, as was before mention'd, muſt be preſerv'd in a moderate Stove, with *Aloes*, *Cereus's*, &c. which may be kept up to the temperate Heat as mark'd on Mr. *Fowler's Thermometers*: This muſt have very little Water in Winter, and be planted in a very dry ſandy Soil.

The fourth Sort produces the moſt beautiful Flowers of any of them, and deſerves a Place in every good Collection of Plants; as doth the ſecond, third, fifth and ſixth, for the regular Beauty of their Stems, and large, fair, thick ſucculent Leaves; and the ſecond, third, and ſixth Sorts produce very fair, handſome Bunches of Flowers, but they ſeldom produce Seeds in *England*.

The ninth Sort uſually grows to the Height of two or three Feet in this Country, and divides into many Branches: It is eaſily propagated by Cuttings in any of the Summer Months, if, after they are taken from the Plants, they are laid in a dry Place for a Week or ten Days, that the wounded Parts may heal before they are planted; otherwiſe they are ſubject to rot. When the Cuttings are fit to plant, they ſhould be each put into a Half-penny Pot, filled with a Mixture of freſh Earth, Lime-rubbiſh, and Sea-ſand, in equal Proportion; then plunge the Pots into a very moderate Hot-bed, which will greatly promote their Rooting: In about ſix Weeks after Planting, the Cuttings will be well rooted, when they may be taken out of the Hot-bed, and placed in the open Air, in a Situation where they may be defended from ſtrong Winds; where they may remain till the middle of *October*, provided there happens no froſty Weather before; then they muſt be removed into an airy Glaſs-caſe, where they may be defended from the Froſt and Wet, and enjoy a large Share of freſh Air; in which Place they will thrive better than in a Green-houſe, where they cannot have ſo much free Air.

The tenth Sort is of humbler Growth, ſeldom riſing above a Foot high; this produces many ſhort Branches near the Ground, but never ſpreads very far, ſo may be confined in ſmall Pots. This is propagated in the ſame Manner as the former Sort, and ſhould be treated in the ſame Method.

COURBARIL, [*This is the* American *Name by which the* Indians *call this Tree.*] The Locuſt-tree, *vulgo*.

The *Characters* are;

It hath a papilionaceous Flower, from whoſe Calyx ariſes the Pointal; which afterward becomes a unicapſular hard Pod, including roundiſh hard Seeds, which are ſurrounded with a fungous ſtringy Subſtance.

We know but one *Specie* of this Plant, *viz.*

COURBARIL *bifolia, flore pyramidato. Plum. Nov. Gen.* Courbaril with two Leaves ſet together, and a pyramidal Flower, commonly called *Locuſt-tree*, by the *Engliſh* Inhabitants of *America*.

The Pods of this Tree are frequently brought from *America*, by the Title of *Locuſt*, from the Seeds of which theſe Plants may be raiſed. Theſe Seeds ſhould be ſown on a Hot-bed early in the Spring, and when the Plants are come up, they ſhould be very carefully taken up, and each planted into a ſmall Pot, filled with light freſh Earth, and plunged into a Hot-bed of Tanners-bark, obſerving to ſhade them until they have taken Root; after which Time they ſhould have Air and Water in proportion to the Warmth of the Seaſon; but they will not bear to be quite expoſed to the open Air in *England*, even in the hotteſt Part of Summer. In Winter theſe Plants muſt be removed into the Bark-ſtove, and plunged into the Tan, amongſt the tenderer Sorts of exotic Plants; and during that Seaſon they ſhould be frequently refreſhed with Water, but it muſt not be given to them in large Quantities, for they are impatient of much Wet. If theſe Plants are continued in the Bark-ſtove, and ſhifted into larger Pots as they increaſe in Size, they may be preſerved; but I believe it will be many Years before they will produce Flowers in *Europe*, for they are of very ſlow Growth, after the firſt ſix Months, being in this reſpect like the *Acajou*.

COWSLIP. *Vide* Primula Veris.

CRAB-TREE. *Vide* Malus.

CRAMBE; [κραμβὴ, Gr.] Sea-Cabbage.

The *Characters* are;

It hath fleſhy Leaves like thoſe of the Cabbage; the Flowers are white, conſiſting of four Leaves; the Pointal afterwards turns to a roundiſh Fruit, which terminates in a Point, having but one Cell, in which is contain'd one oblong Seed.

The *Species* are;

1. CRAMBE *maritima, braſſicæ folio. Tourn.* Sea-Cole-wort or Cabbage.
2. CRAMBE *Orientalis, dentis leonis folio, erucaginis facie. T. Cor.* Eaſtern Sea-Cole-wort, with a Dandelion Leaf, and the Face of Wild Rocket.

The firſt of theſe *Species* is found wild upon the Sea-ſhores in divers Parts of *England*, but particularly in *Suſſex* in great Plenty, where the Inhabitants gather it in the Spring to eat, preferring it to any of the *Cabbage* kind: But this muſt be gather'd young, ſoon after the Heads are thruſt out of the Ground, otherwiſe it will be very tough and rank.

This Plant may be propagated in a Garden, by ſowing the Seeds, ſoon after it is ripe, in a ſandy or gravelly Soil, where it will thrive exceedingly, and increaſe greatly by its creeping Roots, which will ſoon overſpread a large Spot of Ground, if encourag'd: This may be cut for Uſe in *April* and *May*, while it is young; but if the Heads are ſuffer'd to remain, they will produce fine regular Heads of white Flowers, which appear very handſome, and will perfect its Seeds, by which it may be propagated.

The ſecond Sort is only preſerv'd in curious Gardens of Plants for Variety, but is not of any Uſe or Beauty.

CRANE's-BILL. *Vide* Geranium.

CRASSULA, Leſſer Orpine or Houſeleek.

The *Characters* are;

It hath the Appearance of Houſeleek or Navelwort, from the latter of which it only differs in having a ſhort tubulous Flower, conſiſting of one Leaf.

The *Species* are;

1. CRASSULA *altiſſima perforata. Hort. Elth.* Talleſt Craſſula, with Leaves ſurrounding the Stalks, commonly call'd *Aloe perfoliata.*
2. CRASSULA *anacampſerotis folio. Hort. Elth.* Craſſula with an Orpine Leaf.
3. CRASSULA *portulacæ facie, arboreſcens. Hort. Elth.* Tree-like Craſſula, with the Face of Purſlain, commonly call'd the *Purſlain-Tree.*
4. CRASSULA *cæpoſa longifolia. Hort. Elth.* Onion-like Craſſula, with a long Leaf.
5. CRASSULA *cauleſcens, foliis ſempervivi cruciatis. Hort. Elth.* Stalky Craſſula, with Houſeleek-leaves.
6. CRASSULA *meſembrianthemi facie, foliis longioribus aſperis. Hort. Elth.* Craſſula with the Face of Ficoides, and long rough Leaves.
7. CRASSULA *orbicularis repens, foliis ſempervivi. Hort. Elth.* Creeping orbicular Craſſula, with Houſeleek Leaves.
8. CRASSULA *portulacæ facie, repens. Hort. Elth.* Creeping Craſſula, with the Appearance of Purſlain.

Theſe Plants are Natives of the *Cape of Good Hope*, from whence they were brought into the *European* Gardens. The firſt, third, and fifth Sorts, will grow to be ſhrubby: The firſt doth not ſend forth any Side-branches, unleſs the Top be cut off, or ſome Way injured; but it may be trained up ſix or eight Feet high, if it is ſupported with a Stake. The third Sort grows almoſt in a pyramidal Form, and the Stalks and Leaves have the Appearance of Purſlain. The fifth Sort grows very buſhy, and the Stalks are very full of Joints, and ſo brittle, that on the Touch they break, and the Pieces which fall on the Ground will take Root, ſo that it is eaſily propagated. The other Sorts are of lower Growth, moſt of them trailing on the Ground. The eighth Sort doth not continue above two Years, but it frequently ripens Seed, which if permitted to ſcatter upon the Earth in the Pots, and they are ſheltered in Winter, will produce young Plants, whereby the Kind may be eaſily preſerved.

The third Sort has not produced any Flowers in this Country, that I could ever hear; but from the Appearance of the Plant, it is ranged with theſe Plants.

All theſe Sorts may be eaſily propagated, by planting their Cuttings in any of the Summer Months, on a ſhady Border, where they will ſoon take Root, and may be then potted in a ſandy-rubbiſhing Earth; and muſt be treated in the ſame Manner as the Ficoides's, to which I ſhall refer the Reader to avoid Repetition.

CRATÆGUS; [κράταιγος, or κραταίγονον, Gr.] The Wild Service.

The *Characters* are;

The Leaves are ſingle; the Flower conſiſts of five Leaves, which expand in Form of a Roſe; the Fruit is ſmall, and ſhap'd like a Pear, in which are contain'd many hard Seeds.

The *Species* are;

1. CRATÆGUS *folio laciniato. Tourn.* The Common or Wild Service.
2. CRATÆGUS *folio ſubrotundo ſerrato, ſubtus incano. Tourn.* The white Beam-Tree, or Aria Theophraſti.
3. CRATÆGUS *ſylveſtris Anglica, foliis viburni.* The Red Cheſs Apple, or *Engliſh* Wild Service.
4. CRATÆGUS *Virginiana, foliis arbuti. Tourn.* The *Virginian* Wild Service, with Leaves like the Strawberry-Tree.

The firſt of theſe Trees is very common in divers Parts of *England*, growing in Woods, *&c.* The Leaves of this Tree are very like thoſe of the *Hawthorn*, but are larger, and have fewer Segments; the Fruit grows in Bunches, and are about the Bigneſs of *Black Cherries*, which are ſometimes ſold in the Markets in Autumn, and are by ſome People eaten as *Medlars*, &c. but have ſomewhat of an auſtere Taſte.

This Tree, where it grows wild, will ariſe to a great Height and Magnitude, but is with Difficulty tranſplanted into a Garden. The ſureſt Way to procure kindly Trees is, to ſow their Fruits ſoon after they are ripe, which muſt be manag'd in the Manner directed for the *Hawthorn*: The ſecond Spring after ſowing, the Seeds will come up, when you muſt carefully keep them clear from Weeds, and in dry Weather gently water them. In this Place the Plants may remain until the ſecond Autumn after they come up; when you muſt prepare a Spot of freſh Ground, and tranſplant them out in Rows, at about two Feet Diſtance Row from Row, and ſix Inches aſunder in the Rows, obſerving in tranſplanting them, to cut off the down-right Tap-Root, which theſe Trees are ſubject to have; and when you have planted them, cloſe the Earth about their Roots, to prevent the Froſt from turning them out of the Ground. In this Nurſery they may remain three or four Years, obſerving to keep them clear from Weeds, as alſo to dig the Ground between the Rows at leaſt once a Year, being careful not to cut or diſturb their Roots; this will greatly promote their Growth: Then you may tranſplant them where they are deſign'd to remain, which may be to form Clumps or Wilderneſſes of Trees, where, by their Variety, it will add a Pleaſure to the Proſpect: Theſe will grow to a conſiderable Bulk, if they delight in the Soil, as may be ſeen by ſeveral very large Trees now growing on *Hampſtead* Heath, therefore they ſhould be intermix'd amongſt ſuch as are of a large Growth.

The ſecond Sort is alſo very common in *England*, and will grow very regular to a conſiderable Bulk. This is eaſily propagated in a Garden, either from Layers, Suckers, or by ſowing the Seeds, as directed for the firſt Sort. This Tree deſerves a Place in large Wilderneſs Quarters, or in regular Clumps of Trees, where, by the Diverſity of its white hoary Leaves, it affords an agreeable Variety. This alſo bears its Fruit in Bunches in the Manner of the former, but is not quite ſo large, or well-taſted.

The third Sort grows wild in ſome of the Northern Counties of *England*, but is at preſent very rare near *London*. This may be propagated in the ſame Manner as was directed for the two former, and may have a Place, for Variety-ſake, in Plantations of Trees.

The *Virginian* Wild Service is ſomewhat tender while young, during which Time it will require a little Shelter, but may afterwards be tranſplanted into the full Ground, where, if it is not too much expos'd, it will thrive very well, and endure our ſevereſt Colds. This may be propagated by Seeds as the former, or from Layers and Suckers, and may alſo be budded or inarch'd into any of the former Sorts.

CRESSES, GARDEN. *Vide* Naſturtium.

CRESSES, WATER. *Vide* Siſybrium.

CRESSES, INDIAN. *Vide* Acriviola.

CRITHMUM, Samphire.

The *Characters* are;

The Leaves are thick, ſucculent, narrow, branchy, and trifid; the Flowers grow in an Umbel, each conſiſting of five Leaves, which expand in Form of a Roſe; the Empalement of the Flower becomes a Fruit conſiſting of two plain and gently ſtreak'd Seeds.

We have but one *Species* of this Plant common in *England*, which is,

CRITHMUM, *ſive fœniculum maritimum minus.* Smaller Samphire or Sea-Fennel.

This Plant grows in great Plenty upon the Rocks near the Sea-ſhore, where it is waſh'd by the Salt-water, but will not grow to any Strength in a Garden, tho' it may be preſerv'd ſeveral Years, and propagated by parting its creeping Roots in the Spring. This ſhould be planted in Pots fill'd with gravelly coarſe Soil, and in Summer plentifully water'd: In this Management it will grow tolerably well, and produce Flowers, but rarely perfects its Seeds in a Garden, nor is the Herb near ſo good for Uſe as that gathered from the Rocks. This Plant is greatly eſteem'd for pickling, and is ſometimes us'd in Medicine.

CRISTA GALLI. *Vide* Pedicularis.

CRISTA PAVONIS. *Vide* Poinciana.

CROCUS, [is ſo call'd of the Youth *Crocus*, who (as the Poets feign) loved *Smilax* with ſo violent a Paſſion, that, by reaſon of Impatience, he was turn'd into a Flower of his Name] Saffron.

The *Characters* are;

It hath a Flower conſiſting of one Leaf, which is ſhaped like a Lily, fiſtulous underneath, the Tube widening into ſix Segments, and reſting on the Footſtalk; the Pointal riſes out of the Bottom of the Flower, and is divided into three headed and creſted Capillaments; but the Empalement afterwards turns to an oblong triangular Fruit, divided into three Cells, and is full of roundiſh Seeds: To theſe Marks muſt be added, it hath a tuberoſe Root, and long, narrow, graſſy Leaves, with a longitudinal white Furrow thro' the Middle of each.

In giving a Liſt of their ſeveral Names, I ſhall divide them into two Claſſes; in the firſt of which I ſhall place all the Spring-flowering *Crocus's* nearly in the Order of their Flowering; and in the ſecond, ſhall inſert thoſe which flower in Autumn, amongſt which will come the true *Saffron.*

1. Crocus *vernus ſtriatus vulgaris. Park. Par.* The ordinary ſtriped Crocus, commonly call'd, the *Scots* Crocus.
2. Crocus *vernus luteus verſicolor primus. Park. Par.* The beſt Cloth of Gold Crocus.
3. Crocus *vernus latifolius flavus. C. B.* The *Dutch* yellow Crocus.
4. Crocus *vernus minor albicans. C. B.* Small whitiſh Spring Crocus.
5. Crocus *vernus, flore albo, purpuro-violaceo baſi. C. B.* Spring Crocus, with a white Flower, and a purple-violet Bottom.
6. Crocus *vernus latifolius, flavo-vario flore duplici. Cluſ. Hiſt.* The double Cloth of Gold Crocus.
7. Crocus *vernus latifolius flavus, flore minore & pallidiore. C. B.* Spring Crocus, with ſmaller pale yellow Flowers.
8. Crocus *vernus latifolius flavo-varius. C. B.* Spring Crocus, with yellow variable Flowers.
9. Crocus *vernus anguſtifolius, magno flore candido. C. B.* Narrow-leav'd Spring Crocus, with large white Flowers.
10. Crocus *vernus albus ſtriatus. Park. Par.* The white ſtriped Crocus.
11. Crocus *vernus albus polyanthos verſicolor. Park. Par.* The Party-colour'd Crocus, with many Flowers.
12. Crocus *vernus latifolius, flore penitus albo, ad infima tubuli parum cæruleſcente. Boerh. Ind.* White feather'd Crocus, *vulgo.*
13. Crocus *vernus latifolius, flore purpureo magno. C. B.* Broad-leav'd Spring Crocus, with a large purple Flower.
14. Crocus *vernus latifolius purpureus variegatus. C. B.* Broad-leav'd Spring Crocus, with a purple ſtriped Flower.
15. Crocus *vernus latifolius, flore cæruleo, lineis violaceis variegato. C. B.* Broad-leav'd Spring Crocus, with a blue Flower ſtriped with Violet.
16. Crocus *vernus, latifolius, albus, vel cinericeus. C. B.* Broad-leav'd Spring Crocus, with a white or aſh-colour'd Flower.
17. Crocus *vernus, latifolius, purpureo-violaceus. C. B.* The leſſer purple violet-colour'd Crocus, with broad Leaves.
18. Crocus *vernus latifolius parvus, flore extus pallido, cum lituris purpureis, intus cæruleſcente pallido. Boerh. Ind.* Broad-leav'd Spring Crocus, with a ſmall Flower of a pale Colour on the Outſide, with purple Stripes, and the Inſide of a pale blue Colour.
19. Crocus *vernus anguſtifolius, parvo flore. C.B.* Narrow-leav'd Spring Crocus, with a ſmall purple Flower.
20. Crocus *vernus, capillari folio. Cluſ. App.* Spring Crocus, with a capillaceous Leaf.

There are ſeveral other Varieties of the Spring *Crocus* to be found in the curious Gardens of Floriſts, which are ſeminal Productions; for there may be as great Variety of theſe Flowers raiſed from Seeds, as there is of *Hyacinths*, *Iris's*, &c. were we curious in ſaving and ſowing the Seeds of all the different Kinds. The Manner of ſowing theſe Seeds being exactly the ſame with the *Xiphium*, I ſhall refer the Reader to that Article for farther Inſtructions; but ſhall obſerve here, that the Seeds ſhould be ſown ſoon after they are ripe.

All theſe ſeveral Varieties of *Crocus's* are very hardy, and do increaſe exceedingly by their Roots, eſpecially if they are ſuffer'd to remain two or three Years unremoved; they will grow in almoſt any Soil or Situation, and are very great Ornaments to a Garden early in the Spring of the Year, before many other Flowers appear. They are commonly planted near the Edges of Borders on the Sides of Walks: In doing of which, you ſhould be careful to plant ſuch Sorts in the ſame Line as do flower at the ſame Time, and are of an equal Growth, otherwiſe the Lines will ſeem imperfect. Theſe Roots loſing their Fibres with their Leaves, may then be taken up and kept dry until the Beginning of *September*, obſerving to keep them from Vermin; for the Mice are very fond of them. When you plant theſe Roots, (after having drawn a Line upon the Border) make Holes with a Dibble about two Inches deep or more, according to the Lightneſs of the Soil, and two Inches Diſtance from each other, in which you muſt place the Roots with the Bud uppermoſt; then with a Rake fill up the Holes in ſuch a Manner as that the upper Part of the Root may be cover'd an Inch or more, being careful not to leave any of the Holes open; for this will intice the Mice to them, which, when once they have found them out, will deſtroy all your Roots, if they are not prevented.

In *January*, if the Weather is mild, the *Crocus* will appear above Ground; and in *February* their Flowers will appear, before the green Leaves are grown to any Length, ſo that the Flower ſeems at firſt to be naked; but ſoon after the Flowers decay, the green Leaves grow to be ſix or eight Inches long, which ſhould not be cut off until they decay, notwithſtanding they appear a little unſightly; for by cutting off the Leaves, the Roots will be ſo weaken'd as not to arrive at half their uſual Bigneſs, nor will their Flowers the ſucceeding Year be half ſo big: Their Seeds are commonly ripe about the latter End of *April*, or the Beginning of *May*, when the green Leaves begin to decay.

The ſecond Claſs, *or* Autumnal *Crocus's.*

1. Crocus *ſativus. C. B.* The true Saffron.
2. Crocus *Alpinus Autumnalis. C. B.* Autumnal *Crocus* of the *Alps.*
3. Crocus *juncifolius Autumnalis, flore magno purpuraſcente. Boerh. Ind.*

The Autumnal *Crocus's* are not ſo great Increaſers as are thoſe of the Spring, nor do they produce Seeds in our Climate, ſo that they are leſs common in the Gardens, except the true *Saffron*, which is propagated for Uſe in great Plenty in many Parts of *England*: theſe may be taken up every third Year, as was directed for the Spring *Crocus's*, but ſhould not be kept out of the Ground longer than the Beginning of *Auguſt*; for they commonly produce their Flowers in *September*, or the Beginning of *October*; ſo that if they remain too long out of the Ground, they will not produce their Flowers ſo ſtrong, nor in ſuch Plenty, as when they are planted early.

The Method of cultivating *Saffron* being ſomewhat curious, I thought it not improper to inſert in this Place an Abſtract of it, as it was preſented to the *Royal Society* by Dr. *James Douglas.*

As *Saffron* grows at preſent moſt plentifully in *Cambridgeſhire*, and has grown formerly in ſeveral other Counties of *England*, the Method of Culture does not, I believe, vary much in any of them, and therefore I judge it ſufficient to ſet down here the Obſervations which I employ'd proper Perſons, in different Seaſons, to make, in the Years 1723, 1724, 1725, and 1728, up and down all that large Tract of Ground that lies between *Saffron-Walden* and *Cambridge*, in a Circle about ten Miles diameter.

In that Country *Saffron* has been cultivated; and therefore it may reaſonably be expected, that the Inhabitants thereof are more thoroughly acquainted with it than they are any where elſe.

I ſhall begin with the Choice and Preparation of the Ground: The greateſt Part of the Tract already mention'd, is an open, level Country, with few Incloſures; and the Cuſtom there is, as in moſt other Places, to crop two Years, and let the Land be fallow the third. *Saffron* is always planted upon fallow Ground, and all other Things being alike, they prefer that which has borne Barley the Year before.

The *Saffron* Grounds are ſeldom above three Acres, or leſs than one; and in chuſing, the principal Thing they have Regard to, is, that they be well expoſed, the Soil not poor, nor a very ſtiff Clay, but a temperate dry Mould, ſuch as commonly lies upon Chalk, and is of a Hazel Colour; tho', if every thing elſe anſwers, the Colour of the Mould is pretty much neglected.

The Ground being made choice of, about *Lady-day* or the Beginning of *April*, it muſt be carefully plough'd, the Furrows being drawn much cloſer together, and deeper, if the Soil will allow it, than is done for any kind of Corn; and accordingly, the Charge is greater.

About five Weeks after, during any Time in the Month of *May*, they lay between twenty and thirty Loads of Dung upon each Acre, and having ſpread it with great Care, they plough it in as before: The ſhorteſt rotten Dung is the beſt; and the Farmers, who have the Conveniency of making it, ſpare no Pains to make it good, being ſure of a proportionable Price for it. About *Midſummer* they plough a third Time, and between every ſixteen Feet and a half, or Pole in Breadth, they leave a broad Furrow or Trench, which ſerves both as a Boundary to the ſeveral Parcels, when there are ſeveral Proprietors to one Incloſure, and to throw the Weeds in at the proper Seaſon.

To this Head likewiſe belongs the Fencing of the Grounds, becauſe moſt commonly, tho' not always, that is done before they plant. The Fences conſiſt of what they call dead Hedges, or Hurdles, to keep out not only Cattle of all Sorts, but eſpecially Hares, which would otherwiſe feed on the *Saffron* Leaves during the Winter.

About the Weather we need only obſerve, that the hotteſt Summers are certainly the beſt; and therewith, if there be gentle Showers from time to time, they can hardly miſs of a plentiful rich Crop, if the extreme Cold, Snow, or Rain of the foregoing Winter have not prejudiced the Heads.

The next general Part of the Culture of *Saffron* is, planting or ſetting the Roots: the only Inſtrument uſed for which, is a narrow Spade, commonly term'd a *Spit-ſhovel.*

The Time of planting is commonly in the Month of *July*, a little ſooner or later, according as the Weather anſwers. The Method is this: One Man with his Spit-ſhovel raiſes between three and four Inches of Earth, and throws it before him about ſix or more Inches; two Perſons, generally Women, following with Heads, place them in the fartheſt Edge of the Trench he makes, at three Inches Diſtance from each other, or thereabouts: As ſoon as the Digger or Spitter has gone once the Breadth of the Ridge, he begins again at the other Side, and digging, as before, covers the Roots laſt ſet, and makes the ſame Room for the Setters to place a new Row, at the ſame Diſtance from the firſt that they are from one another: thus they go on, till a whole Ridge, containing commonly one Rod, is planted; and the only Nicety in digging is, to leave ſome Part of the firſt *Stratum* of Earth untouch'd, to lie under the Roots; and, in ſetting, to place the Roots directly upon their Bottom.

What ſort of Roots are to be preferr'd, ſhall be ſhewn under the fourth Head: but it muſt be obſerv'd in this Place, that formerly, when Roots were very dear, they did not plant them ſo thick as they do now; and that they have always ſome Regard to the Size of the Roots, placing the largeſt at a greater Diſtance than the ſmall ones.

The Quantity of Roots planted in an Acre is generally about 16 Quarters, or 128 Buſhels, which, according to the Diſtances left between them, as before aſſign'd, and ſuppoſing all to be an Inch in Diameter one with another, ought to amount to 392,040 in Number.

From the Time that the Roots are planted, till about the Beginning of *September*, or ſometimes later, there is no more Labour about them; but as they then begin to ſpire, and are ready to ſhew themſelves above Ground, which is known by digging a few out of the Earth, the Ground muſt be carefully par'd with a ſharp Hough, and the Weeds, *&c.* rak'd into the Furrows, otherwiſe they would hinder the Growth of the Plants.

In ſome Time after appear the *Saffron-Flowers*; and this leads us to the third Branch of our preſent Method. The Flowers are gather'd as well before as after they are full blown; and the moſt proper Time for this is early in the Morning. The Owners of the *Saffron* get together a ſufficient Number of Hands, who place themſelves in different Parts of the Field, pull off the whole Flowers, and throw them Handful by Handful into a Baſket, and ſo continue till all the Flowers are gather'd, which happens commonly about Ten or Eleven o' Clock.

Having then carry'd home all they have got, they immediately ſpread them upon a large Table, and fall to picking out the *Filamenta Styli*, or Chives, and together with them a pretty long Portion of the *Stylus* itſelf, or String to which they are join'd; the reſt of the Flower they throw away as uſeleſs: the next Morning they return into the Field again, whether it be wet or dry Weather, and ſo on daily, even on *Sundays*, till the whole Crop be gathered.

The Chives being all pick'd out of the Flowers, the next Labour about them is to dry them on the Kiln. The Kiln is built upon a thick Plank (that it may be moved from Place to Place) ſupported by four ſhort Legs: The Outſide conſiſts of eight Pieces of Wood about three Inches thick, in Form of a quadrangular Frame, about 12 Inches ſquare at the Bottom on the Inſide, and 22 Inches at Top; which is likewiſe equal to the perpendicular Height of it. On the Foreſide is left a Hole about eight Inches ſquare, and four Inches above the Plank, thro' which the Fire is put in. Over all the reſt Laths are laid pretty thick, cloſe to one another, and nail'd to the Frame already mention'd, and then are plaiſter'd over on both Sides, as are alſo the Planks at Bottom very thick, to ſerve for a Hearth. Over the Mouth or wideſt Part goes a Hair-cloth, fix'd to the Sides of the Kiln, and likewiſe to two Rollers or moveable Pieces of Wood, which are turn'd by Wedges or Screws, in order to ſtretch the Cloth. Inſtead of the Hair-cloth, many People now uſe a Net-work, or Iron-wire, with which it is obſerv'd that the *Saffron* dries ſooner, and with a leſs Quantity of Fuel: but the Difficulty of preſerving the *Saffron* from burning, makes the Hair-cloth be preferr'd by the niceſt Judges in drying.

The Kiln is placed in a light Part of the Houſe; and they begin by laying five or ſix Sheets of white Paper on the Hair-cloth, upon which they ſpread the wet *Saffron* between two and three Inches thick; this they cover with other Sheets of Paper, and over theſe lay a coarſe Blanket five or ſix times doubled, or, inſtead thereof, a Canvas Pillow fill'd with Straw; and after the Fire has been lighted for ſome time, the whole is cover'd with a Board, having a large Weight upon it.

At firſt they give it a pretty ſtrong Heat, to make the Chives *ſweat*, (as their Expreſſion is) and in this, if they do not uſe a great deal of Care, they are in danger of ſcorching, and ſo of ſpoiling all that is on the Kiln.

When it has been thus dried about an Hour, they take off the Board, Blanket, and upper Papers, and take the *Saffron* off from that which lies next it, raiſing at the ſame time the Edges of the Cake, with a Knife: then laying on the Paper again, they ſlide in another Board between the Hair-cloth and under Papers, and turn both Papers and Saffron upſide-down; afterwards covering them (as above.)

This ſame Heat is continued for an Hour longer; then they look on the Cake again, free it from the Papers, and turn it: then they cover it, and lay on the Weight, as before. If nothing happens amiſs during theſe firſt two Hours, they reckon the Danger to be over; for they have nothing more to do, but to keep a gentle Fire, and to turn their Cakes every half Hour, till thoroughly dry: for the doing of which, as it ought, there are requir'd full 24 Hours.

In drying the larger plump Chives they uſe nothing more, but toward the latter End of the Crop, when theſe come to be ſmaller, they ſprinkle the Cake with a little Small-beer, to make it ſweat as it ought; and they begin now to think, that uſing two Linnen-cloths next the Cake, inſtead of the two innermoſt Papers, may be of ſome Advantage in drying: but this Practice is follow'd as yet but by few.

Their Fire may be made of any kind of Fuel; but that which ſmoaks the leaſt it beſt; and Charcoal, for that Reaſon, is preferr'd to any other.

What Quantity of *Saffron* a firſt Crop will produce, is very uncertain: ſometimes five or ſix Pounds of wet Chives are got from one Rood; ſometimes not above one or two; and ſometimes not enough to make it worth while to gather and dry it. But this is always to be obſerv'd, that about five Pounds of wet *Saffron* go to make one Pound of dry, for the firſt three Weeks of the Crop, and ſix Pound during the laſt Week: And now the Heads are planted very thick, two Pounds of dried *Saffron* may, at a Medium, be allow'd to an Acre for a firſt Crop, and 24 Pounds for the two remaining; the third being conſiderably larger than the ſecond.

In order to obtain theſe, there is only a Repetition to be made every Year of the Labour of Houghing, Gathering, Picking, and Drying, in the ſame Manner as before ſet down, without the Addition of any thing new; except that they let Cattle into the Fields, after the Leaves are decay'd, to feed upon the Weeds; or, perhaps, mow them for the ſame Uſe.

About the *Midſummer* after the third Crop is gather'd, the Roots muſt be all taken up and tranſplanted: the Management requiſite for which, is the fourth Thing to be treated of. To take up the *Saffron* Heads, or *break up the Ground*, (as the Term is) they ſometimes plow it, ſometimes uſe a forked kind of Hough, call'd a Pattock, and then the Ground is harrow'd once or twice over; during all which Time of Ploughing or Digging, and Harrowing, fifteen or more People will find Work enough to follow and gather the Heads as they are turn'd up.

They are next to be carried to the Houſe in Sacks, and there to be clean'd and raſed: this Labour conſiſts in cleaning the Roots thoroughly from Earth, and from the Remains of old Roots, old *Involucra*, and Excreſcencies; and thus they become fit to be planted in new Ground immediately, or to be kept for ſome Time without Danger of ſpoiling.

The Quantity of Roots taken up, in proportion to thoſe which were planted, is uncertain; but at a Medium, it may be ſaid, that allowing for all the Accidents which happen'd to them in the Ground, and in breaking up, from each Acre may be had 24 Quarters of clean Roots, all fit to be planted.

The Owners are ſure to chuſe for their own Uſe the largeſt, plumpeſt, and fatteſt Roots; but leaſt of all do they approve the longeſt pointed ones, which they call *Spicketi*, or *Spickards*; for very ſmall round or flat Roots are ſometimes obſerv'd to flower.

This is the whole Culture of *Saffron* in the Country abovementioned; and we have only now to conſider the Charges and Profits which may be ſuppoſed, one Year with another, to attend that Branch of Agriculture: and of theſe I have drawn up the following Computation for one Acre of Ground, according to the Price of Labour in this Country.

	l.	*s.*	*d.*
Rent for three Years	3	00	00
Ploughing for three Years	0	18	00
Dunging	3	12	00
Hedging	1	16	00
Spitting and ſetting the Heads	1	12	00
Weeding or paring the Ground	1	04	00
Gathering and picking the Flowers	6	10	00
Drying the Flowers	1	06	00
Inſtruments of Labour for three Years with the Kiln, about	0	10	00
Ploughing the Ground once, and Harrowing twice	0	12	00
Gathering the *Saffron* Heads	1	00	00
Raiſing the Heads	1	12	00
Total Charge	23	12	00

This Calculation is made upon Suppoſition, that an Acre of Ground yields 26 Pounds of neat *Saffron* in three Years, which I ſtated only as a mean Quantity between the greateſt and the leaſt, and therefore the Price of *Saffron* muſt be judg'd accordingly; which I think cannot be done better than by fixing it at 30 Shillings *per* Pound, ſince in very plentiful Years it is ſold at 20, and is ſometimes worth between three and four Pounds: at this Rate 26 Pounds of *Saffron* are worth 39 Pounds; and the neat Profits of an Acre of Ground producing *Saffron*, will in three Years amount to 15 Pounds 13 Shillings, or to about 5 Pounds 4 Shillings yearly.

This, I ſay, may be reckon'd the neat Profit of an Acre of *Saffron*, ſuppoſing that all the Labour were to be hir'd for ready Money: but as the Planter and Family do a conſiderable Part of the Work themſelves, ſome of this Expence is ſaved; that is, by planting *Saffron*, he may not only reaſonably expect clear about five Pounds yearly *per* Acre, but alſo to maintain himſelf and Family for ſome Part of each Year: and it is upon this Suppoſition only, that the Reſult of other Computations can be ſaid to have any tolerable Degree of Exactneſs; but the Calculations themſelves are undoubtedly very unaccurate.

I have ſaid nothing here concerning the Charge in Buying, or Profits in Selling the *Saffron-heads*, becauſe in many large Tracts of Ground theſe muſt at length balance one another, while the Quantity of Ground planted yearly continues the ſame, which has been pretty much the Caſe for ſeveral Years paſt.

Dr. *Patrick Blair*, deſigning to treat concerning the *Crocus*, in his VIth Decade of his *Pharmaco-Botanologia*, did, in the Year 1725. ſend to me the following Queries:

1. After what Manner the Species are propagated?
2. Whether the Tap-Root ſprings firſt, or the Bulb?
3. At what Seaſon the Leaves do ſpring forth?

To theſe Queries I ſent him the following Anſwer:

1. As to the Propagation of the Species.

This is only by the Roots or Off-ſets, which the old Roots produce in great Plenty; for I never ſaw any thing like a *Seed* or a *Seed-veſſel* produced, altho' I have let ſtand great Quantities of Flowers, purpoſely to try.

2. As to the Query, Whether the Tap-Root ſpring firſt, and the Bulb be afterwards form'd?

As ſoon as the Roots begin to ſhoot upwards, there are commonly two or three large *Tap-Roots* ſent forth from the Side of the old *Root*, which will run downright two Inches and a half, or more, into the Ground: at the Place where theſe *Bulbs* firſt come out from the *old one*, will be form'd a *Bulb*, ſometimes (tho' not always, as you will hear preſently); and this *Tap-Root* decays. The *Bulb* will increaſe in its Bigneſs, till at laſt it quite falls off, and is then left intire; which commonly happens in *April*, when the Green begins to decay: but many times theſe *tap* or *carroty Roots* never produce any *Bulbs*, but always retain the ſame Figure, and for ever after, I believe, are barren; for I planted a Parcel of theſe *carroty Roots* four Years ago in a little Bed, where they have ever ſince remain'd, but have not produced me one ſingle Flower, notwithſtanding they have produced a numerous Offſpring of the ſame *carroty Roots*.

And the People about *Saffron-Walden* are well appriz'd of this Barrenneſs, and therefore throw away all ſuch Roots when they make a new Plantation: but as this Change of the Root is not peculiar to the *Saffron* only, permit me to digreſs a little, to give you ſome Account of this Matter.

In the Pariſh of *Fulham* near *London*, the Gardeners uſed to drive a great Trade in the *Junquil*, or *Narciſſus juncifoliui, flore multiplici*, at which Place the greateſt Quantity of thoſe Roots was raiſed for Sale, as perhaps was in any Part of *England*, and turn'd to as great Account for the Maſter as any Crop they could employ their Ground in, till within theſe ſeven or eight Years; ſince which Time moſt of their Roots have turn'd *carroty*, and ſo proved barren, or have produced only ſingle Flowers; ſo that the Gardeners being hereby diſhearten'd, have thrown them out intirely, neglecting to cultivate them, ſatisfying themſelves with this Reaſon, that their Ground was tired with them.

But to return to the *Crocus*: Beſides thoſe *Roots* already mention'd, there will be three or four ſmall *Bulbs* form'd upon the upper Part of the *Root*, and ſome underneath, which from the firſt Appearance aſſume the round Shape of its Parent *Root*, and have no Tap-Root belonging to them; thoſe on the upper Part of the Root rarely emit ſo much as a Fibre, but receive their Nouriſhment immediately from the *old Root*; but thoſe on the under Side ſend forth many Fibres all around, by which they draw their Nouriſhment from the Ground; theſe being parted from the old Root much ſooner than the other, ſtand in need of fit Organs for receiving their Nouriſhment.

I have ſometimes taken up ſome, thro' the Middle of which hath been a Root of the *Gramen Caninum* or *Couch Graſs*, which ſome People have imagin'd had Strength enough to force its Way thro' the *Crocus Root*; but the Truth is, the *Root* of the *Graſs* cloſely adhering to the old *Root* of the *Crocus*, juſt at the Place where the young *Roots* were emitted, theſe young *Roots* being quick of Growth, incloſed the *Root* of the *Graſs*: and thus I have ſeen ſeveral *Roots* run thro' each other in the ſame Manner.

But beſides theſe Off-ſets mention'd, directly upon the upper Part of the *Root* is one large Root form'd, of equal Bigneſs with the old one; and this is the Time that the Root is *Radix Gemina*, as *Tournefort* calls it; for they are not ſo at any other Seaſon, and therefore I think it a very improper Appellation: for when the new *Roots* are perfectly form'd, the old ones with their *Coats* fall off and die, and leave the new *Roots* all ſingle: this has occaſion'd ſeveral People to doubt of what *Tournefort* has ſaid of the *Roots*, till I took up ſome Plants at that Seaſon, and with them the two *Roots* of equal Bigneſs, *i. e.* the *old one* at the Bottom, and the *new one* at the Top.

Dr. *Blair* alſo happening, in viewing a Root, to be ſurpriz'd with a different Appearance from what he had ſeen before, or heard of, ſent me another Letter.

The Manner of the Root was thus: From the upper Part of the *Bulb*, where it ſends forth all the Leaves within a common Tunicle, at the Exit there was an Appendix about an Inch and an half long, about the Groſneſs of a large Turkey or Gooſe Quill, cylindrical and blunt, without the leaſt *radical Fibre* by which it might receive the Nouriſhment; ſmooth or poliſh'd, and bluiſh in the Surface, conſiſting of ſeveral circular Lines, when cut tranſverſly; white, with an hard greeniſh Center like a *Carrot*, when it hath puſh'd forth the flowering Stem; not unlike the *Stolones* of ſome running *Root*, ſuch as the *Mints* below Ground, only the Extremity deſcended obliquely, inſtead of aſcending, to ſend forth *Leaves* to produce a new *Plant*: and, what is moſt remarkable, this did not happen to one or two Plants, but to the whole Bundle, which were above twenty diſtinct Sets, differing in nothing but *majus* and *minus*; the *Bulb* ſeem'd at the ſame time to be pined and emaciated, tho' it emitted large radical Fibres like thoſe of a *Leek*.

I having receiv'd this Account from him by Letter, ſent him the following Anſwer.

I receiv'd yours in Anſwer to my laſt, with the Figure of the Roots of ſome Sets of *Crocus Autumnalis* you have taken out of the Ground: I have found a Figure in *Dodonæus* which correſponds with it; and thoſe Roots are no new Thing with the *Saffron* Gardeners, who always throw them away when they make freſh Plantations.

Your Figure does not agree with my Tap-Roots, as you will ſee by the Figure taken as juſt from the Life as I could: In mine, you'll find the *Bulb* turn'd Side-ways, which I ſtill find to be conſtant in all the Roots I have examin'd, which have been a great many, and makes me ſuſpect theſe Tap-Roots are occaſion'd by the accidental Poſition of the *Roots* in planting, which may retard the aſcending Sap, the *flowering Stem* being thereby turn'd into a crooked Figure, and the Tap-Roots are full of longitudinal Veſſels of a conſiderable Dimenſion; ſo that the greater attracting Power of the Sap, being hereby diverted downwards, the *Flower-ſtem* may be quite deſtitute of proper Nouriſhment.

The Method you propoſe to remedy this Inconveniency will not do: for I have remov'd ſome of theſe Roots at the Seaſon when the Tap-Roots were forming, and this alone deſtroy'd them all; ſo that I am perſuaded, the cutting them off entirely will kill them.

The Method I uſed with the *Jonquils* was, to lay ſome Tiles juſt under the *Roots*, to prevent their running downwards: But this has not anſwer'd, nor do I think it poſſible wholly to recover them; for the Alteration is not only in the Root and Flower, but alſo in the Leaf and Blade, which before was fiſtulous: But after this Alteration in the Root, becomes a plain ſulcated Leaf, and if it ever bloſſoms after, the Flowers are large and ſingle, which before were ſmall and double: But the *Saffron*, after the Change of its Roots, produces a ſmall narrow Blade, ſeldom half the Length of thoſe in a natural State.

Upon this Dr. *Blair* form'd this Concluſion:

Theſe additional Obſervations plainly ſhew, that neither the *carroty Root*, nor the Baſtard Tap-Root, as I may call it, are merely accidental, or what may be call'd *Luſus Naturæ*, but certain Diſeaſes incident to ſuch Roots; for were they accidental, they would not have the ſame Appearances to different Perſons in different Soils and Climates, nor would ſo many taken up together have ſuch a Reſemblance to each other, as I have twice obſerv'd.

CROTOLARIA, [of Κρόταλον, *Gr.* a *Rattle*, becauſe it diſcharges its Seeds with a rattling; or becauſe the Infants of *Indians* make uſe of the Branches of this Plant furniſh'd with Pods inſtead of Rattles.]

The *Characters* are;

It hath ſingle Leaves, in which it differs from Reſt-harrow, *and the Pods are turgid, in which it differs from* Spaniſh Broom.

The *Species* are;

1. Crotolaria *Aſiatica, folio ſingulari verrucoſo, floribus cœruleis. H. L. Aſiatick* Crotolaria, with a ſingle warted Leaf, and blue Flowers.
2. Crotolaria *Aſiatica, folio ſingulari cordiformi, floribus luteis. H. L. Aſiatick* Crotolaria, with a Heart-ſhap'd Leaf, and yellow Flower.
3. Crotolaria *Africana, ſtyracis folio, flore cœruleo. Tourn. African* Crotolaria, with a Leaf of the Storax-tree, and a blue Flower.
4. Crotolaria *ſagittalis glabra, longioribus foliis, Americana. Pluk. Phyt. American* Crotolaria, with long, ſmooth, Spear-wort Leaves.
5. Crotolaria *Americana, caule alato, foliis piloſis, floribus in thyrſo luteis. Martyn. Decad.* 5. *American* Crotolaria, with a winged Stalk, hairy Leaves, and yellow Flowers growing in a Spike.
6. Crotolaria *ari folio ſagittato, flore luteo. Plum. Cat.* Crotolaria with a ſpear-ſhaped Arum Leaf, and a yellow Flower.
7. Crotolaria *ari folio ſagittato, flore purpuraſcente. Plum. Cat.* Crotolaria with a ſpear-ſhaped Arum Leaf, and a purpliſh Flower.
8. Crotalaria *fruteſcens hirſuta, flore luteo, ramulis alatis, foliis mucronatis. Houſt.* Shrubby hairy Crotolaria, with a yellow Flower, winged Branches, and pointed Leaves.

The firſt, ſecond, and fourth Roots are annual: The Seeds of theſe muſt be ſown on a Hot-bed early in the Spring; and when the Plants are come up, they muſt be tranſplanted into a freſh Hot-bed, and treated in the ſame Manner as is directed for *Amaranths*; (to which Article I refer the Reader, to avoid Repetition:) If theſe are brought forward early in the Year, they will produce their Flowers in *July*, and perfect their Seeds in *September*; but if they are late, and the Autumn ſhould prove bad, they will not live to ripen Seeds; therefore it is the better Way to place the Pots in a Bark-ſtove, which will bring them forward, and perfect their Seeds.

The third Sort will abide three or four Years, if preſerv'd in a warm Stove, and will produce Flowers and Seeds annually, by which it may be propagated. All theſe Varieties are very ornamental to curious Gardens of Plants.

The fifth, ſixth, and ſeventh Sorts are annual Plants, which ſhould be raiſed on a Hot-bed early in the Spring; for if they are not brought forward at that Seaſon, they ſeldom perfect their Seeds in this Country. Theſe Sorts are to be managed in the ſame Manner as thoſe above-mention'd.

The eighth Sort will grow to the Height of ſix or ſeven Feet, provided they are preſerved in a warm Stove, otherwiſe they will not live thro' the Winter. Theſe are propagated by Seeds which ſhould be ſown on a Hot-bed early in the Spring; and when the Plants are come up an Inch high, they ſhould be carefully tranſplanted into ſmall Pots filled with freſh Earth, and plunged into a Hot-bed of Tanners-bark, obſerving to ſhade them until they have taken Root; after which Time, they ſhould have Air and Water in proportion to the Warmth of the Seaſon. In this Bed they may remain until the Plants reach the Glaſſes, when they muſt be removed into the Bark-ſtove, obſerving to ſhift the Plants into larger Pots, as they ſhall require it.

CROWN IMPERIAL. *Vide* Corona Imperialis.

CRUCIATA, [is ſo call'd of *Crux*, *Lat.* a *Croſs*; becauſe the Leaves are diſpoſed in the Form of a Croſs; *i. e.* having four Leaves oppoſite each to the other] Croſs-wort.

The *Characters* are;

It hath ſoft Leaves like the Ladies Bed-ſtraw, *from which it differs in the Number of Leaves which are produced at every Joint, which in this are only four, diſpoſed in Form of a Croſs.*

The *Species* are;

1. Cruciata *hirſuta. C. B.* Rough or hairy Croſs-wort.
2. Cruciata *glabra. C. B.* Smooth Croſs-wort.
3. Cruciata *Alpina latifolia lævis. Tourn.* Broad ſmooth-leav'd Croſs-wort of the *Alps*.
4. Cruciata *Orientalis latifolia erecta glabra. T. Cor.* Upright and Oriental Croſs-wort, with broad ſmooth Leaves.

The firſt of theſe Plants is ſometimes uſed in Medicine: This is found wild in divers Parts of *England*, growing on dry ſandy Banks.

The other Sorts are preſerv'd in Botanic Gardens for the ſake of Variety, but there is no great Beauty in them. They may all of them be propagated eaſily by Perſons curious that Way; for they ſpread and increaſe by their creeping Roots, or their trailing Branches ſtriking Root as they lie upon the Ground. They love a light ſandy Soil.

CRUPINA BELGARUM. *Vide* Serratula.

CUCUBALUS, Berry-bearing Chickweed.

The *Characters* are;

The Flower conſiſts of five Leaves, which are bifid, and diſpoſed in a circular Order: The Pointal becomes a ſoft oval-ſhaped Berry, which is included in the Flower-cup, as in a Bladder, and containing many Kidney-ſhaped Seeds.

There is but one *Species* of this Plant, which is;

Cucubalus *Plinii. Lugd.* Berry-bearing Chickweed.

This Plant is of no great Uſe or Beauty, and is ſeldom preſerv'd in Gardens, except for Variety-ſake: It grows wild in many Parts of *Germany*, and hath alſo been found in the North Part of *England*. It is eaſily propagated by ſowing the Seeds, or planting the Roots, which will in a ſhort Time overſpread a large Spot of Ground, if ſuffer'd to remain; and it delights in a moiſt ſhady Place.

CUCULLATE PLANTS, [are ſo call'd, of *Cuculla*, Lat. a *Hood* or *Cowl*, ſuch as Monks wear, becauſe their Flowers reſemble it.]

CUCUMIS, [takes its Name of *Curvatura*, Lat. a *Bending*; becauſe the Stalks of this Plant are very crooked] The Cucumber.

The *Characters* are;

It hath a Flower conſiſting of one ſingle Leaf, which is Bell-ſhaped, and expanded towards the Top, and cut into many Segments, of which ſome are Male or Barren, having no Embryo, but only a large Style in the Middle, which is charg'd with the Farina; others are Female or Fruitful, being faſten'd to an Embryo, which is afterwards changed into a fleſhy Fruit, for the moſt part oblong, and turbinated, which is divided into three or four Cells incloſing many oblong Seeds.

The *Species* are;

1. Cucumis *ſativus vulgaris, maturo fructu ſubluteo. C. B.* The common Cucumber.
2. Cucumis *ſativus vulgaris, fructu albo. C. B.* The white Cucumber.

3. Cucumis *oblongus*. *Dod.* The long Turkey Cucumber.

The firſt of theſe Kinds is the moſt common in the *Engliſh* Gardens, of which there are two or three Varieties, differing in the Length or Roughneſs of the outer Skin of the Fruit: But theſe being only accidental Sportings of Nature, I ſhall paſs them over without making any Diſtinction of them.

The ſecond Sort, which is by far the better Fruit, (as being leſs Watery, and containing fewer Seeds) is the moſt common Kind cultivated in *Holland*; for I do not remember to have ſeen one of our green Sort in any of the Markets in *Holland*.

The third Sort is propagated in ſome curious Gardens, for the uncommon Length of its Fruit, and alſo its having leſs Water, and fewer Seeds: But it is not ſo fruitful as the common Kind, nor will it come up ſo eaſily.

The common Sort is cultivated in three different Seaſons: The firſt of which is on Hot-beds under Garden-Frames, for early Fruit: The ſecond is under Bell or Hand-Glaſſes, for the middle Crop: And the third is in the common Ground, for a late Crop, or to pickle.

I ſhall begin with giving Directions for raiſing *Cucumbers* early, which is what moſt Gentlemens Gardeners have an Emulation to exceed each other in; and ſome have been at the Pains and Expence to have ripe Fruit in every Month of the Year: Which is rather a Curioſity, than any real Advantage; for *Cucumbers* that are produced before *April* cannot be ſo wholſome as thoſe that are later: For before the Sun has Strength enough to warm the Beds thro' the Glaſſes in the Day-time, all the Force muſt proceed from the Fermentation of the Dung, which muſt conſequently occaſion a very conſiderable Steam, as alſo a great Quantity of Air will be thereby generated, which being pent up in the Hot-bed, ſoon becomes rancid, and the Steam of the Bed being by the Cold of the Night condenſed into large Drops of Water, which being abſorb'd or inſpir'd by the Plants, muſt certainly make the Fruit crude and unhealthy, eſpecially when the Nights are very long. This, together with the great Expence and Trouble of procuring them earlier, having almoſt got the better of People's Ambition, hath render'd it leſs practiſed than it hath been ſome Years ſince. I ſhall begin with giving plain Directions how to procure Plenty of good handſome Fruit in *April*.

Towards the latter End of *January* you muſt provide a Quantity of new Horſe-dung, with the Litter mix'd together, (in Proportion to the Number of Plants you intend to raiſe, which if for a private Family, two Loads will be full enough) this ſhould be thrown into a Heap, mixing a few Sea-coal Aſhes therewith; in about four or five Days after, the Dung will begin to heat, at which Time you may draw a little Part of the Heap on the Outſide flat, laying thereon a little good Earth, about two Inches thick; this you ſhould cover with a Bell-glaſs, laying a little dry Litter thereon; and in a Day or two after, when you perceive the Earth to be warm, you muſt put your Seeds therein, covering them about a quarter of an Inch, with the ſame Earth, then put the Glaſs on again: And alſo at Night, or in bad Weather, obſerve to cover the Glaſs with dry Litter or Mats, *&c.* and in three or four Days Time (if the Dung be in a good Temper of Heat) the Plants will appear above Ground; which when you firſt obſerve, you muſt immediately with the adjoining Heap of Dung make a Bed for one ſingle Light, being careful not to take the Dung away too cloſe to the Bell-glaſs, but obſerving to lay a little Dung round about it, as alſo to keep it cover'd, that the young Plants may not receive a Check thereby. This Hot-bed will require to be three Feet thick in Dung at leaſt, which, in the making, ſhould be carefully mix'd, and beat pretty cloſe with the Fork, to prevent the Heat from being too ſudden and violent: Then lay ſome fine freſh Earth upon the Dung about three Inches thick, levelling it very even, and put on the Frame, covering it over in the Night, or in bad Weather with a Mat, *&c.* as before, in order to excite a Heat in the Bed; and as ſoon as you perceive the Bed to be in a good kindly Temper of Heat, you ſhould prick your young Plants thereon, at about two Inches diſtance each Way, obſerving to put them into the Earth almoſt up to their Seed-leaves.

If the Bed is of a good Temper for Heat, your Plants will take Root in leſs than twenty-four Hours; after which Time you muſt be careful to let in a little Air, at ſuch Times when the Weather will permit, as alſo to turn the Glaſſes upſide downwards every Day to dry; for the Steam of the Bed condenſing on the Glaſſes, will fall down upon the Plants, and be very injurious to them; and therefore whenever the Weather is ſo bad as not to permit the Glaſſes to lie turn'd long, you ſhould at leaſt turn them once or twice a Day, and wipe off the Moiſture with a Woollen Cloth; but you muſt alſo be very careful how you let in too much cold Air, which is equally deſtructive to the tender Plants; therefore, to avoid this, it is a very good Method to faſten before the upper Side of the Frame, where the Air is ſuffer'd to enter the Bed, a Piece of coarſe Cloth, or a Mat, ſo that the Air which enters may paſs thro' that, which will render it leſs injurious to your Plants.

You muſt alſo be very cautious in giving Water to the Plants while young; and whenever this is done, it ſhould be ſparingly, and the Water ſhould be placed either into a Heap of Dung, or in ſome other Place, for ſome Time before it is uſed, ſo as to be nearly of a Temperature for Warmth with the incloſed Air of the Hot-bed; and as the Plants advance in Height, you ſhould have a little dry ſifted Earth always ready, to Earth up their Shanks, which will greatly ſtrengthen them: You muſt alſo be very careful ſo to keep up the Heat of the Bed; which if you ſhould find decline, you muſt lay a little freſh Litter round about the Sides of the Bed, and alſo keep the Glaſſes well cover'd in the Nights, or in bad Weather; but if, on the other Hand, your Bed ſhould prove too hot, you ſhould thruſt a large Stake into the Side of the Dung in two or three Places almoſt to the Middle of the Bed, which will make large Holes, thro' which the greateſt Part of the Steam will paſs off without aſcending to the Top of the Bed; and when you find it has anſwer'd your Purpoſe by ſlacking the Heat of your Bed, you muſt ſtop them up again with Dung.

Theſe Directions, if carefully attended to, will be ſufficient for raiſing the Plants in the firſt Bed: You muſt therefore, when you perceive the third or rough Leaf begin to appear, prepare another Heap of freſh Dung, which ſhould be mix'd with Aſhes, as was before directed: This ſhould be in Quantity according to the Number of Holes you intend to make: The common Allowance for ridging out the earlieſt Plants is, one Load to each Light or Hole, ſo that the Bed will be near three Feet thick in Dung; but for ſuch as are not ridg'd out till *March*, two Loads of Dung will be ſufficient for three Holes; for I could never obſerve any Advantage in making theſe Beds ſo thick with Dung as ſome People do: Their Crops are ſeldom better, if ſo good, as thoſe which are of a moderate Subſtance, nor are they forwarder, and the Fruit is rarely ſo fair, nor do the Vines continue ſo long in Health.

In making theſe Beds you muſt carefully mix the Dung, ſhaking it well with the Fork, ſo as not to leave any Clods of Dung unſeparated, as alſo to beat it down pretty cloſe, to prevent the Steam from riſing too haſtily; you muſt alſo be careful to lay it very even, and to beat or preſs down the Dung equally in every Part of the Bed, otherwiſe it will ſettle in Holes, which will be very hurtful: When you finiſh laying the Dung, you muſt make a Hole exactly in the Middle of each Light, about a Foot deep, and eight or nine Inches over; theſe Holes muſt be fill'd with light freſh Earth, which ſhould be ſcreen'd to take out all large Stones, Clods, *&c.* laying it up in a Hill, and in the Middle of each thruſt in a Stick about 18 Inches long, which ſhould ſtand as a Mark to find the exact Place where the Hole is; then Earth the Bed all over about three Inches thick, levelling it ſmooth, and afterwards ſet the Frame upon it, covering it with the Glaſſes.

In two or three Days Time your Bed will be in fit Order to receive your Plants; of which you may eaſily judge by pulling out one of the Sticks which was put in the Middle of the Holes, and feeling the lower Part of it, which will ſatiſfy you what Condition your Bed is in: Then you muſt ſtir up the Earth in the Middle of the Hole with your Hand, breaking all Clods, and removing all large Stones, making the Earth hollow in Form of a Baſon: Into each of theſe Holes you muſt plant four Plants; in doing of which, obſerve to make the Holes for the Plants a little ſlanting towards the Middle of the Baſon, eſpecially if your Plants are long-ſhank'd: This is intended to place the Roots of the Plants as far as poſſible from the Dung, to which if they approach too near, the lower Part of their Roots are ſubject to be burn'd off: Then ſettle the Earth gently to each Plant, and if the Earth is dry, it will be proper to give them a little Water, (which ſhould be warm'd to the Temper of the Bed, as was before directed); and if the Sun ſhould appear in the Middle of the Day, they ſhould be ſhaded therefrom with Mats until the Plants have taken Root, which will be in two or three Days; after which, you muſt let them enjoy as much of the Sun as poſſible, obſerving to turn the Lights in the Day-time to dry, as alſo to give a little Air whenever the Weather will permit.

You muſt alſo obſerve to keep the Glaſſes cover'd every Night, and in bad Weather; but be very careful not to keep them cover'd too cloſe, eſpecially while the Bed has a great Steam in it, which will cauſe a Damp to ſettle upon the Plants, which, for want of Air to keep the Fluid in Motion, will ſtagnate and rot them.

When your Plants are grown to be four or five Inches high, you muſt, with ſome ſlender forked Sticks, incline them toward the Earth, each one a ſeparate Way ; but this muſt be done gently at firſt, leſt by forcing them too much, you ſhould ſtrain or break the tender Veſſels of the Plants, which would be very hurtful to them : In this Manner you ſhould from Time to Time obſerve to peg down the Runners as they are produced, laying each in exact Order, ſo as not to interfere or croſs each other, nor ſhould you ever after remove them from their Places, or handle them too roughly, whereby the Leaves them ; be broken or diſplaced, which is alſo equally injurious to many but whenever you have Occaſion to weed the Bed between the Plants, do it with great Care, holding the Leaves aſide with one Hand, while with the other you pull out the Weeds.

In about a Month after they are ridg'd out, you may expect to ſee the Beginnings of Fruit, which very often are preceded by Male Flowers, which many People are ſo ignorant as to pull off, calling them falſe Bloſſoms ; but this I am fully convinced, by many Experiments, is wrong ; for theſe Flowers are of abſolute Service to promote the Welfare of the Fruit ; which, when theſe Male Flowers are intirely taken off, does very often fall away, and come to nothing : Nor ſhould the Vines be pruned, as is too often the Practice of unſkilful People, eſpecially when they are too luxuriant, which often happens when the Seeds were freſh, or of the laſt Year's ſaving, and the Plants in good Heart : If this ſhould happen to be the Caſe, it would be very proper to pull up one of the Plants before it hath run ſo far as to intangle with the others ; for it often happens, that two or three Plants are better than four or five, when they are vigorous ; for when the Frame is too much crowded with Vine, the Fruit is ſeldom good, nor in ſuch Plenty, as when there is a more moderate Quantity of Shoots ; for the Air being hereby excluded from the Fruit, they often ſpot and decay, or fall off very young.

You muſt alſo be very careful to cover the Glaſſes every Night when your Fruit begins to appear, as alſo to lay a little freſh Litter or Mowings of Graſs round the Sides of the Bed to add a freſh Heat thereto ; for if the Heat of the Bed be ſpent, and the Nights prove cold, the Fruit will fall away and come to nothing ; and when the Sun is extreme hot, in the middle of the Day, you muſt cover the Glaſſes with Mats to ſhade the Vines ; for altho' they delight in Heat, yet the direct Rays of the Sun, when it has great Force, are very injurious, by either ſcorching thoſe Leaves which are near the Glaſſes, or by cauſing too great a Perſpiration, whereby the extreme Part of the Shoots and the large Leaves are left deſtitute of Nouriſhment, and the Fruit will be at a Stand, and often turn yellow before it arrives at half its Growth.

At this Time, when your Vines are ſpread, ſo as to cover the Hot-bed, it will be of great Service, when you water them, to ſprinkle them all over gently ſo as not to hurt the Leaves ; but obſerve to do this not at a Time when the Sun is very hot, for hereby I have known a whole Bed of *Cucumbers* ſpoil'd, for the Water remaining upon the Surface of the Leaves in Drops, doth collect the Rays of the Sun as it were to a Focus, and ſo ſcorches the Leaves, that in one Day's-time they have, from a bright Green, become of the Colour of brown Paper.

Theſe Directions, with diligent Obſervation, will be ſufficient for the Management of this Crop of *Cucumbers* ; and Vines thus treated will continue to ſupply you with Fruit till *Midſummer*, by which Time the ſecond Crop will come to bear : The Sowing and Managing of which is what I ſhall next proceed to.

About the beginning of *March*, or a little later, according to the Earlineſs of the Seaſon, you muſt put in your Seeds, either under a Bell-glaſs, or in the Upper-ſide of your early Hot-bed ; and when the Plants are come up, they ſhould be prick'd upon another moderate Hot-bed, which ſhould be cover'd with Bell or Hand-glaſſes plac'd as cloſe as poſſible to each other ; the Plants ſhould alſo be prick'd at about two Inches Diſtance from each other, obſerving to water and ſhade them until they have taken Root, which will be in a very ſhort Time : You muſt alſo cover the Glaſſes with Mats every Night, or in very bad Weather ; but in the Day-time, when the Weather is hot, you muſt raiſe the Glaſſes with a Stone on the oppoſite Side from the Wind, to give Air to the Plants, which will greatly ſtrengthen them : You muſt alſo water them as you ſhall find they require it ; but this muſt be done ſparingly while the Plants are young.

The beginning of *April* the Plants will be ſtrong enough to ridge out ; you muſt therefore be provided with a Heap of new Dung, in Proportion to the Quantity of Holes you intend to plant, allowing one Load to ſix Holes : When your Dung is fit for Uſe, you muſt dig a Trench about two Feet four Inches wide (and in Length juſt as you pleaſe, or the Place will allow) ; and if the Soil be dry, it ſhould be ten Inches deep, but if wet, very little in the Ground, levelling the Earth in the Bottom ; then put in your Dung, obſerving to ſtir and mix every Part of it, as was directed for the firſt Hot-beds, laying it cloſe and even.

When this is done, you muſt make Holes about eight Inches over, and ſix Inches deep, juſt in the Middle of the Ridge, and three Feet and an half Diſtance from each other ; and if there be more than one Ridge, the Diſtance of thoſe ought to be eight Feet and an half from each other ; then fill the Holes with good light Earth, putting a Stick into the Middle of each for a Mark, and afterwards cover the Ridge over with Earth about four Inches thick, laying the Earth the ſame thickneſs round the Sides : When the Earth is levell'd ſmooth, you muſt ſet the Glaſſes on upon the Holes, leaving them cloſe down about twenty-four Hours, in which Time the Earth in the Holes will be warm'd ſufficiently to receive the Plants ; then with your Hand ſtir up the Earth in the Holes, making it hollow in Form of a Baſon ; into each of which you ſhould plant four Plants, obſerving to water and ſhade them until they have taken Root : After which Time you muſt be careful to give them a little Air by raiſing the Glaſſes on the oppoſite Side to the Wind in proportion to the Heat of the Weather, as alſo to water them as you ſhall ſee they require it ; but you muſt only raiſe the Glaſſes in the middle of the Day until the Plants do fill the Glaſſes ; at which Time you ſhould raiſe the Glaſſes with a forked Stick on the South-ſide in Height proportionable to the Growth of the Plants, that they may not be ſcorch'd by the Sun : This alſo will harden and prepare the Plants to endure the open Air ; but you ſhould not expoſe them too ſoon thereto, for it often happens that there are Morning Froſts in *May*, which are many Times deſtructive to theſe Plants when expos'd thereto ; it is therefore the ſureſt Method to preſerve them under the Glaſſes as long as they can be kept in without Prejudice to the Plants : And if the Glaſſes are rais'd with two Bricks on the Backſide, and the forked Stick on the other Side, they may be kept in a great while without Danger.

Towards the latter end of *May*, when the Weather appears ſettled and warm, you ſhould turn your Plants down gently out of the Glaſs ; but do not perform this in a very dry hot ſunny Day, but rather when there is a cloudy Sky, and an Appearance of Rain : You muſt in doing of this raiſe the Glaſſes either upon Bricks or forked Sticks, whereby they may ſtand ſecure at about four or five Inches high from the Ground, that the Plants may lie under them without bruiſing ; nor ſhould you take the Glaſſes quite away until the latter end of *June*, or the beginning of *July* ; for theſe will preſerve the Moiſture much longer to their Roots than if they were quite expos'd to the open Air : about three Weeks after you have turn'd the Plants out of the Glaſſes, they will have made a conſiderable Progreſs, eſpecially if the Weather has been favourable ; at which time you ſhould dig up the Spaces of Ground between the Ridges, laying it very even ; then lay out the Runners of the Vines in exact Order, and be careful in this Work not to diſturb the Vines too much, not to bruiſe or break the Leaves : this digging of the Ground will looſen it, and thereby render it eaſy for the Roots of the Plants to ſtrike into it, as alſo render the Surface of the Earth more agreeable to the Vines that run upon it : After this there will be no farther Care needful, but only to keep them clear from Weeds, and to water them as often as they ſhall require, which they will ſoon ſhew, by the hanging of their greater Leaves. The Ridges thus manag'd will continue to produce large Quantities of Fruit from *June* until the latter end of *Auguſt*, after which time the Coldneſs of the Seaſon renders them unwholſome, eſpecially if the *Autumn* proves wet.

From theſe Ridges People commonly preſerve their *Cucumbers* for Seed, by making Choice of two or three of the faireſt Fruit upon each Hole, never leaving above one upon a Plant, and that ſituated near the Root of it ; for if you leave more, they will weaken the Plants ſo much, that your other Fruit will be ſmall, and fewer in Number. Theſe ſhould remain upon the Vines until the end of *Auguſt*, that the Seeds may be perfectly ripe ; and when you gather them from the Vines, it will be proper to ſet the Fruit in a Row upright againſt an Hedge or Wall, where they may remain until the outer Cover begins to decay ; at which time you ſhould cut them open and ſcrape out the Seeds, together with the Pulp, into a Tub, which ſhould be afterwards cover'd with a Board, to prevent Filth from getting amongſt the Pulp. In this Tub it ſhould be ſuffer'd to remain eight or ten Days, obſerving to ſtir it well with a long Stick to the Bottom every Day, in order to rot the Pulp, that it may be eaſily ſeparated from the Seeds ; then pour ſome Water into the Tub, ſtirring it well about, which will raiſe the Scum to the Top, but the Seeds will ſettle to the Bottom, ſo that by two or three times pouring in Water, and afterwards ſtraining it off from the Seeds, they will be perfectly clear'd from the Pulp; then you ſhould ſpread the Seeds upon a Mat, which ſhould be expos'd to the open Air three or four Days until they are perfectly dry, when they may be put up in Bags, and hung up in a dry Place where Vermin cannot come to them, where they will keep good for ſeveral Years, but are generally preferr'd when three or four Years old, as being apt to produce leſs vigorous, but more fruitful Plants.

I ſhall in the next place proceed to give Directions for managing *Cucumbers* for the laſt Crop, or what are generally call'd *Picklers*.

The Seaſon for ſowing theſe is towards the latter end of *May*, when the Weather is ſettled: The Ground where theſe are commonly ſown, is between *Colliflowers*, in wide Rows, between which are allow'd four Feet and an half Space when the *Colliflowers* were planted. In theſe Rows you ſhould dig up ſquare Holes at about three Feet and an half Diſtance from each, breaking the Earth well with a Spade, and afterwards ſmoothing and hollowing it in the Form of a Baſon with your Hand; then put eight or nine Seeds into the middle of each Hole, covering them over with Earth about half an Inch thick; and if it ſhould be very dry Weather, it will be proper to water the Holes gently in a Day or two after the Seeds are ſown, in order to facilitate their Germination.

In five or ſix Days, if the Weather be good, your Plants will begin to thruſt their Heads above Ground; at which time you ſhould be very careful to keep off the Sparrows, who are very fond of the young tender Heads of theſe Plants, and if they are not prevented, will deſtroy your whole Crop: But as it is not above a Week that the Plants are in this Danger, ſo it will be no great Trouble to look after them during that Time; for when the Plants are come up, and have expanded their Seed-leaves, the Sparrows will not meddle with them.

You muſt alſo be careful to water them gently, as you ſhall find the Drought of the Seaſon doth require; and when you perceive the third or rough Leaf of the Plants begin to appear, you muſt pull out all the weakeſt Plants, leaving only five of the moſt promiſing and beſt ſituated in each Hole, ſtirring the Earth round about them with a ſmall Hough to deſtroy the Weeds, and raiſe the Earth about the Shanks of the Plants, putting a little Earth between them, preſſing it gently down with your Hand, that the Plants may be thereby ſeparated from each other to a greater Diſtance; then give them a little Water (if the Weather be dry) to ſettle the Earth about them, which you muſt afterwards repeat as often as you ſhall find it neceſſary, ſtill being careful to keep the Ground clear from Weeds.

When your *Colliflowers* are quite drawn off the Ground from between the *Cucumbers*, you muſt hough and clean the Ground, drawing the Earth up round each Hole in Form of a Baſon, the better to contain the Water when it is given them; and alſo lay out the Plants in exact Order as they are to run and extend, ſo that they may not interfere with each other: And if all the five Plants before left are in good Condition, you ſhould pull out one of the worſt of them, and throw it away; for four good Plants will be full enough to remain for good; then lay a little Earth between the Plants left, preſſing it down gently with your Hand, the better to ſpread them each way, giving them a little Water to ſettle the Earth about them, repeating it as often as the Seaſon ſhall require, and obſerving to keep the Ground clean from Weeds: The Plants thus manag'd, will begin to produce Fruit toward the latter end of *July*, when you may either gather them young for pickling, or ſuffer them to grow for large Fruit.

The Quantity of Holes neceſſary for a Family is about fifty or ſixty; for if you have fewer, they will not produce enough to pay for pickling, without keeping them too long in the Houſe, for you can't expect to gather more than two hundred at each Time from fifty Holes; but this may be done twice a Week during the whole Seaſon, which commonly laſts five Weeks; ſo that from fifty Holes you may reaſonably expect to gather about two thouſand in the Seaſon, which, if they are taken ſmall, will not be too many for a private Family, eſpecially conſidering, that if you have fewer Holes, the Quantity each Week produc'd will ſcarcely be worth the Trouble of pickling.

But leſt I ſhould be cenſur'd by thoſe who delight in having very early *Cucumbers*, for omitting what they call an eſſential Part of Gardening, I ſhall beg Leave here to ſubjoin a ſhort Account of a Method which I have us'd with very good Succeſs, to obtain *Cucumbers* very early; which is, After having rais'd my Plants in the Manner before directed, for early *Cucumbers*, until they have put forth their rough Leaves, I prepar'd ſome looſe wrought Baskets, about eight Inches Diameter, and five Inches deep, with two ſmall Handles to each; then I made a freſh Hot-bed of good Strength, which would hold a Frame of two Lights; on this I plac'd the Baſkets, which were almoſt full of good light Earth, as near to each other as poſſible, by which means this ſmall Bed would contain eighteen or twenty Baſkets; then I fill'd up the Spaces between the Baſkets with the ſame light Earth as was put into the Baſkets, putting the Frame and Glaſſes over the Bed, which in two Days was in a proper Temperature of Heat to receive the Plants; then I put five into each Baſket, obſerving to water and ſhade them until they had taken Root; afterwards managing them as was before directed for the firſt Crop of *Cucumbers*, obſerving when the Bed began to loſe its Heat, to lay a little freſh Dung round the Sides, which added a new Heat to the Bed. In this Frame I ſuffer'd them to remain until the Plants were laid down, and had run to the Sides of the Baſkets; then I prepar'd the Ridge, which I made of a good Subſtance in Dung, and after it had lain two or three Days to heat, I remov'd the Plants in the Baſkets, placing one into the Hole in the middle of each Light: Theſe Plants in a ſhort time after produc'd Fruit, which, by the good Temper of Heat in the Bed, grew ſo faſt, that in three Weeks after removing the Baſkets, I cut *Cucumbers*. There are ſeveral Advantages in this Management; firſt, you can keep the Baſkets in a ſmall Room for a conſiderable Time, whereby your Frames may be employ'd in other Uſes: And ſecondly, a leſs Quantity of Dung is requir'd in this Way: Thirdly, when the Plants are in Baſkets, if you find your Bed too hot, it is but raiſing up the Baſkets, and they are ſecure from any Danger; and when the violent Heat is over, they may be ſettled down again: And laſtly, by having your Plants ſo forward for Fruit when they are put into the Ridges, the Heat of the Bed continues to ſet and bring off the firſt Crop of Fruit; for want of which kindly Heat, the firſt Setting or Crop of Fruit which appears upon the Vines, either drops off, or is a long time growing to Maturity; therefore from theſe and many other Advantages attending this Method, I may with Safety pronounce it, the beſt yet known to procure *Cucumbers* in any of the Winter or Spring Months.

CUCUMIS AGRESTIS. *Vide* Elaterium.

CUCURBITA, [is ſo call'd, as tho' *Curvata*, Lat. *Bended*; becauſe this Plant always bends, unleſs it be ſupported] The Gourd.

The *Characters* are;

It hath a Flower conſiſting of one Leaf, which is of the expanded Bell-ſhape; for the moſt part ſo deeply cut, that it ſeems to conſiſt of five diſtinct Leaves: This, like the Cucumber, has Male and Female Flowers on the ſame Plant; the Fruit of ſome Species is long, of others round or Bottle-ſhap'd, and is commonly divided into ſix Cells, in which are contain'd many flat oblong Seeds, which have ſometimes a Border round them.

The *Species* are;

1. Cucurbita *longa, folio molli, flore albo. J. B.* The long Gourd, with a ſoft Leaf, and a white Flower.
2. Cucurbita *falcata figura, folio molli, flore albo. C. B.* The Sickle-ſhap'd Gourd, with a ſoft Leaf, and a white Flower.
3. Cucurbita *latior, folio molli, flore albo. J. B.* Flat Gourd, with a ſoft Leaf, and a white Flower, *commonly call'd* Squaſhes.
4. Cucurbita *lagenaria, flore albo, folio molli. C. B.* Bottle-ſhap'd Gourd, with a ſoft Leaf, and a white Flower.

There are ſeveral other Varieties of this Plant, which are annually brought from *America*, where are numberleſs Varieties of theſe, and of *Pumkins* and *Calabaſhes*.

They may be all propagated by ſowing their Seeds in *March* on a Hot-bed; and when the Plants come up, they ſhould be tranſplanted on another moderate Bed, where they ſhould have a great deal of Air to ſtrengthen them; and when they have got four or five Leaves, they ſhould be tranſplanted into Holes made upon an old Dunghil, or ſome ſuch Place, allowing them a great deal of Room to run; for ſome of the Sorts will ſpread to a great Diſtance: I have meaſur'd a ſingle Plant, which had run upwards of forty Feet from the Hole, and had produc'd a great Number of Side-Branches; ſo that if the Plant had been encourag'd, and all the Side-Branches permitted to remain, I dare ſay it would have fairly over-ſpread twenty Rods of Ground. Which, to ſome People, may ſeem like a Romance: yet I can affirm it to be Fact, But what is this to the Account printed in the *Tranſactions of the Royal Society*, which was communicated to them by *Paul Dudley*, Eſq; from *New-England*, wherein Mention is made of a ſingle Plant of this Kind, which, without any Culture, ſpread over a large Spot of Ground, and from which Plant were gather'd Two Hundred and Sixty Fruits, each, one with another, as big as an Half-Peck!

Theſe Fruits are by ſome People gather'd while young, and boil'd; afterwards ſtripping off the outer Cover, and buttering them, they eat them with Meat, and are by ſome People mightily eſteem'd; eſpecially the firſt Sort, which is counted by far the ſweeteſt: Of this Kind I have ſeen a ſingle Fruit upwards of ſix Feet long, which has ripen'd perfectly well. But this is not common with us; tho' I have heard of their being longer in other Countries: This Sort requires to be ſown early in the Spring, and brought forward under Bell or Hand-Glaſſes, otherwiſe they ſeldom arrive to half their Maturity.

Theſe Plants requiring ſo much Room to ſpread, and their Fruit being very little valu'd in *England*, hath occaſion'd their not being cultivated amongſt us; we have ſo many Plants, Roots, or Fruits, which are greatly preferable to thoſe for Kitchen Uſes: but in ſome Parts of *America*, where Proviſions are not in ſo great Plenty, or ſo great Variety, theſe Fruits may be very acceptable.

CUCURBITIFERA ARBOR; [ſo call'd, becauſe it bears a Fruit reſembling a *Gourd*, having a hard Rind when ripe, containing a ſoft moiſt Pulp incompaſſing the Seed.] The Calabaſh-Tree.

The *Characters* are;

It hath an anomalous Flower, conſiſting of one Leaf, which is ſhap'd like a Bottle, and cut into ſeveral Segments; from the Cup of the Flower ariſes the Piſtillum, *which becomes a large fleſhy Fruit, with a hard Shell, in which are contain'd many Heart-ſhap'd Seeds.*

There is but one *Species* of this Tree at preſent in *England*, which is,

Cucurbitifera Arbor *Americana. H. L.* The Calabaſh-Tree.

This Tree grows to a conſiderable Height in the warmer Parts of *America*, where it produces a very large Fruit; the outer Coat of which becomes very hard, and, as it were, of a woody Subſtance, and is of great Uſe to the Inhabitants for Bowls, Cups, and many other Purpoſes in Life: but whether the Inſide or Pulp of the Fruit is of any Uſe to them, I can't ſay.

This Tree being a Native of the warmer Countries, muſt, with us, be kept in a Stove, with *Guava's*, &c. which Stove ſhould be kept to the temperate Heat, as mark'd on Mr. *Fowler*'s *Thermometers*, with which Heat I find they ſucceed better than in a greater. This Tree requires frequent Waterings, and a light ſandy Soil, and in Summer muſt have a great Quantity of free Air; for if it be kept too cloſe in that Seaſon, the Leaves are apt to be infeſted by a great Number of Inſects; which greatly deface the Tree and retard its Growth. To remedy this, whenever you ſee them firſt begin to attack the Leaves, you muſt carefully waſh them off with a woollen Rag; and then expoſe the Plant (if in Summer-time) to the open Air, or ſet it in ſome cooler Place in Winter. This Plant may be propagated by planting Cuttings in any of the Summer Months, which ſhould be put into Pots fill'd with good freſh Earth, and plung'd into a moderate Bed of Tanners-bark, obſerving to water and ſhade them in the Heat of the Day until they have taken Root. The Seeds of this Tree, if brought over freſh in the Fruit, will grow, if ſown on a Hot-bed, and manag'd as was directed for the *Anana's*; to which I ſhall refer the Reader, to avoid Repetition.

CUIETE, The Calabaſh-tree.

The *Characters* are;

It hath a Flower conſiſting of one Leaf of an anomalous Figure, and divided at the Brim into ſeveral Parts; from whoſe Cup riſes the Pointal, fixed like a Nail in the hinder Part of the Flower; which afterward becomes a fleſhy Fruit, having a hard Shell, incloſing many heart-ſhaped Seeds.

The *Species* are;

1. **Cuiete** *foliis oblongis anguſtis, magno fructu ovato. Plum. Nov. Gen.* The Calabaſh-tree with narrow oblong Leaves, and a large oval Fruit.
2. **Cuiete** *latifolia, fructu putamine fragili. Plum. Nov. Gen.* The broad-leav'd Calabaſh-tree, with tender-ſhelled Fruit.
3. **Cuiete** *minima, fructu duro. Plum. Nov. Gen.* The leaſt Calabaſh-tree, with a hard Fruit.
4. **Cuiete** *anguſtifolia, fructu minori globoſo. Plum. Nov. Gen.* Narrow-leav'd Calabaſh-tree, with a leſſer globular Fruit.
5. **Cuiete** *anguſtifolia, fructu minori ovato. Plum. Nov. Gen.* Narrow-leav'd Calabaſh-tree, with a leſſer oval Fruit.

The firſt and ſecond Sorts riſe to the Height of twenty-five or thirty Feet in the *Weſt Indies*, where they grow naturally in Woods and the Savanna's. The Shells of this Fruit are uſed by Negroes for Cups to drink out of; as alſo for Inſtruments of Muſick, by making a Hole in the Shell, and clearing it of the Pulp and Seeds; then they put in ſmall Stones, or the hard Seeds of Trees, with which they make a Sort of Rattle.

Theſe Plants are all of them tender, ſo cannot be maintained in this Country, unleſs they are preſerved in warm Stoves. They are propagated by Seeds, which ſhould be obtained from the Countries where they naturally grow: for they never produce any Fruit in this Country. Theſe Seeds ſhould be ſown early in the Spring, in Pots filled with light freſh Earth, and plunged into a Hot-bed of Tanners-bark; the Earth in theſe Pots muſt be frequently refreſhed with Water; for if it be kept dry, the Seeds will not vegetate: in about five Weeks after the Seeds are ſown, the Plants will begin to appear; when they muſt be duly watered, and the Glaſſes of the Hot-bed ſhould be raiſed every Day, to admit freſh Air to the Plants, and let the Steam, which will ariſe from the Bed, paſs off: which is very injurious to young Plants, when it is pent amongſt them. When the Plants are about two Inches high, they ſhould be carefully tranſplanted, each into a ſeparate ſmall Pot, filled with rich light Earth, and plunged into the Hot-bed again, being careful to ſcreen them from the Sun until they have taken new Root, after which Time they muſt have freſh Air admitted to them in proportion to the Warmth of the Seaſon, and muſt be duly watered; for as they naturally grow on ſwampy Grounds, ſo they require a pretty large Share of Moiſture in warm Weather.

In Winter theſe Plants muſt be removed into the Stove, and plunged into the Bark-bed; for they do not thrive well, if they are placed on Boards in a dry Stove; becauſe the Fibres of their Roots, which are toward the Side and Bottom of the Pots, will dry, and retard the Growth of the Plants, if the Pots are not ſurrounded with Tan, which always retains ſome Moiſture, which keeps the Fibres of the Plants ductile, and thereby is greatly beneficial to them.

In Summer, theſe Plants may have a large Share of Air, by opening of the Glaſſes of the Stove; but they will not thrive, if they are taken out of the Stove, and placed in the open Air; ſo that they ſhould always be kept in the Bark-ſtove, obſerving to ſhift them into larger Pots, as the Plants advance in their Growth. With this Management, theſe Plants may be preſerved many Years, and brought to a large Size; when they will make a fine Appearance amongſt tender exotick Plants in the Stove, for they retain their Leaves throughout the Year.

CULMIFEROUS PLANTS [are ſo call'd of *Culmus*, Lat. *Straw* or *Haulm*] are ſuch as have a ſmooth, jointed Stalk, and uſually hollow, and at each Joint wrapp'd about with ſingle, narrow, ſharp-pointed Leaves; and their Seeds are contain'd in chaffy Huſks, as Wheat, Barley, *&c.*

CUMINOIDES; [of Κύμινον and εἶδος, Gr. *Form*; becauſe (by reaſon of its Likeneſs to it) many Authors have confounded it with *Cummin.*] Wild Cummin.

The *Characters* are;

It hath Leaves conſiſting of many Lobes like thoſe of Burnet; *the ſmall Flowers, which conſiſt of many Petals, are collected into a round Head; the Petals (or Flower-Leaves) are fringed; each of theſe Flowers are ſucceeded by a ſingle Seed.*

There is but one *Species* of this Plant, which is,

Cuminoides *vulgare. Tourn.* Common Wild Cummin.

This Plant is preſerved in curious Botanick Gardens, for the ſake of Variety: But it being of no great Beauty or Uſe, is very ſeldom cultivated in other Gardens. The Seeds of this Plant ſhould be ſown ſoon after ripe; for if kept until Spring, they ſeldom ſucceed ſo well. It loves a light dry Soil: and if the Seeds are permitted to ſcatter upon the Ground, they will come up again, and require no farther Culture.

CUMINUM, [Κύμινον, of κυεῖν, Gr. to *bring forth*; becauſe it is ſaid to be very efficacious againſt Barrenneſs.] Cummin.

The *Characters* are;

The Root is annual; the Leaves are like thoſe of Fennel; *the Seeds are ſmall, long, narrow, and crooked; two of which ſucceed each Flower, as in the other umbelliferous Plants.*

There is but one *Species* of this Plant at preſent known in *England*, which is,

CUMINUM. *Mor. Umb.* Cummin.

This Plant is propagated for Sale in the Iſland of *Malta*, where it is call'd *Cumino aigro*, i. e. *hot Cummin.* But *Aniſe*, which they alſo propagate in no leſs Quantity, they call *Cumino dolce*, i. e. *ſweet Cummin.* So that many of the old Botaniſts were miſtaken, when they made two Species of *Cummin*, viz. *acre* and *dulce*.

The Seeds of this Plant are us'd in Medicine, which are brought from the above-mention'd Place; for the Plant is too tender to be cultivated to any Advantage in *England*: I have ſown the Seeds ſeveral times in the *Phyſick-Garden*, which have come up very well, and grown to be four or five Inches high; but have conſtantly decay'd, without producing any good Seeds. If any Perſon is inclin'd to cultivate a little of this Plant for Curioſity, the beſt Method is, to ſow the Seeds early upon a very moderate Hot-bed; and when the Plants are come up pretty ſtrong, they may be tranſplanted into a light Soil, at about four or five Inches Diſtance, where they may probably produce good Seeds.

CURRANT-TREE. *Vide* Ribes.

CURURU. This is the *Indian* Name for this Plant, and we know of no *Engliſh* Name to it at preſent.

The *Characters* are;

It hath a roſe-ſhaped Flower, conſiſting of four or more Petals, which are placed in a circular Order, from whoſe many-leav'd Flower-cup ariſes the Pointal; which afterward becomes a pear-ſhaped triangular Fruit, divided into three Parts from the Top to the Bottom, containing three fleſhy Seeds, which are faſtened to the Seed-veſſel by a ſlender red Filament.

The *Species* are;

1. CURURU *ſcandens enneaphylla, fructu racemoſo rubro. Plum. Nov. Gen.* Climbing nine-leav'd Cururu, with red Fruit growing in a Bunch.
2. CURURU *ſcandens pentaphylla. Plum. Nov. Gen.* Climbing five-leav'd Cururu.
3. CURURU *ſcandens triphylla. Plum. Nov. Gen.* Climbing three-leav'd Cururu.

Theſe Plants grow plentifully in the Iſland of *Jamaica*, at *La Vera Cruz*, and ſeveral other Parts of *America*; where they climb up Trees, and ramble over Hedges, Buſhes, or whatever grows near them. The firſt, which is the largeſt Plant of Growth, will many times climb up five and twenty, or thirty Feet high; the other two ſeldom grow above ſixteen or eighteen Feet high.

Theſe Plants are preſerved in curious Botanick Gardens for the ſake of Variety, but there is no great Beauty in them. They may be propagated by ſowing of their Seeds on a Hot-bed early in the Spring, and when the Plants are come up, they ſhould be each tranſplanted into a ſmall Half-penny Pot, filled with light freſh Earth, and then plunged into a moderate Hot-bed of Tanners-bark, obſerving to ſhade them until they have taken Root; after which Time they ſhould have a large Share of freſh Air admitted to them in warm Weather, and muſt be frequently refreſhed with Water. When the Plants have filled theſe Pots with their Roots, they ſhould be ſhifted into others of a larger Size, and plunged into the Hot-bed again, treating them as before; in this Bed they may remain till Autumn (provided there is Room for them under the Glaſs without being preſſed); then they muſt be removed into the Bark-ſtove, and placed toward the Backſide of the Bed; where if they are ſupported by a Trellaſs, they will climb up to a great Height, and produce Flowers. In Winter theſe Plants ſhould have a temperate Heat, and muſt be often refreſhed with Water.

CUSPIDATED PLANTS [are ſo call'd, of *Cuſpis*, Lat. the *Point of a Spear*] are ſuch *Plants*, the Leaves of which are pointed like a Spear.

CUSTARD-APPLE. *Vide* Anona.

CYANUS, [Κύανος, Gr. ſo call'd on Account of its Blue or Azure Colour.] Bottle-Flower.

The *Characters* are;

It hath a ſquamoſe hairy Calyx; the Diſk of the Flower is almoſt plain; but the Outer Florets round the Border are large, tubulous, and deeply cut in; theſe Outer Florets are always barren; but the Inner Florets have a ſingle naked Seed ſucceeding each.

The *Species* are;

1. CYANUS *montanus latifolius, vel verbaſculum cyanoides. C. B.* The Greater broad-leav'd Blue-bottle, *commonly call'd* Globe-Flower.
2. CYANUS *anguſtiore folio & longiore, Belgicus. H. R. Par.* The Greater narrow-leav'd Blue-bottle, or Globe-Flower.
3. CYANUS *floridus odoratus Turcicus, ſive Orientalis major, flore purpureo. Park.* The purple ſweet Sultan, *vulgo.*
4. CYANUS *floridus odoratus Turcicus, ſive Orientalis major, flore albo. H. R. Par.* The white ſweet Sultan, *vulgo.*
5. CYANUS *floridus odoratus Turcicus, ſive Orientalis major, flore incarnato. H. L.* Sweet Sultan, with a pale Flower.
6. CYANUS *floridus odoratus Turcicus, ſive Orientalis major, flore luteo. H. L.* The yellow ſweet Sultan.
7. CYANUS *ſegetum, flore cœruleo. C. B.* Corn Blue-bottle.
8. CYANUS *ſegetum, flore albo. C. B.* Corn-bottle, with a white Flower.
9. CYANUS *ſegetum, flore variegato.* Corn-bottle, with a variable Flower.

The firſt and ſecond Species are abiding Plants, which increaſe greatly by their creeping Roots. The firſt is very common in moſt of the old Country Gardens, but is ſeldom preſerved in curious Flower-Gardens, becauſe it is ſo apt to overſpread whatever Plants grow near it: however, it may have a Place in large Borders under Trees, or in Wilderneſſes, where it will thrive very well: And altho' it is a Flower of little Beauty; yet, for its Variety, and long Continuance to flower, it deſerves to be propagated in very large Gardens. The ſecond is at preſent leſs common in *England*, being rarely to be found but in Botanick Gardens: Theſe are multiply'd by taking Off-ſets from the old Roots (which they furniſh in great Plenty) either in Spring or Autumn, and will grow in any Soil or Situation.

The third, fourth, fifth and ſixth Sorts are commonly ſown on a Hot-bed, and treated as the *Balſamine*, or *Marvel of Peru*: but theſe will flower full as well if they are ſown on a Border of good light Earth, in a warm Poſition, (except the ſixth Sort, which ſhould have a Hot-bed); and when the Plants come up, they may be prick'd out upon another Bed of good Earth ſix Inches apart each Way, where they may remain until they are ſtrong enough to be tranſplanted where they are to flower; which may be either in Pots or in Borders amongſt other Annuals: in doing of which, you muſt be careful not to ſhake the Earth from their Roots; and when they are planted, they ſhould be water'd and ſhaded until they have taken new Root. In *July* theſe Plants will begin to flower, and continue until the Froſt prevents them. But you ſhould obſerve to let the earlieſt Flowers remain for Seeds; for if the Autumn ſhould prove cold and wet, the late Flowers will not produce good Seeds, eſpecially the yellow Sort, which ſeldom perfects Seeds unleſs they are brought to flower very early.

Theſe Plants are annual, and rarely continue after perfecting their Seeds; yet in order to have them flower early in the Seaſon, you may ſow their Seeds the latter End of *July*, or the Beginning of *Auguſt*, that the Plants may have Strength before the cold Weather comes on, which being planted into warm Borders will endure the Cold very well, (provided they are not ſo forward as to run up to flower) and will flower early the next Summer; by which Method you may always be ſure to obtain good Seeds.

The Corn Bottles are alſo Annuals, which for the Diverſity of their Flowers were propagated in Gardens, but of late Years they are almoſt excluded; however, the variable Flowers are worthy of a Place in every good Garden. Theſe ſhould be ſown in Autumn, and may be tranſplanted into large Borders, where they will endure the Cold, and flower early the ſucceeding Summer, and will grow in almoſt any Soil or Situation.

CYCLAMEN; [Κυκλάμενος, of Κύκλος, Gr. a *Circle*, becauſe the Root of this Plant is orbicular: It is call'd *Sowbread*, becauſe the Root is round like a Loaf, and the Sows eat it.] Sowbread.

The *Characters* are;

It hath a thick, round, fleſhy Root; the Flowers ariſe ſingly upon Pedicles from the Root, which conſiſt of one Leaf, divided into five or ſix Segments, which are reflex'd almoſt to the Bottom, where they are divided; the Pointal of the Flower becomes a round membranaceous Fruit, which contains many roundiſh Seeds, which being committed to the Earth, become a Root.

The *Species* are;

1. Cyclamen *hederæ folio. C. B. flore purpureo.* Common autumnal Sowbread, with purple Flowers.
2. Cyclamen *hederæ folio, flore albo.* Autumnal Sowbread, with a white Flower.
3. Cyclamen *orbiculato folio, inferne purpuraſcente. C. B.* Round-leav'd Sowbread, with Leaves of a purpliſh Colour underneath.
4. Cyclamen *vernum, minus orbiculato folio inferne rubente, flore minore ruberrimo. Mor. Hiſt.* Leſſer Spring Sowbread, with roundiſh Leaves of a reddiſh Colour underneath, with ſmall deep red Flowers.
5. Cyclamen *hyeme & vere florens, folio anguloſo amplo, flore albo, baſi purpurea, Percum dictum. H. R. Par.* The *Perſian* Winter and Spring-flowering Sowbread, with large white Flowers, and a purple Bottom.
6. Cyclamen *hyeme & vere florens, folio anguloſo amplo, flore carneo, baſi purpurea. H. R. Par.* The *Perſian* Winter and Spring-flowering Sowbread, with a large fleſh-coloured Flower, and a purple Bottom.
7. Cyclamen *vernum album. C. B.* White Spring-flowering Sowbread.

There are ſeveral other Varieties in the curious Gardens abroad, but theſe here mentioned are what we have at preſent in *England*.

The firſt and ſecond Sorts are very common in the *Engliſh* Gardens, and are very hardy. Theſe are propagated by ſowing their Seeds ſoon after they are ripe, in Tubs of freſh ſandy Earth, in the Manner directed for *Xiphium*, to which I ſhall refer to avoid Repetition. In four or five Years Time they will begin to flower, but their Roots being then ſmall, will produce very few Flowers; and as their Roots yearly increaſe in Bulk, ſo will the Number of Flowers increaſe in proportion. I have ſeen a ſingle Root of this Plant above fourteen Inches Diameter, which hath produc'd upwards of an hundred Flowers in one Seaſon.

The beſt Seaſon for tranſplanting theſe Roots is in *June* or *July*, ſoon after the Seeds are perfected; but they ſhould not be kept long out of the Ground, for the Roots are diſpos'd to ſhoot out freſh Fibres with the firſt moiſt Weather after the Seeds are fall'n, and in about ſix Weeks do produce their Flowers, which appear upon ſingle Footſtalks before the Leaves are produc'd: After the Flowers are blown, the green Leaves appear, which continue all the Winter; and being of a ſtrong Green, varied with White, it makes an handſome Appearance during that Seaſon: The Pedicle of the Flower afterwards twiſts like a Screw, incloſing the Embryo of the Fruit, by which means it is cover'd by the green Leaves, whereby it is protected from the Froſt, &c. and about the Beginning of *June* the Seeds will be perfected.

The third Sort was formerly more common in *England* than at preſent. This muſt be treated in the ſame manner with the two former, and flowers in the ſame Seaſon.

The fourth and ſeventh Sorts are tenderer than the former, and muſt either be planted in Pots, and ſhelter'd under a Frame in Winter, or be plac'd in a warm dry Border. Theſe produce their Flowers very early in the Spring, if the Froſt doth not prevent them. The Seeds of theſe are ripe about the ſame Time with the former, and muſt be ſown and manag'd in the ſame manner; but the Boxes of Seeds or young Plants of theſe Kinds ſhould be ſhelter'd in Winter.

The fifth and ſixth Sorts are ſtill more impatient of Cold and Wet than any of the former. Theſe muſt conſtantly be preſerv'd in Pots fill'd with ſandy light Earth, and hous'd in Winter, but ſhould be plac'd near the Glaſſes, where they may enjoy as much free open Air as poſſible, when the Weather will permit; for if they are crowded under other Plants, and are kept too cloſe, they are very ſubject to mould and rot; nor ſhould they have much Water in Winter, which is alſo very injurious to them: But whenever they want Water, it ſhould be given them ſparingly. In Summer theſe Plants may be expos'd to the open Air, when their green Leaves will decay; at which Time you ſhould remove them to a Place where they may have the Morning Sun until eleven o' Clock; but during the Time that the Roots are deſtitute of Leaves they ſhould have very little Water given them, becauſe at that Seaſon they are not capable of diſcharging the Moiſture. This is alſo the proper Seaſon to tranſplant the Roots, or to freſh earth them; and as the Autumn comes on, that the Heat decreaſes, they may be remov'd into Places more expos'd to the Sun, where they may remain until *October* before they need be hous'd.

Toward *Chriſtmas*, if the Roots are in good Health, they will begin to flower, and continue producing freſh Flowers until *April*; from which if you intend to have any Seeds, you muſt let the Pots be plac'd ſo as to receive a great Share of freſh Air; for if their Flowers are drawn up in the Houſe, they ſeldom produce any Seeds. Theſe Seeds are ripe about *July*, when they ſhould be immediately ſown in Pots or Caſes of good light undung'd Earth, which ſhould be ſhelter'd in Winter under a Frame, and expos'd in Summer in the ſame Manner as is directed for the older Roots, obſerving to remove them into Pots at a wider Diſtance when they are two Years old, and ſo from Time to Time, as their Roots increaſe in Bulk, you muſt give them more Room; and in about four or five Years Time they will begin to flower, when you ſhould let each Root have a ſeparate Pot, which at firſt may be ſmall; but when the Roots are grown large, they muſt be put into bigger Pots.

CYDONIA; takes its Name of *Cydon*, an Iſland near *Leſbos*, or the famous Town of *Crete* of that Name.] The Quince-Tree.

The *Characters* are;

The Tree is of low Stature; the Branches are diffus'd and crooked; the Flower and Fruit is like that of the Pear-Tree; *but however cultivated, the Fruit is ſour and aſtringent, and is cover'd with a Kind of Down.*

The *Species* are;

1. Cydonia *fructu oblongo læviori. Tourn.* The Pear Quince, *vulgo.*
2. Cydonia *fructu breviore & rotundiore. Tourn.* The Apple Quince, *vulgo.*
3. Cydonia *latifolia Luſitanica. Tourn.* The broad-leav'd *Portugal* Quince.
4. Cydonia *fructu oblongo lævi dulci edulique. Tourn.* The Quince-Tree, with oblong ſmooth ſweet Fruit, which are eatable.
5. Cydonia *fructu oblongo minori lanuginoſo non eduli. Tourn.* Quince-Tree with leſſer oblong downy Fruit, which are not eatable.
6. Cydonia *anguſtifolia vulgaris. Tourn.* The common Quince-Tree, with narrow Leaves.

The firſt three Sorts are cultivated in moſt Nurſeries near *London*, but the *Portugal* Kind is moſt valu'd for the Goodneſs of its Fruit.

They are all eaſily propagated, either by Layers, Suckers or Cuttings, which muſt be planted in a moiſt Soil. Thoſe rais'd from Suckers are ſeldom ſo well rooted as thoſe which are obtain'd from Cuttings or Layers, and are ſubject to produce Suckers again in greater Plenty, which is not ſo proper for Fruit-bearing Trees. The Cuttings ſhould be planted early in the Spring, and in dry Weather muſt be often water'd to encourage their Rooting: The ſecond Year after they ſhould be remov'd into a Nurſery at three Feet Diſtance Row from Row, and one Foot aſunder in the Rows, where they muſt be manag'd as was directed for *Apples*: In two or three Years Time theſe Trees will be fit to tranſplant, where they are to remain for good; which ſhould be either by the Side of a Ditch, River, or in ſome other moiſt Place, where they will produce a greater Plenty, and much larger Fruit than in a dry Soil; tho' thoſe in the dry Soil will be better taſted, and earlier ripe. Theſe Trees require very little pruning; the chief Thing to be obſerv'd, is, to keep their Stems clear from Suckers, and cut off ſuch Branches as croſs each other; ſo likewiſe all upright luxuriant Shoots from the Middle of the Tree ſhould be taken intirely out, that the Head may not be too much crowded with Wood, which is of ill Conſequence to all Sorts of Fruit Trees.

Theſe are alſo in great Eſteem for Stocks to graft and bud *Pears* on, which for Summer and Autumn Fruits are a great Improvement to them, eſpecially thoſe deſign'd for Walls and Eſpaliers: For the Trees upon theſe Stocks do not ſhoot ſo vigorouſly as thoſe upon free Stocks, and ſo may be kept in leſs Compaſs, and are ſooner diſpoſed to bear Fruits: But Winter Fruits do not ſucceed ſo well upon theſe Stocks, their Fruit being very ſubject to crack, and are commonly ſtony. The beſt Stocks are thoſe which are raiſed from Cuttings.

The three laſt Sorts may be cultivated in the ſame Manner as the common Sorts, and are equally hardy; ſo that I ſhall not repeat it in this Place, but ſhall only obſerve, that it is the beſt Way to propagate them, either by Cuttings or Layers; for thoſe which are propagated from Suckers, will always continue to ſend out a great Number of Suckers from their Roots, which renders them very unſightly.

CYNOGLOSSUM; [κυνόγλωσσον, of κυνὸς, a *Dog*; and γλῶσσα, Gr. the *Tongue*, ſo call'd, becauſe the Leaves of this Plant reſemble a Dog's Tongue] Hounds-Tongue.

The *Characters* are;

The Cup of the Flower conſiſts of one Leaf, which is deeply cut into five Parts; the Flower conſiſts of one Leaf, is Funnel-ſhap'd, and cut into five Segments; the Pointal, which ariſes from the Bottom of the Flower, changes into a Fruit compos'd of four rough, and for the moſt part burry Cells, each containing a flat Seed affix'd to a pyramidal and quadrilateral Placenta.

The *Species* are;

1. CYNOGLOSSUM *majus vulgare. C. B.* Common great Hounds-Tongue.
2. CYNOGLOSSUM *majus vulgare, flore albo. C. B.* Common Hounds-Tongue, with a white Flower.
3. CYNOGLOSSUM *montanum maximum. Tourn.* The largeſt Mountain Hounds-Tongue.
4. CYNOGLOSSUM *ſemper-virens. C. B.* Ever-green Hounds-Tongue.
5. CYNOGLOSSUM *Creticum, argenteo anguſto folio. C. B.* Candia Hounds-Tongue, with narrow Silver-colour'd Leaves.
6. CYNOGLOSSUM *folio molli incano, flore cæruleo, ſtriis rubris variegato. Mor. Hiſt.* Soft-leav'd hoary Hounds-Tongue, with blue Flowers ſtrip'd with Red.
7. CYNOGLOSSUM *hirſutum vineale minus, floſculis minimis cæruleis. Mor. Hiſt.* The leſſer hairy Hounds-Tongue, with ſmall blue Flowers.

There are ſeveral other Varieties of this Plant which are cultivated in curious Botanick Gardens; but as they are Plants of little Beauty, and the firſt Sort only is that which is commonly us'd in Medicine, and this growing in great Plenty wild upon Dunghils, and in ſhady Lanes in divers Parts of *England*, they are therefore ſeldom preſerved in Gardens. They may be eaſily cultivated by any Perſon that is curious that Way, by ſowing the Seeds early in the Spring, or in Autumn ſoon after they are ripe, in almoſt any Soil or Situation, (except the *Candia* Sort, which muſt have a warm Poſition, and a dry Soil) where they will flower and ſeed in Plenty; and if the Seeds are permitted to ſcatter, will abundantly ſupply the Place with young Plants. As the Roots are often uſed, ſo the proper Seaſon to take them up is ſoon after the Leaves decay, before they ſhoot again; which is what ſhould be obſerv'd of all Roots either for Meat or Medicine, for then it is that they have the moſt Virtue.

CYPRESSUS; takes its Name either of κύω, to *bring forth*, as tho' opening its Branches on both Sides; or of *Cypariſſus*, a certain Infant whom the Poets feign to have been transform'd into a *Cypreſs-Tree*] The Cypreſs-Tree.

The *Characters* are;

The Leaves are ſquamoſe and flat; the Male Flowers, which are ſquamoſe, grow at remote Diſtances from the Fruit on the ſame Tree; the Fruit is of a ſpherical Form, and is compos'd of many Woody Tubercles, in which are contain'd hard angular Seeds.

The *Species* are;

1. CYPRESSUS *meta in faſtigium convoluta, quæ Fæmina Plinii. Tourn.* The common Cypreſs-Tree.
2. CYPRESSUS *ramas extra ſe ſpargens, quæ Mas Plinii. Tourn.* The Male ſpreading Cypreſs, *vulgo*.
3. CYPRESSUS *Virginiana, foliis Acaciæ deciduis. H. L.* The *Virginian* Cypreſs-Tree, with Leaves like the *Acacia*, which fall off in Winter.
4. CYPRESSUS *Luſitanica patula, fructu minori. Tourn.* Spreading *Portugal* Cypreſs, with a ſmaller Fruit.
5. CYPRESSUS *Americana, fructu minimo. American* Cypreſs, with the leaſt Fruit, commonly called *White Cedar* in *America*.

The firſt of theſe Trees is very common in moſt of the old Gardens in *England*, but at preſent is not ſo much in Requeſt as formerly; tho' it is not without its Advantages: nor ſhould it be intirely rejected, as many Perſons are of Opinion; for it ſerves to add to the Beauty of Wilderneſſes, or Clumps of Ever-greens. It was formerly planted in Borders of Pleaſure-Gardens, and kept ſhorn into a pyramidal or conick Form; and ſome People, believing them ſubject to be kill'd if they cut them, ty'd them up with Cords into a pyramidal Figure; which Form they are naturally diſpos'd to grow in: But this winding them about, prevented the Air from entering the inward Parts of the Branches; ſo that the Leaves decay'd and became unſightly, and greatly retarded their Growth. And ſo thoſe which are ſheer'd, if the Operation is not perform'd in the Spring, or early in the Summer, are very ſubject to be injured by ſharp Winds and cutting Froſts in Winter. Wherefore, upon the Whole, I think it much better to ſuffer them to grow wild as they are naturally diſpos'd, planting them only amongſt other Ever-green Trees, where, by the Darkneſs of their green Leaves, together with their waving Heads, they will greatly add to the Variety.

The ſecond Sort is by far the largeſt-growing Tree, and is the moſt common Timber in the *Levant*; this, if planted upon a warm ſandy or gravelly Soil, will proſper wonderfully; and tho' it is not quite ſo tonſile a Plant as the firſt Sort, yet greatly recompenſes for that Defect, by its vigorous Growth, and Strength in reſiſting all Weathers. This Tree is very proper to intermix with Ever-greens of a ſecond Size next to Pines and Firs, to form Clumps, in which Caſe it will keep pace with the Trees of the ſame Line, and be very handſome. Beſides, the Wood of this Tree is very valuable, when grown to a Size fit for Planks; which I am convinc'd it will do, in as ſhort a Space as Oaks; therefore, why ſhould not this be cultivated for that Purpoſe, ſince there are many Places in *England* where the Soil is of a ſandy or gravelly Nature, and ſeldom produces any Thing worth the Manuring? Now, in ſuch Places theſe Trees would thrive wonderfully, and greatly add to the Pleaſure of the Owner, while growing, and afterwards render as much Profit to his Succeſſors, as perhaps the beſt Plantation of Oaks; eſpecially ſhould the Timber prove as good here, as in the Iſlands of the *Archipelago*, which I ſee no Reaſon to doubt of: For we find it was ſo gainful a Commodity to the Iſland of *Candia*, that the Plantations were called *Dos Filiæ*; the Felling of one of them, being reckon'd a Daughter's Portion.

The Timber of this Tree is ſaid to reſiſt the Worm, Moth, and all Putrefaction, and is ſaid to laſt many hundred Years. The Doors of St. *Peter*'s Church at *Rome* were framed of this Material, which laſted from the Great *Conſtantine* to Pope *Eugenius* IVth's Time, which was Eleven Hundred Years, and were then ſound and intire, when the Pope would needs change them for Gates of Braſs. The Coffins were made of this Material, in which *Thucydides* tells us the *Athenians* us'd to bury their *Heroes*; and the *Mummy*-Cheſts brought with thoſe condited Bodies out of *Egypt*, are many of them of this Material.

This Tree is by many learned Authors recommended for the Improvement of the Air, and a Specifick for the Lungs, as ſending forth great Quantities of Aromatick and Balſamick Emiſſions; wherefore many of the ancient Phyſicians of the Eaſtern Countries us'd to ſend their Patients, who were troubled with weak Lungs, to the Iſland of *Candia*, which at that Time abounded with theſe Trees, where, from the Effects of the Air alone, very few fail'd of a perfect Cure.

The third Sort is a Native of *America*, where it grows in watery Places, and ariſes to a prodigious Height, and is of a wonderful Bulk: I have been inform'd, that there are Trees of this Kind in *America* which are upwards of Seventy Feet High, and ſeveral Fathoms in Circumference; which Trees grow conſtantly in the Water: Therefore they may probably be of ſingular Advantage to plant in ſuch ſwampy or wet Soils where few other Trees will grow, eſpecially of the reſinous Kind. That they are very hardy, in reſpect to Cold, is evident, from ſome few Trees of this Kind which were formerly planted in *England*, particularly one in the Gardens of *John Tradeſcant* at *South-Lambeth* near *Vaux-hall*, which is upwards of Thirty Feet high, and of a conſiderable Bulk; which, tho' in a common Yard at preſent, where no Care is taken of it, but, on the contrary, many Hooks are drove into the Trunk, to faſten Cords thereto for Drying of Cloaths, yet the Tree is in great Health and Vigour; but hath not produced any Fruit as yet; which may be occaſion'd for want of Moiſture: for we often ſee many Aquatick Plants will grow upon a drier Soil; but yet are ſeldom ſo productive of either Flowers or Fruits, as thoſe which remain growing in the Water.

Theſe Trees are all propagated from Seeds, which ſhould be ſown early in the Spring on a Bed of warm, dry, ſandy Earth, which muſt be levell'd very ſmooth; then ſow the Seeds thereon pretty thick, ſifting the ſame light Earth over them half an Inch thick. If the Weather ſhould prove very warm and dry, it will be proper to water the Bed, which muſt be done very carefully, obſerving not to waſh the Seeds out of the Ground. In about a Month's Time (if your Seeds are good) the young Plants will appear above-ground, which muſt be conſtantly kept clean from Weeds, and in very dry Weather ſhould be often refreſh'd with Water; but this ſhould be done with great Caution, leſt you beat theſe tender-rooted Plants out of the Ground.

In this Bed the young Plants may remain two Years, by which Time they will have Strength enough to be tranſplanted into a Nurſery: The beſt Seaſon for removing them is in the Beginning of *April*, when the drying Eaſterly Winds of *March* are over; and, if poſſible, chuſe a cloudy Day, when it is inclinable to Rain: And in taking them out of the Seed-bed, preſerve the Roots as intire as poſſible, and, if you can, a Ball of Earth to each Plant. The Soil in which theſe Trees ſhould be planted, (as I before ſaid) ſhould be, for the two firſt Sorts, a warm Sand or Gravel; which when you have prepar'd, by careful digging and cleanſing from all noxious Weeds, you muſt lay it level: Then draw the Lines where the Trees are to be planted at three Feet aſunder, and plant the Trees at eighteen Inches Diſtance in the Rows, obſerving to cloſe the Earth well to their Roots, as alſo to lay a little Mulch upon the Surface of the Ground about their Stems; and water them well, to ſettle the Earth to their Roots; which ſhould be repeated twice a Week, until the Plants have taken freſh Root.

Theſe Plants may remain in the Nurſery three or four Years, according to the Progreſs they make, or your Ground is ready where they are to be planted: But if you intend to let them remain longer, you ſhould take up every other Tree in the Rows, and tranſplant out; for otherwiſe their Roots will be matted together, ſo that it will render it difficult to tranſplant them, as alſo endanger the future Growth of the Trees. When they are planted out for good, (if they are deſign'd for Timber) they ſhould be planted about eighteen or twenty Feet Diſtance every Way, and be very careful in removing them, not to ſhake the Earth from their Roots; to prevent which, you ſhould open the Ground about each Tree, cutting off all long Roots: Then working under the Ball of Earth, cut the downright Roots off; and after having pared off all the Earth from the upper Part of the Ball, as alſo reduc'd the Bulk of it, ſo that its Weight may not be too great for the Fibres to ſupport, they may be carried upon a Hand-Barrow by two Perſons to the Place where they are to be planted: but if they are to be carry'd to a very diſtant Place, they ſhould either be put into Baſkets, or their Roots cloſely matted up. When they are planted, you muſt ſettle the Earth cloſe to their Roots, (as before) laying a little Mulch upon the Surface of the Ground about their Stems, to prevent the Sun and Wind from entering the Earth to dry their Fibres; and water them well, to ſettle the Ground to their Roots; which muſt alſo be repeated (if the Weather be dry) until they have taken Root: after which Time they will require little more Care than to keep them clear from Weeds.

The firſt, which is the moſt common Sort in *England*, ſeldom produces good Seeds in this Country; it is therefore the beſt Way to have the Cones brought over intire from the South Parts of *France* or *Italy*, where they ripen perfectly well, and take the Seeds out juſt before you ſow them; for they will keep much better in the Cones, than if they are taken out: The Method to get the Seeds out, is to expoſe the Cones to a gentle Heat, which will cauſe them to open, and eaſily emit their Seeds.

The ſecond Sort produces very good Seeds in *England*; ſo that we may hope to be ſupply'd with Seeds in Plenty, in a few Years, from Trees of our own Growth: And as this is the more valuable Tree, ſo it will be no ſmall Advantage to our Plantations of Timber to introduce it amongſt them, eſpecially thoſe of Ever-green Trees.

The *Virginian* Kind may alſo be propagated in as great Plenty; for the Cones of this may be eaſily procur'd from *Carolina* or *Virginia*, in both which Places they grow in great Abundance; and the Seeds will riſe as eaſily as any of the other Sorts, and are equally as hardy; Theſe have been formerly kept in Pots and hous'd in Winter; with which Management they have not ſucceeded ſo well, as they have done in *England*, ſince People have planted them into the full Ground; and where they have had a moiſt Soil, I have obſerv'd them to thrive beſt: Which is ſince confirm'd by Mr. *Cateſby*, in his *Natural Hiſtory of* Carolina, where he ſays, that this Tree grows in Places where the Water commonly covers the Surface of the Ground three or four Feet; ſo that it may be a very great Improvement to our boggy Soils. This Tree caſting its Leaves in Winter, does not ſo well ſuit with Plantations of Ever-greens at that Seaſon; tho' in Summer, when there is the greateſt Pleaſure in walking among Plantations of Trees, it hath ſo much the Appearance of an Ever-green, as to paſs for ſuch, and therefore may be of Service to compleat Plantations, or Viſta's of *Cypreſs-Trees*, where it may ſo happen, that a low marſhy Spot of Ground may intervene.

The fourth Sort of theſe Trees is rarely to be ſeen in the *Engliſh* Gardens at preſent, nor is it ſo well worth Cultivating as any of the other Kinds, it being of humbler Growth, and of a leſs regular Figure. This may be propagated by Seeds in the ſame Manner as the common Sort, and is equally hardy; ſo that whoever hath an Inclination to cultivate this Tree, ſhould procure the Cones from *Liſbon*, near which Place it grows very common.

The fifth Sort is a Native of *North America*, where it grows to a conſiderable Height, and affords a uſeful Timber to the Inhabitants for many Purpoſes. This Sort is extremely worth cultivating in *England*; for as it grows in a much colder Country, ſo there is no Danger of its thriving well in the open Air in *England*; and being an Ever-green of regular Growth, ſo will add to the Variety in Wilderneſs Quarters, or other Plantations of Ever-green Trees.

This Sort is propagated by Seeds, which ſhould be ſown in the Spring, in Boxes or Tubs filled with light freſh Earth, and placed where they may enjoy the Morning Sun till eleven or twelve o' Clock; in dry Weather they ſhould be duly watered, and conſtantly kept clear from Weeds: In this Situation they may remain till *Michaelmas*, when they ſhould be removed to a warmer Place; for the Plants will not appear till the following Spring, ſo that it will be proper to place the Boxes or Tubs near a South Wall, Pale, or Hedge, during the Winter Seaſon, leſt by being too much ſhaded, the Wet of the Winter Seaſon ſhould rot the Seeds. In the Spring following, if theſe Tubs or Boxes are placed on a moderate Hot-bed, it will bring up the Plants very ſoon, and greatly forward their Growth; but as the Spring advances, ſo they ſhould be inured to bear the open Air by degrees; and in *May* they muſt be taken out of the Hot-bed, and placed in a ſheltered Situation, where they may enjoy the Morning Sun, being careful to keep them clear from Weeds, as alſo to water them duly in dry Weather. The following Winter it will be proper to remove the Tubs near a South Wall or Pale; for the Plants being very young, are ſomewhat tenderer than they will be afterward. Toward the latter End of *March*, or the Beginning of *April*, juſt before the Plants begin to ſhoot, they ſhould be carefully taken up out of the Boxes; and having prepared a Bed or two (according to the Quantity of Plants raiſed) of freſh Earth in a warm Situation, the Plants ſhould be planted therein in Rows about eighteen Inches aſunder, and about a Foot Diſtance Plant from Plant in the Rows: This Work ſhould be done in cloudy Weather, or when there is Rain; for in dry Weather, when Eaſterly Winds commonly blow at this Seaſon, it will be very dangerous to tranſplant theſe Plants; ſo that it had better be deferr'd a Fortnight longer, till there is an Alteration of Weather, than hazard the Plants. When the Plants are planted, they ſhould be watered to ſettle the Earth to their Roots; and then the Surface of the Ground ſhould be covered with Mulch, to prevent the Sun and Wind from penetrating to the Roots of the Plants; for nothing is more injurious to theſe Plants, than to have their Fibres dried when they are tranſplanted; therefore the Plants ſhould not be taken out of the Tubs, till you are ready to place them in the Ground; for they will not bear to lie out of the Ground any Time without great Danger.

Theſe Plants may remain in the Beds, where they are firſt tranſplanted, three or four Years; during which Time the Ground muſt be conſtantly kept clear from Weeds; and every Spring the Ground muſt be carefully dug between the Plants, in doing of which great Care ſhould be had, not to diſturb their Roots, nor to lay them bare, leſt the Wind and Sun ſhould injure them. When the Plants are about two Feet and a half, or three Feet high, they ſhould be tranſplanted where they are to remain: The Time for this Work is in *April*, in moiſt cloudy Weather. In taking of the Plants up, there ſhould be as much Earth preſerved to their Roots as poſſible; and if they are to be carried to any Diſtance, it will be proper to put them in Baſkets, to prevent the Earth from falling from them; for if it ſhould, there will be great Hazard of their growing: When they are planted, they muſt be well watered to ſettle the Earth to their Roots; and ſome Mulch ſhould be laid upon the Ground about their Roots, to prevent the Wind and Sun from drying of them; and if the Seaſon ſhould prove dry, it will be proper to water them once or twice a Week until they are thoroughly rooted; after which Time they will require no other Culture, but to keep them clear from Weeds, and dig the Ground about them every Spring; with this Management the Plants will make great Progreſs, and in a few Years will be out of any Danger.

This Sort of *Cypreſs* will grow as large in this Country, as the common Kind; ſo will be very proper to intermix with them, either in Wilderneſſes, or in any other Plantations of theſe Trees, which will make an agreeable Diverſity; and the Wood of theſe Trees may in Time become uſeful for many Purpoſes.

But ſuppoſing the Timber of theſe Trees were of no Uſe, yet are they ſo very ornamental to Gardens, that no large Garden can be complete without many of theſe Trees; and it is to theſe Trees that the *Italian* Villa's owe a great Share of their Beauty: for there is no Tree ſo proper to place near Buildings: the pyramidal upright Growth of their Branches afford a pictureſque Appearance, and do not obſtruct the View of the Building; and the Dark-green of their Leaves make a fine Contraſt with the White of their Building. So that, where-ever there are Temples or other Buildings erected in Gardens, there is no Sort of Tree ſo proper to place near them as theſe. In all the Landſkips of *Italian* Villa's, we ſee many Cypreſs Trees repreſented, which have a very agreeable Effect in the Picture; and the Trees, when rightly diſpoſed in a Garden, afford a no leſs agreeable Proſpect.

CYSTICAPNOS: [of κύςις, a *Bladder*, and καπνὸς, *i. e.* Fumitory, q. d. the Bladder Fumitory] *African* Bladder Fumitory.

The *Characters* are;

It hath an annual fibroſe Root; the Leaves, Branches, and Flowers, have the Appearance of Climbing Fumitory; the Fruit is an oval Bladder pierc'd thro' by an Axis, to which are faſten'd round Seeds on every Side, incloſ'd again with one common Veſicle, which is expanded about the Axis.

There is but one *Species* of this Plant at preſent known, which is;

Cysticapnos *Africana ſcandens. Boerh. Ind. African* Climbing Bladder Fumitory.

This Plant is annual; the Seeds of which may be ſown on a warm Border, where it is to remain, for it doth not care to be remov'd: It flowers in *July*, and the Seeds are perfected in *Auguſt* or *September*. It is a Plant of no great Beauty, but is preſerv'd in curious Botanick Gardens for the Sake of Variety.

CYTISO-GENISTA; [It is ſo call'd, becauſe it reſembles both the Plants *Cytiſus* and *Geniſta*] Common (or Green) Broom.

The *Characters* are;

It hath Papilionaceous (or Butterfly) Flowers; which are ſucceeded by compreſs'd Pods, in which are contain'd many Kidney-ſhap'd Seeds; the Branches of the Tree are flexible, and have ſometimes ſingle, and other times three Leaves join'd together.

There is but one *Species* of this Plant, which is,

Cytiso-genista *ſcoparia vulgaris, flore luteo. Tourn.* Common Broom.

This Shrub is rarely preſerv'd in Gardens, but grows wild upon barren dry Heaths in divers Parts of *England*, though, for Variety ſake, it may have a Place amongſt flowering Shrubs of a middle Growth in ſmaller Wilderneſs Quarters, where it will appear very well. This may be propagated by ſowing the Seeds in the Spring, or in Autumn ſoon after ripe; and when the Plants are one Year old, they ſhould be tranſplanted into a Nurſery, in order to prevent their making downright Roots, which this Plant is very ſubject to; and when they have remain'd two Years in the Nurſery, they will be fit to tranſplant into the Places where they are deſign'd to ſtand for good. The beſt Seaſon for tranſplanting theſe Shrubs is in the Beginning of *April*, when the drying Winds are over, and, if poſſible, chuſe a moiſt cloudy Day for this Work: After they are planted, the Earth ſhould be cloſ'd to their Roots, and a little Mulch laid thereon; then give them a good Watering, to ſettle the Earth to their Roots, and if the Seaſon ſhould prove dry, it ſhould be repeated twice a Week until they have taken freſh Roots, after which they will require very little Care.

This Plant is ſometimes us'd in Medicine.

CYTISUS; [This Plant takes its Name from *Cytiſus*, an Iſland where it grew in great Plenty] Baſe Tree Trefoil.

The *Characters* are;

It hath Papilionaceous (or Pea-bloom) Flowers, which are ſucceeded by compreſs'd Pods, in which are contain'd ſeveral Kidney-ſhap'd Seeds; to which may be added, the Leaves are for the moſt part roundiſh, and ſomewhat like thoſe of the Nettle-Tree.

The *Species* are;

1. Cytisus *Alpinus latifolius, flore racemoſo pendulo. Tourn.* The broad-leav'd Laburnum or Bean-Trefoil.

2. Cytisus *Alpinus anguſtifolius, flore racemoſo pendulo longiori. Tourn.* The narrow-leav'd Laburnum or Bean-Trefoil, with long pendulous Flowers.

3. Cytisus *Alpinus, flore racemoſo pendulo breviori. Tourn.* Broad-leav'd Laburnum or Bean-Trefoil, with very ſhort pendulous Flowers.

4. Cytisus *glaber nigricans. C. B.* The Black Baſe-tree Trefoil.

5. Cytisus *Canarienſis ſempervirens & incanus. Hort. Amſt.* Hoary Ever-green Canary Tree Trefoil.

6. Cytisus *glabris foliis ſubrotundis, pediculis breviſſimis. C. B. P.* Round-leav'd ſmooth Baſe-tree Trefoil, with ſhort Footſtalks. This is commonly ſold by the Nurſery Gardeners, under the Title of *Cytiſus ſecundus Cluſii.*

7. Cytisus *hirſutus. J. B.* Hairy Baſe-tree Ttrefoil.

8. Cytisus *ſpinoſus. H. L.* Prickly Baſe-tree Trefoil.

9. Cytisus *Monſpeluſanus, medicæ folio, ſiliquis denſe congeſtis & villoſis. Tourn.* Baſe-tree Trefoil of *Montpelier*, with medic Leaves, and hairy Pods, growing in Bunches.

10. Cytisus *incanus, ſiliquâ longiore. C. B. P.* Hoary Baſe-tree Trefoil, with a longer Pod.

11. Cytisus *hirſutus, flore luteo purpuraſcente. C. B. P.* Hairy Baſe-tree Trefoil, with a purpliſh yellow Flower.

12. Cytisus *glaber viridis. C. B. P.* Smooth green Baſe-tree Trefoil.

13. Cytisus *foliis incanis anguſtis, quaſi complicatis. C. B. P.* Baſe-tree Trefoil, with narrow hoary Leaves.

14. Cytisus *humilis argenteus anguſtifolius. Tourn.* Silvery-dwarf Baſe-tree Trefoil, with narrow Leaves.

15. Cytisus *glutinoſus, omnium minimus. Tourn.* The leaſt clammy Baſe-tree Trefoil.

16. Cytisus *argenteus linifolius, inſularum Stæchadum. Tourn.* Silvery Flax-leav'd Baſe-tree Trefoil, of the *Stechades Iſlands.*

17. Cytisus *Hiſpanicus procerior, anagyridis folio, floribus glomeratis. Tourn.* Taller *Spaniſh* Baſe-tree Trefoil, with an anagyris Leaf, and glomerated Flowers.

18. Cytisus *Hiſpanicus humilior, floribus glomeratis. Tourn.* Lower *Spaniſh* Baſe-tree Trefoil, with glomerated Flowers.

19. Cytisus *Luſitanicus, medicæ foliis, floribus in foliorum alis. Tourn. Portugal* Baſe-tree Trefoil, with a medic Leaf, and the Flowers growing at the Wings of the Leaves.

20. Cytisus *Luſitanicus, foliis minimis argenteis, parvo flore albo. Tourn. Portugal* Baſe-tree Trefoil, with the leaſt Silvery-leaves, and a ſmall white Flower.

21. Cytisus *Luſitanicus, foliis exiguis, magno flore, ſiliquis latis & tomentoſis. Tourn. Portugal* Baſe-tree Trefoil, with ſmall Leaves, a large Flower, and broad woolly Pods.

22. Cytisus *ſpinoſus, ſiliquâ villoſa incanâ. Tourn. Cor.* Prickly Baſe-tree Trefoil, with white hairy Pods.

23. Cytisus *ſpinoſus Creticus, ſiliquâ villis denſiſſimis longiſſimis & incanis obductâ. Tourn. Cor.* Prickly Baſe-tree Trefoil of *Crete*, with Pods covered with a thick long hoary Down.

24. Cytisus *orientalis minimus humifuſus. Tourn. Cor.* The leaſt low *Eaſtern* Baſe-tree Trefoil.

25. Cytisus *orientalis humifuſus, flore magno ex luteo purpuraſcente. Tourn. Cor.* Low *Eaſtern* Baſe-tree Trefoil, with a large purpliſh yellow Flower.

26. Cytisus *orientalis humifuſus, facie trifolii pratenſis. Tourn. Cor.* Low *Eaſtern* Baſe-tree Trefoil, with the Appearance of Meadow Trefoil.

27. Cytisus *foliis argenteis. Wheel. Itin.* Silvery Baſe-tree Trefoil of Sir *George Wheeler.*

28. Cytisus *orientalis, medicæ foliis incanis & villoſis, flore flaveſcente. Tourn. Cor. Eaſtern* Baſe-tree Trefoil, with hoary and hairy Leaves, and a yellowiſh Flower.

29. Cytisus *orientalis latifolius ſubtus incanus. Tourn. Cor. Eaſtern* Baſe-tree Trefoil, with broad Leaves, which are hoary underneath.

30. Cytisus *Africanus argenteus, flore atropurpureo. Oldenl.* Silvery *African* Baſe-tree Trefoil, with a dark purple Flower.

31. Cytisus *Africanus hirſutus anguſtifolius. Oldenl.* Hairy *African* Baſe-tree Trefoil, with narrow Leaves.

32. Cytisus *Americanus ſpinoſus, floribus luteis ad alas naſcentibus. Plum. Cat.* Prickly *American* Baſe-tree Trefoil, with yellow Flowers growing at the Wings of the Leaves.

33. Cytisus *Americanus fruteſcens ſericeus. Plum. Cat.* Shrubby-ſilky *American* Baſe-tree Trefoil.

34. Cytisus *Americanus arboreſcens, fructu eduli albo. Plum. Cat. American* Tree-like Baſe-tree Trefoil, with a white eatable Fruit, commonly called the *Pigeon Pea* in *America*.

The firſt, ſecond, and third Sorts grow to be large Trees, and are therefore proper for large Quarters of Flowering-trees, eſpecially the firſt, which will grow to be eighteen or twenty Feet high: Their Seaſon of Flowering is in *May*, at which Time they afford a very agreeable Proſpect, eſpecially that Sort with long pendulous Flowers, which is by far the moſt beautiful Kind.

Theſe are all propagated by ſowing their Seeds (which they afford in Plenty) in *March* on a Bed of good freſh light Earth, ſifting a little Mould over them about half an Inch thick, and in about a Month's Time the Plants will come up; you muſt therefore keep them clear from Weeds, and if the Seaſon ſhould prove dry, you muſt often refreſh them with Water, which will greatly promote their Growth: In this Bed they may remain until *March* following, when you may tranſplant them into a Nurſery, in Rows three Feet Diſtance, and one Foot aſunder in the Rows, being careful not to break the Roots, which are very tender, as alſo to water and mulch their Roots, to prevent the Sun and Wind from drying their Fibres: This Nurſery muſt alſo be kept very clear from Weeds, and every Spring the Ground between the Rows ſhould be dug, to looſen the Earth, and deſtroy the Weeds. In this Nurſery they may remain two or three Years, according to the Progreſs they make, or the Ground where they are to be planted is ready; but however if they ſtand longer than three Years, every other Tree ſhould be remov'd, or elſe they ſhould at firſt be planted at a much greater Diſtance; for otherwiſe their Roots will intermix, and render it difficult to remove them ſafely. The Seaſon for tranſplanting theſe Trees, is either in *October* or *February*, obſerving to mulch and water them as before.

The fourth ſeldom riſes with us to be above five or ſix Feet high, and may be kept to a regular Head: This ſhould therefore be planted in ſmaller Quarters, with Shrubs of the ſame Growth. It flowers in *June*, at which Time it makes an agreeable Figure, for the Flowers are produc'd in large Cluſters very cloſe together, ſo that the whole Shrub is cover'd with them. This may be propagated in the ſame Manner as the former.

The fifth Sort is tender, and requires a Green-houſe in Winter, where it ſhould be plac'd to have as much open free Air as poſſible when the Weather is good, but muſt be ſcreen'd from Froſt, and cold nipping Winds: In the Summer it may be expos'd abroad, with *Oranges*, *Myrtles*, &c. It ſhould have a freſh light Soil, and frequent Waterings in that Seaſon. This Plant may be either propagated by Seeds, (which ſhould be ſown on a Hot-bed in the Spring; and when the Plants come up, they may be planted into ſmall Pots, and manag'd as directed for the *African Tree-Milkwort*) or by Layers, which ſhould be laid down in the Spring; and if kept duly water'd, will take Root againſt the ſucceeding Spring, when they may be taken off and tranſplanted into Pots, which ſhould be fill'd with the ſame light Soil as was before directed, ſetting the Pots into a ſhady Place until the Plants have taken freſh Root; after which Time they may be expos'd with the old Plants, and manag'd as directed for them.

The ſixth Sort is very common in the Nurſeries about *London*; where it is ſold with other flowering Shrubs, to intermix in planting Wilderneſs Quarters. This may be eaſily propagated by the Seeds, which it produces every Year in great Plenty; which ſhould be ſown on a Bed of light Earth in *March*, and a little Earth ſifted over the Seeds, ſo as to cover them about half an Inch. In the Beginning of *May* the Plants will begin to appear, when they ſhould be carefully clear'd from Weeds, and in very dry Weather they muſt be refreſhed with Water. In this Bed the Plants may remain till the following Spring, always obſerving to keep them clear from Weeds; which, if ſuffer'd to overbear the Plants while young, will either totally deſtroy them, or very much retard their Growth. The Spring following they may be tranſplanted out into Beds of freſh Earth the Beginning of *March*, placing them about a Foot aſunder; being careful that the Plants are not kept above Ground, but planted as ſoon as they are taken up; otherwiſe the Fibres of the Roots will ſoon dry, which is very prejudicial to young Plants. In theſe Beds they may remain two Years; after which Time they ſhould either be planted out where they are to remain, or elſe tranſplanted into a Nurſery, placing them in Rows three Feet aſunder, and eighteen Inches Diſtance in the Rows; where they may continue until the Ground is ready where they are deſigned to remain. This Plant is very hardy, and will form a handſome Shrub about five or ſix Feet high, and is very proper to place amongſt flowering Shrubs of the ſame Growth. It flowers plentifully in *June*, and the Seeds are ripe in *Auguſt*.

The ſeventh, eighth, and ninth Sorts are ſomewhat tenderer than the former, and will not abide the open Air in *England* in ſevere Winters. Theſe may be all propagated by ſowing of their Seeds on a moderate Hot-bed in the Spring; and when the Plants are come up, they ſhould be tranſplanted each into a ſeparate Halfpenny Pot, filled with freſh Earth, and plunged in a moderate Hot-bed, obſerving to water and ſhade them until they take Root; after which they muſt be inured to the open Air by Degrees; and in *June*, the Pots ſhould be removed and placed abroad in a Situation where they may be defended from ſtrong Winds, where they may remain until the Middle of *October*; when they ſhould be removed either into an airy Green-houſe, or placed under a common Hot-bed Frame; where they ſhould have as much free Air as poſſible in Winter, for they only require to be defended from hard Froſts; and if they have not much Air, they will draw very weak, and become tender and unſightly. Theſe Plants ſhould be removed into larger Pots the Spring following; and ſo from Year to Year, as they increaſe in Size, they ſhould have larger Pots: in Summer they muſt be kept as long abroad as the Seaſon will permit, and in Winter ſhould have as much Air as poſſible in mild Weather; with which Management they will thrive, and produce great Plenty of Flowers. When theſe Plants are become woody, they may be ſhaken out of the Pots, and planted in the open Air in a warm Situation, where they will endure the Cold of our ordinary Winters very well, and flower and produce ripe Seeds every Year, much better than thoſe which are confined in Pots: but it will be proper to keep one Plant of each Kind in Pots, becauſe a very ſevere Winter may deſtroy thoſe which ſtand abroad; ſo their Kinds may be loſt, unleſs there is one of each Kind preſerved by ſheltering of them in Winter.

The thirteen Sorts next following of theſe, are ſome of them more tender than the four laſt mentioned; ſo that there will be a Neceſſity of preſerving ſome of them in Pots, that they may be ſheltered in Winter. All theſe Sorts may be propagated in the ſame Manner as the former.

The twenty-third, twenty-fourth, twenty-fifth, twenty-ſixth, twenty-ſeventh, twenty-eighth and twenty-ninth Sorts, are leſs common than the former; theſe grow in the Iſlands of the *Archipelago*, from whence their Seeds may be procured: theſe Seeds ſhould be ſown in the Spring, on a very moderate Hot-bed; and when the Plants are come up, they ſhould be carefully tranſplanted, each into a ſeparate ſmall Pot, filled with freſh light Earth; then place them where they may be ſheltered from the Sun until they have taken new Roots, after which Time they may be removed into a warm Situation, where they may be defended from ſtrong Winds, obſerving to water them conſtantly in dry Weather. In Winter theſe Plants ſhould be placed under a Hot-bed Frame, where they may be ſheltered from Froſt, but they ſhould be every Day expoſed to the open Air in mild Weather; for they are hardy enough to bear the open Air of this Country, except in very cold Weather; and if they are kept too tender, they will draw up very weak, ſo that they will not produce their Flowers.

The following Spring, ſome of theſe Plants ſhould be ſhaken out of the Pots, and planted in a warm Situation in the full Ground; where they will thrive very well, and produce their Flowers every Spring, and ſome of them will perfect their Seeds; but it will be proper to preſerve a Plant or two of each Kind in Pots, that may be ſheltered in Winter; becauſe thoſe abroad may be deſtroyed by ſevere Froſt. Theſe Plants make a fine Diverſity amongſt flowering Shrubs of a middling Growth; ſo that they deſerve a Place in every good Garden.

The two *African* Sorts are yet tenderer than either of the former; theſe will not bear the open Air of our Country in Winter, ſo muſt be conſtantly preſerved in Pots, and removed into the Green-houſe in Winter, where they ſhould be placed ſo as to enjoy as much free Air as poſſible in mild Weather; otherwiſe they will ſhoot very weak, and become unſightly: nor will they produce their Flowers in near ſo great Plenty, as when they are expoſed to Air as much as poſſible in mild Weather.

Theſe Sorts are propagated by Seeds, which ſhould be ſown early in the Spring, in Pots filled with light freſh Earth, which ſhould be plunged into a Hot-bed of Tanners-bark, obſerving to water them gently as the Earth may require. When the Plants are come up two Inches high, they ſhould be carefully tranſplanted, each into a ſeparate ſmall Pot, which ſhould be plunged into a moderate Hot-bed, obſerving to ſcreen them from the Sun until they have taken new Roots; after which Time the Glaſſes of the Hot-bed ſhould be raiſed every Day, to admit freſh Air to the Plants; and they muſt be duly watered three or four times a Week in warm Weather. By the Beginning of *June*, theſe Plants will have acquired ſome Strength; then they ſhould be inured to bear the open Air by Degrees; and toward the End of *June*, if the Seaſon proves warm, the Plants ſhould be removed out of the Hot-bed, and placed in a warm Situation, where they may remain until *October*; when they muſt be removed into Shelter, placing them near the Windows of the Green-houſe, that they may enjoy a large Share of Air. During the Winter Seaſon, theſe Plants muſt be frequently watered, but they muſt not have too much given them at a Time, leſt it rot the Fibres of their Roots. In Summer they muſt be expoſed again, with other exotic Plants, in a ſheltered Situation, where they may be defended from ſtrong Winds; and as the Plants increaſe in Size, ſo they muſt be put into larger Pots; but they muſt not be allowed Pots too large, for in theſe they will not thrive.

The thirty-ſecond and thirty-third Sorts are yet more tender than the laſt mentioned; theſe being Natives of the warm Parts of *America*, will not live in this Climate, unleſs they are preſerved in the warmeſt Stoves. They are propagated by Seeds, which ſhould be ſown early in the Spring, in Pots filled with rich light Earth, and plunged into a Hot-bed of Tanners-bark. When the Plants are come up about three Inches high, they ſhould be each tranſplanted into a ſmall Pot, filled with light freſh Earth, and plunged again into the Hot-bed, obſerving to ſhade them until they have taken Root again; then in warm Weather, the Glaſſes of the Hot-bed ſhould be raiſed every Day to admit freſh Air, in proportion to the Warmth of the Seaſon; and they muſt be frequently watered in hot Weather. Theſe Plants may remain in the Hot-bed during the Summer Seaſon, but in Autumn they muſt be removed into the Stove, and plunged into the Bark-bed; where if they are duly watered, and the Stove kept to a temperate Heat, they will thrive exceeding well. Theſe Plants will not live in the open Air in this Country at any Seaſon of the Year, ſo they ſhould always remain in the Stove, being careful to admit freſh Air to the Plants in warm Weather, by opening the Glaſſes of the Stove; and as the Plants advance, ſo they ſhould be removed into larger Pots: With this Management, the Plants will continue many Years, and produce their Flowers, which will afford an agreeable Variety amongſt other Plants of the ſame Country.

The thirty-fourth Sort is preſerved as a Curioſity in *Europe*, but in the *Weſt-Indies* it is frequently planted by the Sides of Allies in Gardens, to form a Hedge, where they will laſt many Years without decaying; and will thrive on barren Land, which has been worn out, where ſcarcely any other Plant will proſper. It produces great Quantities of Fruit, which are ſometimes eaten by the Inhabitants; but their chief Uſe is to feed Pigeons, from whence this Plant had its Name. The Branches, with the ripe Peaſe and Leaves, are given to Hogs, Horſes, and moſt other Cattle, which fattens them very much.

In *England*, it is preſerved by ſome curious Perſons in the Stove, being too tender to live thro' the Winter in this Climate without artificial Warmth. This Plant may be propagated by ſowing of the Seeds on a Hot-bed early in the Spring; and when the Plants are come up, they ſhould be each tranſplanted into a Half-penny Pot, filled with freſh light Earth, and plunged into a Hot-bed of Tanners-bark, obſerving to ſhade them until they have taken Root; after which Time they ſhould have a large Share of freſh Air admitted to them in warm Weather, and muſt be frequently refreſhed with Water: When the Plants have filled theſe Pots with their Roots, they ſhould be ſhifted into larger, and plunged into the Hot-bed again, treating them as before: In this Bed they may remain till they are too tall to ſtand under the Glaſſes, when they ſhould be removed into the Stove, and plunged into the Bark-bed; where during the Winter Seaſon they ſhould have a moderate Heat, and be frequently watered. The Spring following they will produce Flowers, and if they are preſerved in the Stove, will perfect their Fruit in Summer.

DA

DAFFODIL. *Vide* Narciſſus.

DAISIES. *Vide* Bellis.

DALECHAMPIA.

This Plant was ſo named by Father PLUMIER, *in Honour to the Memory of* JACOBUS DALECHAMP, *who was a curious Botaniſt.*

The *Characters* are;

It hath Male and Female Flowers on the ſame Plant, which are contain'd in a many-leav'd prickly Cup; the Female Flowers, with the Embryo's, have two trifid Leaves; the Male Flowers conſiſt of a great Number of Stamina, which are loaded with Farina: the Embryo afterward becomes a Fruit, which is divided into three Parts, each containing one roundiſh Seed.

We have but one *Sort* of this Plant, which is;

DALECHAMPIA *ſcandens, lupuli foliis, fructu tricocco glabro, calyce hiſpido. Houſt.* Climbing Dalechampia, with Leaves like Hops, a ſmooth three-ſeeded Fruit, and a prickly Cup.

This Plant is a Native of the warm Parts of *America*; it was diſcovered by Father *Plumier* in *Martinico*; but either he has miſtaken in his Deſcription of the Fruit, or his Kind is different from that which the late Dr. *Houſtoun* obſerved in ſeveral Places in the *Spaniſh Weſt-Indies*; for Father *Plumier* deſcribes the Fruit to be prickly, in the Sort which he ſaw; whereas that of Dr. *Houſtoun* has ſmooth Fruit incloſed in a prickly Cup.

This Plant is propagated by Seeds, which muſt be ſown early in the Spring on a Hot-bed: and when the Plants are come up three Inches high, they ſhould be carefully tranſplanted, each into a ſeparate ſmall Pot, filled with light rich Earth, and then plunged into a Hot-bed of Tanners-bark; being careful to ſcreen them from the Sun, until they have taken new Root; after which Time, the Glaſſes of the Hot-bed ſhould be raiſed every Day, in proportion to the Heat of the Weather, to admit freſh Air to the Plants: They muſt alſo be frequently watered, for they naturally grow in moiſt Places. When the Plants have grown ſo large as to fill theſe Pots with their Roots, they ſhould be removed into larger Pots, and placed in the Bark-bed in the Stove; where they muſt be ſupported either with Stakes, or a Trellace, round which they will twine, and riſe to the Height of eight or ten Feet.

Theſe Plants muſt be kept conſtantly in the Stove, for they are too tender to bear the open Air in this Country, even in the Summer Seaſon. Therefore they ſhould be placed with *Convolvulus's*, and other twining Plants, near the Back of the Stove, where ſhould be made an Eſpalier to ſupport them; in which Situation they will thrive and produce their Flowers, and ſometimes will perfect their Seeds in this Country. But in order to this, they ſhould have a large Share of free Air in warm Weather, by drawing down the upper Glaſſes of the Stove; but in Winter the Stove ſhould be kept to a temperate Heat, or rather higher. In Summer they will require a large Share of Water, but in Winter it ſhould be given to them in leſs Quantities, but muſt be frequently repeated. Theſe Plants do not continue above two or three Years; ſo that young Plants ſhould be raiſed in order to preſerve the Kind.

DAMASONIUM, Star-headed Water-plantain.

The *Characters* are;

It hath a Flower compoſed of three Leaves, which are placed orbicularly, and expand in Form of a Roſe; out of the Flower-cup riſes the Pointal, which afterward becomes a ſtar-ſhaped Fruit, with many Cells, which are full of oblong Seeds.

The *Species* are;

1. DAMASONIUM *ſtellatum. Lugd.* Star-headed Water-plantain.

2. DAMASONIUM *Americanum maximum, plantaginis folio, flore flaveſcente, fructu globoſo. Plum.* Greateſt *American* Water-plantain, with a Plantain Leaf, a yellowiſh Flower, and a globular Fruit.

The firſt of theſe Plants is a Native of *England*, it grows commonly in ſtanding Waters, which are not very deep. It is ſometimes uſed in Medicine, but never cultivated in

Gardens, ſo muſt be gathered for Uſe in the Places of its Growth.

The ſecond Sort grows in *Jamaica*, *Barbados*, and ſeveral other Places in the warm Parts of *America*, where it is generally found in ſtagnating Waters, and other ſwampy Places: ſo that it would be difficult to preſerve this Plant in *England*; for it will not live in the open Air, and requires a Bog to make it thrive. But as it is a Plant of no great Beauty or Uſe, ſo it is not worth the Trouble of cultivating in this Country.

DANDELION. *Vide* Dens Leonis.

DATE-TREE. *Vide* Palma.

DAUCUS; [δαῦκος, which ſome derive of δαίω, Gr. *to burn*, of its ſharp and fiery Power, or fervent Taſte.] The Carrot.

The *Characters* are;

It hath for the moſt part a fleſhy Root; the Leaves are divided into narrow Segments; the Petals of the Flower are unequal, and ſhap'd like a Heart; the Umbel when ripe is hollow'd and contracted, appearing ſomewhat like a Bird's Neſt; the Seeds are hairy, and in Shape of Lice.

The *Species* are;

1. DAUCUS *vulgaris. Cluſ.* Common wild Carrot.
2. DAUCUS *ſylveſtris humilior, latiore folio.* Dwarf wild Carrot, with broader Leaves.
3. DAUCUS *ſativus, radice atro-rubente. Tourn.* Dark red-rooted Garden-Carrot.
4. DAUCUS *ſativus, radice aurantii coloris. Tourn.* The Orange-colour'd Carrot.
5. DAUCUS *ſativus, radice alba. Tourn.* The White Carrot.

The firſt of theſe Species grows wild upon arable Land in moſt Parts of *England*, and is ſeldom cultivated except in Botanick Gardens. This is the particular Sort which ſhould be us'd in Medicine, and for which the Druggiſts commonly ſell the Seeds of the Garden *Carrot*.

The ſecond Sort was found by Mr. *Rand*, near *Dover*, and is ſpecifically different from the common Sort, as hath been prov'd by ſowing them together in a Garden for ſeveral Years.

The fourth Sort is commonly cultivated in Gardens for the Kitchen; as is the fifth Sort, tho' not ſo common in *England* as the former: nor would they be worth the Gardeners while to propagate them; for their pale Colour would render them leſs acceptable in the Markets, where the deepeſt-colour'd *Carrots* are always moſt eſteem'd, tho' for the Table, the White is generally preferr'd as the ſweeteſt.

They are propagated at two or three different Seaſons, or ſometimes oftener, where People are fond of young *Carrots* through all the Summer Months. The firſt Seaſon for ſowing the Seeds, is ſoon after *Chriſtmas*, if the Weather is open, which ſhould be in warm Borders, under Walls, Pales, or Hedges, but they ſhould not be ſown immediately cloſe thereto; but a Border of *Lettuce*, or other young Sallad-herbs, of about ſix or eight Inches wide, ſhould be next the Wall, *&c.* for if the *Carrots* were ſown cloſe to the Wall, they would run up to Seed without making any tolerable Roots.

Theſe delight in a warm ſandy Soil which is light, and ſhould be dug pretty deep, that the Roots may the better run down; for if they meet with any Obſtruction, they are very apt to grow forked, and ſhoot out lateral Roots, eſpecially where the Ground is too much dung'd the ſame Year that the Seeds are ſown, which will alſo occaſion their being Worm-eaten; it is therefore the better Method to dung the Ground intended for *Carrots* the Year before they are ſown, that it may be conſum'd and mix'd with the Earth.

Theſe Seeds have a great Quantity of ſmall forked Hairs upon their Borders, by which they cloſely adhere, ſo that they are difficult to ſow even ſo as not to come up in Patches; you ſhould therefore rub it well through both Hands, whereby the Seed will be ſeparated before it is ſown: then you ſhould chuſe a calm Day to ſow it, for if the Wind blows, it will be impoſſible to ſow it equal; for the Seeds being very light, will be blown into Heaps: When the Seed is ſown, you ſhould tread the Ground pretty cloſe with your Feet, that it may be buried, and then rake the Ground level.

When the Plants are come up, you ſhould hough the Ground with a ſmall Hough about three Inches wide, cutting down all young Weeds, and ſeparating the Plants to four Inches Diſtance each way, that they may get Strength; and in about three Weeks after, when the Weeds begin to grow again, you ſhould hough the Ground over a ſecond time, in which you ſhould be careful not to leave two *Carrots* cloſe to each other, as alſo to ſeparate them to a greater Diſtance, cutting down all Weeds, and ſlightly ſtirring the Surface of the Ground in every Place, the better to prevent young Weeds from ſpringing, as alſo to facilitate the Growth of the young *Carrots*.

In about three Weeks or a Month after, you muſt hough them a third time, when you muſt clear the Weeds as before; and now you ſhould cut out the *Carrots* to the Diſtance they are to remain, which muſt be proportion'd to the Size you intend to have them grow: If they are to be drawn while young, five or ſix Inches aſunder will be ſufficient; but if they are to grow large before they are pull'd up, they ſhould be left eight or ten Inches diſtant every way: You muſt alſo keep them clear from Weeds, which if ſuffer'd to grow amongſt the *Carrots*, will greatly prejudice them.

The ſecond Seaſon for ſowing theſe Seeds is in *February*, on warm Banks ſituated near the Shelter of a Wall, Pale or Hedge; but thoſe which are intended for the open large Quarters, ſhould not be ſown before the Beginning of *March*, nor ſhould you ſow any later than the End of the ſame Month; for thoſe which are ſown in *April* or *May* will run up to Seed before their Roots have any Bulk, eſpecially if the Weather ſhould prove hot and dry.

In *July* you may ſow again for an autumnal Crop, and in the End of *Auguſt* you may ſow ſome to ſtand the Winter; by which Method you will have early *Carrots* in *March*, before the Spring-ſowing will be fit to draw; but theſe are ſeldom ſo well taſted, and are often very tough and ſticky. Many People mix ſeveral other Sorts of Seeds, as *Leek*, *Onion*, *Parſnip*, *Radiſh*, &c. amongſt their *Carrots*; and others plant *Beans*, &c. but, in my Opinion, neither of theſe Methods is good; for if there is a full Crop of any one of theſe Plants, there can be no Room for any thing elſe amongſt them, ſo that what is got by the one is loſt by another; and beſides, it is not only more ſightly, but better for the Plants of each Kind to be ſown ſeparate, and alſo by this Means your Ground will be clear when the Crop is gone, to ſow or plant any thing elſe; but when three or four Kinds are mix'd together, the Ground is ſeldom at Liberty before the ſucceeding Spring: Beſides, where Beans, or any other tall growing Plants are planted amongſt the *Carrots*, it is apt to make them grow more in Top than Root, ſo that they will not be half ſo large as if ſown ſingly without any other Plants amongſt them.

But in order to preſerve your *Carrots* for Uſe all the Winter and Spring, you ſhould, about the Beginning of *November*, when the green Leaves are decay'd, dig them up, and lay them in Sand in a dry Place, where the Froſt can't come to them, taking them out from time to time as you have occaſion for them, reſerving ſome of the longeſt and ſtraiteſt Roots for Seed, if you intend to ſave any; which Roots ſhould be planted in the Middle of *February*, in a light Soil, about a Foot aſunder each way, obſerving to keep the Ground clear from Weeds; and about the Middle of *Auguſt*, when you find the Seeds are ripe, you muſt cut it off, and carry it to a dry Place, where it ſhould be expos'd to the Sun and Air for ſeveral Days to dry; then you may beat out the Seeds, and put it up in Bags, keeping it in a dry Place until you uſe it. This Seed is ſeldom eſteem'd very good after the firſt or ſecond Year at moſt; but new Seed is always preferr'd, nor will it grow when it is more than two Years old.

DAUCUS CRETICUS. *Vide* Myrrhis.

DAY-LILY. *Vide* Liliaſtrum.

DECEMBER.

Work to be done in the KITCHEN GARDEN.

This Month (the Days being at the ſhorteſt) is the darkeſt of the whole Year, and is ſubject to different Sorts of Weather; ſometimes the Ground is frozen up, ſo that little can be done in the Garden; and at other times there are hard Rains, and thick ſtinking Fogs, which render it very uncomfortable ſtirring abroad, and are very injurious to tender Plants.

If the Seaſon be mild, you may earth up thoſe Artichokes which were neglected the former Months; in doing of which you ſhould bury a little rotten Dung in the Ground, which will greatly promote the Growth of your Artichokes the following Spring.

Carry Dung into the Quarters of your Kitchen-garden, and ſpread it on the Ground, and trench up the Quarters, laying the Earth in Ridges, that it may be mellow'd by Froſt, and be fit for Uſe when the Seaſon for cropping them comes on;

for if you do not get your Ground in Readineſs at this Seaſon, you will have too much Buſineſs hurrying upon you in the Spring.

Pick Snails out of the Holes of old Walls, or from under Pales, Hedges, broken Pots, or other Rubbiſh, in which Places they lay themſelves up during the Winter-ſeaſon, and may be then eaſily taken before they get abroad again.

Sow Creſſes, Muſtard, Rape, Radiſh, Turnep, and other Sallet-herbs, upon a moderate Hot-bed, which ſhould be either cover'd with Frames, or arch'd over with Hoops, and cover'd with Mats; for at this Seaſon theſe Seeds will not come up where they are expoſed to the open Air.

In mild Weather you ſhould obſerve to uncover your Cauliflower Plants every Day, that they may enjoy the free Air, otherwiſe they will draw up weak, and be good for little; you muſt alſo conſtantly pick off all decay'd Leaves, which if ſuffer'd to remain on, will be very injurious to the Plants, eſpecially if it ſhould happen that the Weather will not permit the Beds to be uncovered for two or three Days together, which is often the Caſe at this Seaſon, when theſe decay'd Leaves, rotting in the Beds, will emit a rancid Vapour, which mixing with the confin'd Air of the Beds, will render it unwholſome for the Plants.

You may now make Hot-beds for Aſparagus to ſupply the Table about the latter End of *January*; for at this Seaſon it will be near ſix Weeks from the Time of making the Beds, before the Aſparagus will be fit to cut.

About the Middle of this Month, if Weather is mild, you ſhould ſow ſome early Peaſe, on warm Borders, to ſucceed thoſe which were ſown the former Months, and obſerve to draw ſome Earth up about the Stems of thoſe Peaſe and Beans which are come up, to protect them from the Froſt.

You may alſo ſow ſome Radiſhes, Carrots, and Lettuce, on warm Borders, near Walls or Pales, for an early Crop, becauſe it may happen that thoſe which were ſown the former Months may be deſtroy'd, and theſe eſcape; for which Reaſon it is proper always to have two or three Crops, one under the other, which will allow you a better Chance than if you had but one.

Toward the latter End of this Month you ſhould plant ſome *Sandwich* Beans, which are hardier than the *Windſor* Kind, and will be very proper to ſucceed the *Spaniſh* or *Liſbon* Beans, which were planted the former Months, ſo that there may be a conſtant Supply for the Table.

When the Ground is frozen ſo hard that you cannot dig it, you ſhould repair your Fences, and carry Dung upon your Quarters, that it may be ready when the Froſt goes off; you ſhould alſo clean your Seeds ready for ſowing, and prepare all your Tools, that there may be no Delay when the Seaſon is favourable for cropping your Ground.

Products of the KITCHEN-GARDEN.

Cabbages, Savoys, Red Cabbages, Borecole, and ſome Broccoli, Carrots, Parſnips, Turneps, Potatoes, Skirrets, Scorzonera, Salſafy, Beets, and Horſe Radiſh.

Onions, Leeks, Garlick, Rocambole, Shallots, Thyme, Winter Savory, Hyſſop, Sage, Roſmary, Chard Beets, Chardoons, Celery, and ſome other Herbs for Soop.

Creſſes, Muſtard, Rape, Radiſh, Turnep, ſmall Lettuce, and other Sallet-herbs upon the Hot-bed; Celery, Endive, and ſome Brown Dutch Lettuce, from under Glaſſes in mild Weather, with Mint and Tarragon upon Hot-beds made the Beginning of laſt Month, and Aſparagus upon Hot-beds made in *October*.

Work to be done in the FRUIT GARDEN *and* ORCHARD.

If the Seaſon be mild, you may dig and prepare your Ground for planting Fruit-trees in *February*, and mend the Borders of your Fruit-garden with ſome freſh Earth and very rotten Dung well mixed together, which will greatly encourage your Trees.

It will not be proper to prune any of your Fruit-trees either againſt Walls or Eſpaliers at this Seaſon, leſt the Froſt ſhould follow ſoon after, which would injure the wounded Branches, eſpecially of Peaches, Apricocks, and other tender Fruit-trees.

Examine your Orchards, and cut all dead Branches out of the Trees, as alſo ſuch as croſs each other; in doing of which you ſhould obſerve to make the Wound ſloping, and as ſmooth as poſſible, that the Wet may the eaſier paſs off without entring the Tree.

You may alſo dung and plough the Ground of your Orchards between the Trees, which will be of great Service to them, and cauſe the Fruit to be much fairer, and better taſted; and when you intend to plant any young Orchards in the Spring, the Ground ſhould now be prepared for that Purpoſe.

In froſty Weather you ſhould be careful to cover the Ground about your new-planted Trees with Mulch, to prevent the Froſt from penetrating the Ground to their Roots, for that would greatly injure the young Fibres.

You muſt alſo be very careful to keep the Froſt out of the Room where you keep your choice Winter Fruit; for whenever any of the Fruit are frozen, they certainly decay ſoon after.

Fruits in prime, or yet laſting.

Pears; the Colmar, St. Germain, St. Andrew, Virgouleuſe, Ambrette, Leſchaſſerie, Epine d'Hyver, St. Auguſtine, Beurre d'Hyver, Louiſe-Bonne, l'Amodotte, Spaniſh Boncretien, Poire de livre, Ronville, Citron d'Hyver, Rouſelette d'Hyver, Martin Sec, with ſome others.

Apples; the Nonpareil, Golden Pippen, *French* Pippen, *Holland* Pippen, *Kentiſh* Pippen, Pile's Ruſſet, Winter Pearmain, Wheeler's Ruſſet, Haut-bonne, Rennet Griſe, Aromatick Ruſſet, Winter Gilliflower, Golden Ruſſet, Pear Ruſſet, Harvey Apple, Winter Queening, with ſome others of leſs Note.

As alſo Medlars, Services, Almonds, and Nuts.

Work to be done in the NURSERY.

In this Month and the next it is very unſafe to tranſplant Trees; therefore little can be done in the Nurſery, except carrying in Dung where it is wanted; and in mild Weather to prepare the Ground, where you intend to plant Trees in the Spring.

Obſerve now to lay Mulch about the Stems of your new-planted Trees, where it has been omitted in the former Months; otherwiſe the Froſt will enter the Ground, and pinch all the new Fibres, whereby the Trees will be greatly weaken'd.

In froſty Weather look well to ſuch Nurſeries as are expoſed to Hares, Rabbits, *&c.* for in ſuch Seaſons theſe Animals will be apt to bark your young Trees, and ſpoil them.

Obſerve alſo to ſecure ſuch young Exotick Trees as have not Strength to reſiſt the Cold of our Climate, by laying Mulch round their Stems, and in ſevere Froſt, cover their Tops with Peaſe-haulm; but this muſt not remain after the Froſt is over, leſt it cauſe a Mouldineſs upon the tender Parts of the Plants for want of the free Air.

Be careful to cover your Beds of Seeds and Acorns, which were ſown in *October*, to prevent the Vermin from getting at them, and to keep the Froſt out of the Ground, which might greatly injure ſuch of them as are ſprouting.

Work to be done in the PLEASURE GARDEN.

Your Beds of choice Ranunculus's, Anemonies, and Hyacinths ſhould be carefully covered in very wet or froſty Weather, both which are equally prejudicial to them.

The Pots or Boxes of ſeedling Flowers ſhould alſo be covered in very hard Rains, or ſevere Froſt, otherwiſe they will be in Danger of being deſtroyed thereby.

Cover your choice Carnations and Auricula's, to protect them from great Rains and Snow, which are very injurious to them; but in mild Weather they ſhould have as much free Air as poſſible, otherwiſe they will draw up weak, and become very tender.

You ſhould now lay ſome Mulch about the Roots of your new-planted Trees and Shrubs, as alſo about your exotick Trees which are planted in the open Air, to prevent the Froſt from penetrating the Ground to their Roots, which would greatly injure, if not deſtroy them.

Turn over your ſeveral Heaps of Earth which are prepared for the Flower-Garden, that the Froſt may mellow them; and mix up ſome new Heaps, that you may have a Quantity always prepared eight or ten Months at leaſt before you uſe them.

In mild Weather you ſhould dig and prepare your Beds and Borders ready for planting Flower-roots in the Spring, in doing of which it will be proper to lay the Earth up in a Ridge, that the heavy Rains may run off, which would render the Earth too wet for planting, if the Beds were laid flat to receive them.

Continue to dig up the Ground in your Wilderneſs Quarters, that the whole may be render'd neat againſt the next Spring, when the Trees begin to bud, and the Flowers blow, which will invite Perſons to walk out; but in doing of this, you muſt be careful not to injure any of the Plants which grow between the Trees.

Prepare ſuch Parts of your Garden where you intend to plant flowering Shrubs or tender Trees out in the Spring ; but this Ground ſhould be laid in Ridges till the Seaſon for planting is come.

In froſty Weather, when you can do little Work in the Garden, you muſt prepare your Tallies to number your Flowers and Seeds when they are ſown, and make all your Tools ready for Uſe againſt Spring, when you will have full Employment abroad.

Plants now in Flower in the open Air.

Some Single Anemonies, Polyanthus's, Primroſes, Stock-Gilliflowers, Polyanthus Narciſſus, Helleboraſter, or Bears-foot, Alyſſon Halimi folio, Red-flower'd Spring Cyclamen, Tangier Fumatory, Narrow-leav'd Golden Rod, and in mild Weather ſometimes the Winter Aconite, and Snow-drops.

Hardy Trees and Shrubs now in Flower.

Lauruſtinus, Arbutus or the Strawberry-tree, Spurge Laurel, Glaſtenbury Thorn, Virginian Groundſel-tree, Upright blue-berried Honeyſuckle, Geniſta Spinoſa, Clematitis Bœtica, Cytiſſus Maranthe, and in mild Weather the Mezereon.

Work to be done in the GREEN-HOUSE *and* STOVE.

If the Seaſon be very cold, you muſt keep the Windows and Doors of your Green-houſe cloſely ſhut ; but in mild Weather you ſhould open ſome of them, to let freſh Air into the Houſe, otherwiſe there will be a damp moiſt Air, which will cauſe the tender Shoots of the Plants to grow mouldy and decay ; therefore whenever you obſerve any Mouldineſs upon your Plants, you muſt immediately clean it off, otherwiſe it will ſpread, and infect the neighbouring Plants ; you muſt alſo diligently pick off all decay'd Leaves, and not permit them to fall off upon the Floor ; becauſe, if they remain in the Houſe, they will rot, and infect the Air, to the great Injury of your Plants.

You muſt now water your Plants very ſparingly, eſpecially ſuch of them as are of a ſucculent Nature, as Aloes, Cereus's, Ficoides's, Sedums, Cotyledons, *&c.* but your Myrtles, Amomum Plinii's, Leonurus's, Oleanders, Bays, Adhatoda, with other woody Plants, muſt be frequently water'd ; but in cold Weather they ſhould not have too much given them at a Time, but rather give it to them often and in leſs Quantities.

The Fires in the Stoves muſt now be carefully kept up, as well in dark foggy Weather, as in ſevere Froſt ; for if the Air is damp, it is equally injurious as a ſharp Air to the Plants, ſo that you muſt be directed by a well graduated Thermometer, as to the Degree of Heat which your Plants require.

Your Anana or Pine-Apples muſt have a good Share of Heat, otherwiſe they will not produce Fruit the following Summer : you muſt alſo obſerve to refreſh them often with Water, which ſhould be placed in the Stove to warm, at leaſt twelve or fourteen Hours before it is uſed : Where this is neglected, the Plants are often ſo check'd as not to be recover'd in ſome Months after.

Your tender Exotick Plants, which are plunged in the Bark-bed, muſt now be carefully tended, to water them as they ſhall require it, and to pick off all decay'd Leaves, and cleanſe their Stems and Leaves from Inſects and Filth, which they are very ſubject to contract, eſpecially the Coffee-trees, which muſt be often clean'd, otherwiſe their Leaves will decay.

You muſt now mix up your ſeveral Compoſts of Earth for your Exotick Plants, and turn over thoſe Heaps which have been already prepared, that their ſeveral Parts may be better united together.

Plants now in Flower in the GREEN-HOUSE *and* STOVE.

Leonurus's, Candy-tuft-tree, Yellow Indian Jaſmine, Aleppo Cyclamens, Aſcyron Balearicum, Geraniums, Spaniſh Jaſmine, Arabian Jaſmine, Ilex-leav'd Jaſmine, Polygala Arboreſcens, Double-flower'd Indian Naſturtium, Onion-leav'd Aſphodel, ſeveral Sorts of Aloes, Anemonoſpermos's, Leuchanthemum Pyrethi ſapore, Carolina Dwarf Sunflower, Canary Campanula, Althæa Arboreſcens, Virginian large blue Aſter, Golden Rod, Senecio folio Retuſo, Alaternoides Ericæ folio, ſome Sorts of Ficoides's, Senſitive Plants, with ſome others.

DECORTICATION, the pulling off the outward Bark of Trees ; alſo the peeling or unhuſking of Roots.

DELPHINUM, [Δελφὶν, Gr. a *Dolphin* ; ſo call'd becauſe the Flower, before it opens, reſembles a Dolphin. It is call'd *Conſolida Regalis*, from its Conſolidating Virtue. *Caſpar Bauhin* calls it the Royal Plant, becauſe it has its Cup turn'd backwards, like a Nobleman's Badge. *Cæſalpinus*, *Pliny*, and the Poets, ſay, this Plant is the true Hyacinth, becauſe it has its Flower, *i. e.* the *Alpha* A, with the *Iota* I, placed over it ; and that *Apollo* begat *Hyacinthus*, when he ſent forth his laſt Breath : which Point is a Particle of Bewailing. *Ovid* is ſaid to have inſcribed his *Lamentations* in its Leaves. It is obſerv'd in this Plant, that when the Leaf is folded in, it has Characters conceal'd in the White. The *Germans* call it *Lauſkraut*, i. e. *Louſe-wort* ; becauſe, being powder'd, and ſtrew'd on the Head, it kills Lice] Larkſpur.

The *Characters* are ;

It hath an anomalous Flower, conſiſting of many diſſimilar Petals (or Flower-leaves), the uppermoſt of which is contracted, and ends in a Tail or Spur, and receives another bifid Petal, which, in like manner, ends in a Tail: In the Middle ariſes the Pointal, which becomes a Fruit, conſiſting of many Pods or Sheaths collected into a Head, which open likewiſe, and are fill'd with Seeds, which are for the moſt part angular.

The *Characters* are ;

1. DELPHINIUM *perenne montanum villoſum, aconiti folio. Tourn.* Perennial Mountain hairy Larkſpur, with a Monks-hood Leaf.

2. DELPHINIUM *latifolium, parvo flore. Tourn.* Broad-leav'd Larkſpur, with a ſmall Flower.

3. DELPHINIUM *platani folio, Staphiſagria dictum. Tourn.* Lark-ſpur with a Plane-Tree Leaf, *commonly call'd* Staveſacre, or Louſewort.

4. DELPHINIUM *ſegetum, flore cæruleo. Tourn.* Corn Larkſpur, with a blue Flower.

5. DELPHINIUM *vulgare, flore multiplici. Tourn.* Common Larkſpur, with a double Flower.

6. DELPHINIUM *hortenſe, flore majore & multiplici, cæruleo. Tourn.* Garden Larkſpur, with a large double blue Flower.

7. DELPHINIUM *hortenſe, flore majore & multiplici, incarnato. Tourn.* Garden Larkſpur, with a large double Fleſh-colour'd Flower.

8. DELPHINIUM *hortenſe, flore majore & multiplici, violaceo. Tourn.* Garden Larkſpur, with a large double Violet-colour'd Flower.

9. DELPHINIUM *hortenſe, flore majore & multiplici, rubro. Tourn.* Garden Larkſpur, with a large double red Flower.

10. DELPHINIUM *hortenſe, flore majore & multiplici, purpureo ex albo variegato. Tourn.* Garden Larkſpur, with a large double Flower of a purple Colour, variegated with White.

11. DELPHINIUM *hortenſe, flore roſeo punctato. Tourn.* Garden Larkſpur, with a ſpotted Roſe-colour'd Flower.

There are ſeveral other Varieties of this Plant, which differ either in the Colour or Size of their Flowers: But as moſt of them are accidental, and ariſe from Seeds of the ſame Plant, ſo I ſhall paſs them over, without enumerating all their minute Differences.

The firſt *Species* here mention'd is a Native of the *Alps*, and is remarkably different from the other Kinds of *Larkſpur*, in being an abiding Plant: This is propagated by ſowing the Seeds in an open light Soil in *March* ; and when the Plants are come up, they may be tranſplanted into ſhady Borders at a Foot Diſtance from each other, where they may ſtand until the ſecond Year ; by which Time they will have Strength to produce Flowers, and may then be tranſplanted into Borders in the Pleaſure-Garden, amongſt other Flowering Plants, where they will make a handſome Appearance when in Flower.

The ſecond Sort is not near ſo beautiful as the firſt, but is preſerv'd in curious Gardens of Plants, for its Variety. The Flowers of this Kind are very ſmall ; and it is commonly ſo late in the Seaſon before they are produced, that they ſeldom perfect their Seeds with us, unleſs the Plants come up in Autumn, and abide the Winter. The Seeds of this Plant I received from my Honour'd Friend Mr. *Henry Hopkey*, who gather'd it on *Gibraltar Hills*, where it grows wild.

The third Sort is the *Staveſacre*, the Seeds of which are uſed in Medicine : This is a large handſome Plant, and produces fair large Flowers : The Seeds of this ſhould be ſown in a light ſandy Soil, and a warm Situation, ſoon after it is ripe ; for if it be kept until Spring, it very often miſcarries. The ſecond Year after ſowing, it flowers, and ſoon after perfects its Seed, and dies. This Plant is at preſent very uncommon in *England*, and only to be found in ſome curious Gardens of Plants.

The other Sorts are commonly cultivated in Gardens, for the Beauty of their Flowers ; where, when the ſeveral Varieties

ties are intermix'd in a Bed, they make a goodly Shew: The Seeds of theſe ſhould be ſown in Autumn, ſoon after they are ripe; for thoſe ſown in the Spring do not grow near ſo large, nor will their Flowers be ſo double. When the Plants come up, they ſhould be either tranſplanted out, or ſome of them pull'd up: So that the remaining Plants may be left eight or ten Inches Diſtance each Way; whereby they will have Room to grow, and ſpread their Branches, which they generally produce in great Plenty, and their Flowers will be produced in larger Bunches. They will require no farther Care, but to keep them clear from Weeds. In *June* theſe Plants will flower; and their Seeds will ripen about the Beginning of *Auguſt*. But in order to have your Flowers more beautiful, you ſhould mark ſuch only for Seeds as produced very double and finely-variegated Flowers, pulling up or cutting off all ſingle or plain-colour'd Flowers.

DENS CANIS, [this Plant is ſo call'd, becauſe the Root of it reſembles the Tooth of a Dog] Dog's-Tooth.

The *Characters* are;

It hath a fleſhy Root ſhaped like a Dog's Tooth; the Leaves are broad, and ſpread upon the Ground, and, in Appearance, like thoſe of the Round-leav'd Sowbread*: The Flower is naked, and produced ſingle upon each Stalk, each conſiſting of ſix Leaves, and ſhaped like a* Lily, *and hang downward: The Petals of this Flower are reflex'd: The Pointal of the Flower becomes a roundiſh Fruit, in which are contained many oblong Seeds.*

The *Species* are;

1. DENS CANIS *latiore rotundioreque folio, flore candido. C. B.* The broad round-leav'd Dog's-Tooth, with a white Flower.
2. DENS CANIS *latiore rotundioreque folio, flore ex purpura rubente, majore. C. B.* Broad round-leav'd Dog's-Tooth, with a large purpliſh red Flower.
3. DENS CANIS *anguſtiore longioreque folio, flore albo. C. B.* Long narrow-leav'd Dog's-Tooth, with a white Flower.
4. DENS CANIS *anguſtiore longioreque folio, flore ſuave-rubente. H. R. Par.* Long narrow-leav'd Dog's-Tooth, with a fine red Flower.

There are ſome other Varieties of this Plant in the curious Gardens abroad; but theſe here mention'd are all that I have yet ſeen in *England*: The two firſt mention'd are the moſt common with us; the other two being very rare at preſent, and only to be found in a few curious Gardens.

Theſe Plants are propagated by ſowing their Seeds, as alſo by Off-ſets from the old Roots: The Seaſon for ſowing theſe Seeds, and the Method of raiſing and managing the young Plants, being the ſame as directed for the *Narciſſus*, I ſhall refer the Reader thereto, to avoid Repetition.

The Off-ſets, which theſe Roots produce but ſparingly, ſhould be taken off at the Time when the old Roots are tranſplanted, which ſhould be when the green Leaves decay, which is commonly towards the latter End of *May*; but the Roots ſhould not be kept long above Ground, for then they are apt to ſhrivel and dry up, which, if this happens, they ſeldom recover again. Theſe Plants delight in a good freſh Soil, neither too light nor too heavy, but ſuch as is of a middling Nature, and not over-dung'd; and they ſhould have an Eaſt or Weſt Aſpect; for if they are planted in a very warm or an extreme cold Situation, they ſeldom thrive well. They produce their Flowers early in *March*, for which they are valued, as alſo for the Beauty of their green Leaves. If Seeds of the different Sorts are ſown, there may be ſome new Varieties obtain'd, which is well worth the Trial, where we have ſo few Species of an early beautiful Flower as of this.

DENS LEONIS, [i. e. *Lion's-Tooth*: This Plant is ſo call'd, becauſe it reſembles the Jaw-bone of a Lion ſet with Teeth: It is alſo call'd *Caput Monachi*, i. e. *Monk's-Head*; becauſe after the Flowers are fallen off, what remains reſembles a bald Head: It is the firſt Plant that by the Antients was deſcribed under the Title of *Taraxacon*: It is by the *French* call'd *Piſſentlits*, becauſe it provokes Urine] Dandelion.

The *Characters* are;

It agrees in all reſpects with the Hawk-weed, *but only in its having a ſingle naked Stalk with one Flower upon the Top, whereas the* Hawk-weeds *have branching Stalks: To which may be added, the Flowers are for the moſt part fiſtulous or pip'd.*

There are ſeveral Species of this Plant, which are preſerv'd in curious Botanick Gardens; but as they are Plants of no great Uſe, and withal are very troubleſome in a good Garden, if ſuffer'd to feed, ſo they are never propagated. We have three or four Varieties which grow wild in *England*; but the moſt common broad-leav'd Kind is what is uſed in Medicine. There are alſo ſome People very fond of it blanch'd in the Spring, like *Endive*: But whoever has a mind to have it for either Uſe, may be abundantly ſupplied in the Fields.

DENTARIA, Tooth-wort.

The *Characters* are;

It hath a Flower conſiſting of four Leaves, which expand in Form of a Croſs; out of whoſe Flower-Cup riſes the Pointal, which afterward becomes a Fruit or Pod, which is divided into two Cells, by an intermediate Partition, to which the Valves adhere on both Sides; and is furniſhed with roundiſh Seeds. To theſe Marks ſhould be added, the Valves, when ripe, twiſt up like a Screw, and diſcharge the Seeds with Violence; and the Roots are fleſhy, ſcaly, and cut in, as it were, with Teeth.

The *Species* are;

1. DENTARIA *heptaphyllos. C. B. P.* Seven-leav'd Tooth-wort.
2. DENTARIA *pentaphyllos, foliis mollioribus. C. B. P.* Five-leav'd Tooth-wort, with ſoft Leaves.
3. DENTARIA *pentaphyllos, foliis aſperis. C. B. P.* Five-leav'd Tooth-wort, with rough Leaves.
4. DENTARIA *heptaphyllos baccifera. C. B. P.* Seven-leav'd berry-bearing Tooth-wort.
5. DENTARIA *triphyllos. C. B. P.* Three-leav'd Tooth-wort.
6. DENTARIA *enneaphyllos, Montis Aurei. H. R. Par.* Nine-leav'd Tooth-wort of *Mount d'Or*.

Theſe Plants grow on the Mountains in *Italy*, and in the Woods of *Auſtria*: The firſt Sort is found wild in Woods in ſome Parts of *England*, but the other Sorts are very rare in the *Engliſh* Gardens. Theſe Plants are propagated by Seeds, or parting of their Roots; the Seeds ſhould be ſown in the Autumn, ſoon after they are ripe, in a light ſandy Soil, and a ſhady Situation; in the Spring the Plants may be taken up where they grow too cloſe, and tranſplanted out in the like Soil and Situation; where, after they have taken Root, they will require no farther Care, but to keep them clear from Weeds; the ſecond Year they will produce Flowers, and ſometimes will perfect their Seeds.

The beſt Seaſon for taking up the old Roots to tranſplant them, is at *Michaelmas*, when the Leaves are decayed; at which Time they may be parted to increaſe them. Theſe Plants are proper to plant in dry Wilderneſſes, under the Shade of Trees; for their natural Places of Growth are in Woods, and on the Sides of Banks, under cloſe Cover of Trees.

DENTILLARIA. *Vide* Fraxinella.

DEW, is by ſome defined to be a Meteor bred of a thin cold Vapour; or, compoſed of the Steams and Vapours of the Earth, which being exhaled by the Heat of the Sun, and kept ſuſpended during his Preſence, do, upon his Abſence, convene into Drops, and then fall down to the Earth again.

Others define it, a thin, light, inſenſible Miſt or Rain falling while the Sun is below the Horizon.

The Origin and Matter of *Dews*, is, without doubt, from Vapour and Exhalations of the Earth and Water raiſed by the Warmth of the Earth, *&c.*

There being many Vapours in the Air, tho' not always viſible, hence it comes to paſs, that even in clear Weather great *Dews* fall, eſpecially in Countries where it ſeldom rains: For when it happens that the ſcatter'd Vapours are collected and condenſed together, and forced downwards, they muſt needs fall and bedew the Plants and Graſs.

The thin Veſicles of which Vapours conſiſt, being once detach'd from their Bodies, keep riſing in the Air till they arrive at ſuch a Stage as is of the ſame ſpecifick Gravity with themſelves, when their Riſe is ſtopp'd: Now as it is the Warmth or Fire that dilates the Parts of Water, and forms thoſe Veſicles that are ſpecifically lighter than the Air, and are capable of aſcending therein; ſo when that Heat declines or is loſt, as by the Approach or Contiguity of any colder Body, the Veſicles condenſe and become heavier, and deſcend.

Therefore the Sun warming the Atmoſphere in the Daytime, by the continual Influx of his Rays, the Vapours being once raiſed, continue their Progreſs, not meeting with any Thing to increaſe their Gravity, till ſuch Time as they are got far beyond the Reach of the reflected Warmth of the Earth in the middle Region of the Atmoſphere, and there condenſe and form Clouds.

Tho' ſome ſay, it is diſputable whether *Dews* ever congregate ſo as to form Clouds, but only as they are elevated by the Sun; ſo that when that Power is gone, as it is after the Setting of the Sun, they immediately deſcend: and this is more obſervable in very warm Weather and very hot Climates.

The Time for the falling of the *Dew* is either before Sun-riſing, or after Sun-ſet: but that it may regularly fall at ſuch Times, it is neceſſary for the Air to be calm; for windy or ſtormy Weather hinders it; but when it is calm Weather, and gentle Breezes are felt from the Weſt about the Setting, and from the Eaſt about the Riſing of the Sun, it is probable, that by moderately cooling the Air, they collect the Vapours, and precipitate them; and becauſe the Morning Breezes are more general than the Evening ones, for this Reaſon the Evening *Dews* fall only here and there, but thoſe in the Morning ſeldom fail to be univerſal: Or, as it may be otherwiſe expreſs'd, when the Sun is got below the Horizon, the Atmoſphere cools the Vapours, which have in the preceding Day been raiſed by the Warmth of the Earth, and the Rays of the Sun being lodged there, as ſoon as they are got out of the Air, they begin to condenſe apace, and ſpend their Stock of Heat and Fire on the cold moiſt Air that they paſs through.

Hence it is, that *Dews* are more copious in the Spring than other Seaſons, there being a greater Stock of Vapour in Readineſs, by reaſon there has been but a ſmall Expence thereof during the Winter's Cold and Froſt than at other Times.

It is found by Experience, that the *Dews* are more copious in hotter Countries than in cold, as *Pliny* obſerves of the Summer Nights in *Africa*, which he calls *Roſcida Æſtate Noctes*; the Reaſon of which ſeems to be this, that in the Day-time the Heat of the Sun raiſes abundance of Vapours out of the Water; which Vapours are ſo extremely rarefied by the ſame Heat, that they are diſperſed far and wide; but the Cool of the Night brings them together, and condenſes them to that Degree, that they fall to the Ground, but not in ſuch large Drops as Rain does: but in colder Countries, where there are frequent Rains, and the Vapours are leſs rarefied, moſt of them come down in Rain, and but a ſmall Part turns to *Dew*. Beſides, in *Africa* there is a great Difference between the Heat of the Day and Night, particularly in Summer, for their Nights are long, and very cold; whereas in Northern Countries they are little colder than the Day, and much ſhorter than in Places nearer the Line.

Pliny likewiſe relates of *Egypt*, that it abounds in *Dews* throughout all the Heat of Summer; for the Air being there too hot to conſtipate the Vapours in the Day-time, they never gather into Clouds, and for that Reaſon they have no Rain. But it is known, in Climates where the Days are exceſſive hot, the Nights are remarkably cold, ſo that the Vapours that are raiſed after Sun-ſet are readily condenſed into *Dews*; or, perhaps, notable Coldneſs may be rather the Effect than the Cauſe of the Quantity of *Dews*; for much Vapour being raiſed by the great Heat of the Earth, and the Stock of Fire being ſpent on it in the Day-time, the Influx of ſuch a great Quantity of Moiſture muſt greatly chill the Air.

The Difference between *Dew* and *Rain* ſeems to be only this, that *Dew* falls at ſome particular Times, as aforeſaid, and in very ſmall Drops, ſo as to be ſeen when down, but ſcarce perceivable while it is falling; whereas *Rain* falls at any Time, and in groſſer Drops.

The Rev. Dr. *Hales*, in his Treatiſe of *Vegetable Staticks*, tells us, That in order to find out the Quantity of *Dew* that fell in the Night on the 15th of *Auguſt*, at 7. *p. M.* he took two glazed Earthen Pans, which were three Inches deep, and twelve Inches diameter in Surface; that he fill'd them with pretty moiſt Earth, taken from off the Surface of the Ground, and they increaſed in Weight by the Night's *Dew* 180 Grains; and decreaſed in Weight by the Evaporation of the Day 1 Ounce + 282 Grains.

He ſays likewiſe, he ſet theſe in other broader Pans, to prevent any Moiſture from the Earth from ſticking to the Bottom of them. He adds, that the moiſter the Earth is, the more *Dew* falls on it in a Night, and more than a double Quantity of *Dew* falls on a Surface of Water than there does on an equal Surface of moiſt Earth: The Evaporation of a Surface of Water in nine Hours Winter's dry Day, is $\frac{1}{21}$ of an Inch: the Evaporate of a Surface of Ice ſet in the Shade during a nine Hours Day, was $\frac{1}{31}$.

So here are 540 Grains more evaporated from the Earth every 24 Hours in Summer than fall in *Dew* in the Night; that is, in 21 Days near 26 Ounces from a circular Area of a Foot diameter; and Circles being as the Squares of their Diameters, 10 Pounds + 2 Ounces will in 21 Days be evaporated from the Hemiſphere of 30 Inches diameter, which the *Sun-flower*'s Root occupies; which, with the 29 Pounds drawn off by the Plant in the ſame Time, makes 39 Pounds, that is, 9 Pounds and $\frac{1}{4}$ out of every Cubick Foot of Earth, the Plants Roots occupying more than 4 Cubick Feet: but this is a much greater Degree of Dryneſs than the Surface of the Earth ever ſuffers for 15 Inches Depth, even in the drieſt Seaſons in this Country.

In a long dry Seaſon therefore, eſpecially within the *Tropicks*, we muſt have recourſe, for ſufficient Moiſture to keep Plants and Trees alive, to the moiſt *Strata* of Earth which lie next below that in which the Roots are.

Now moiſt Bodies always communicate of their Moiſture to more dry adjoining Bodies; but this ſlow Motion of the Aſcent of Moiſture is much accelerated by the Sun's Heat to conſiderable Depths in the Earth, as is probable, he ſays, from the twentieth Experiment in the ſaid Book.

Now 180 Grains of *Dew* falling in one Night on a Circle of a Foot Diameter = 113 ſquare Inches; theſe 180 Grains being equally ſpread on this Surface, its Depth will be $\frac{1}{159}$ Part of an Inch $= \frac{180}{113 \times 254}$. He adds, that he found the *Dew* in a Winter Night to be the $\frac{1}{90}$ Part of an Inch; ſo that if we allow 151 Nights for the Extent of the Summer *Dew*, it will in that Time ariſe to one Inch Depth: And reckoning the remaining 214 Nights for the Extent of the Winter's *Dew*, it will produce 2,39 Inches Depth; which makes the *Dew* of the whole Year amount to 3,39 Inches Depth.

And the Quantity which evaporated in a fair Summer's Day from the ſame Surface, being as 1 Ounce 282 Grains, gives $\frac{1}{40}$ Part of an Inch Depth for Evaporation, which is four times as much as fell at Night.

He ſays likewiſe, that he found by the ſame Means, the Evaporation of a Winter's Day to be nearly the ſame as in a Summer's Day; for the Earth being in Winter more ſaturate with Moiſture, that Exceſs of Moiſture anſwers to the exceſſive Heat in Summer.

Nic. Cruquius, N° 381, of the *Philoſophical Tranſactions*, found that 28 Inches Depth evaporated in a whole Year from Water, *i. e.* $\frac{1}{12}$ of an Inch each Day at a mean Rate: But the Earth in a Summer's Day evaporates $\frac{1}{40}$ of an Inch; ſo the Evaporation of a Surface of Water is to the Evaporation of a Surface of Earth in Summer as 10 : 3.

The Quantity of *Rain* and *Dew* that falls in a Year is at a Medium 22 Inches: The Quantity of the Earth's Evaporation in a Year is at leaſt $9 + \frac{1}{2}$ Inches; ſince that is the Rate at which it evaporates in a Summer's Day: From which $9 + \frac{1}{2}$ Inches is to be deducted 3,39 Inches for circulating daily *Dew*, there remains 6,2 Inches; which 6,2 Inches deducted from the Quantity of Rain that falls in a Year, there remains at leaſt 16 Inches Depth, to repleniſh the Earth with Moiſture for Vegetation, and to ſupply the Springs and Rivers.

Dr. *Hale* proceeds to inſtance, in the Caſe of a Hop-Ground which he gives in his ninth Experiment of his Book of *Vegetable Staticks*, that the Evaporation there found, from the Hops, conſider'd only for three Months, at $\frac{1}{101}$ Part of an Inch each Day, which will be $\frac{9}{10}$ of an Inch: But before it be allow'd 6,2 Inches to form the Surface of the Ground; which added to $\frac{9}{10}$, give 7,1 Inches; which is the utmoſt that can be evaporated from a Surface of Hop-Ground in a Year: So that of 22 Inches Depth of Rain, there remain 15 Inches to ſupply Springs, which are more or leſs exhauſted, according to the Dryneſs or Wetneſs of the Year.

Hence we find, that 22 Inches Depth of Rain in a Year, is ſufficient for all the Purpoſes of Nature in ſuch flat Countries as that about *Teddington* near *Hampton-Court*: But in the Hill Countries, as in *Lancaſhire*, there falls 42 Inches Depth of Rain-water: From which deducting 7 Inches for Evaporation, there remain 35 Inches Depth of Water for the Springs, beſides great Supplies from much more plentiful *Dews* than fall in plain Countries; which vaſt Stores ſeem ſo abundantly ſufficient to anſwer the great Quantity of Water, which is convey'd away by the Springs and Rivers from thoſe Hills, that we need not have Recourſe for Supplies to the great Abyſs, whoſe Surface at High Water is ſurmounted ſome Hundreds of Feet by thoſe vaſt Hills from whence the longeſt and greateſt Rivers take their Riſe.

DIAPENSIA. *Vide* Sanicula.

DICTAMNUS ALBUS. *Vide* Fraxinella.

DICTAMNUS, Dittany.

The *Characters* are;

The Flower-cup conſiſts of two Leaves; after that another athwart the former; and again, a third in like manner, until a ſcaly Head be thence form'd: Out of the Center of all theſe Scales grows a Flower, whoſe Creſt is erect, roundiſh, and bifid;

bifid; the Beard is divided into three Parts; theſe little Flowers come forth from leafy Scales after the manner of the Verticle Plants, in a long looſe Spike.

The *Species* are;

1. DICTAMNUS *Creticus. C. B.* Dittany of *Crete.*
2. DICTAMNUS *montis Sipyli, origani foliis. Flor. Bat.* Dittany from Mount *Sipylus*, with wild Marjoram Leaves.

The firſt of theſe Plants hath been renown'd for many Ages, upon the Account of its ſovereign Qualities in Medicine. This is generally brought over dry from the *Levant*, and is ſtill us'd in ſome of the grand Preparations.

This Plant, altho' a Native of a warmer Country than ours, yet is tolerably hardy, and will endure the Cold of our common Winters, if planted in the open Air, provided it is planted in a dry ſandy Soil: It may be propagated by planting Cuttings in any of the Summer Months; which muſt be ſhaded and water'd until they have taken Root: afterwards they may be either planted in Pots, or in a warm Border under a South Wall, where it will remain for ſeveral Years, unleſs deſtroy'd by violent hard Froſts; for which Reaſon 'tis adviſeable always to keep a Pot or two of this Plant under a Frame as a Reſerve, in caſe thoſe abroad ſhould be deſtroy'd. This Plant produces its Flowers in *June* and *July*, but the Seeds are ſeldom perfected in this Climate: And altho' there is no great Beauty in the Flowers of this Plant, yet for the Variety of its round hoary ſweet-ſmelling Leaves, it deſerves a Place in very good Gardens.

The ſecond Sort was found upon Mount *Sipylus*, by Sir *George Wheeler* in his Travels, and by him ſent to *Oxford*. This is a very neat Plant, affording long Spikes of Flowers which continue a long time in Beauty, and deſerves a Place with the former in every good Garden. This is propagated and manag'd as the other in every reſpect.

DIERVILLA. [*This Plant was ſo named by Dr.* Tournefort, *from Mr.* DIERVILLE *a Surgeon, who brought it from* ACADIA.] *We have no* Engliſh *Name for this Plant.*

The *Characters* are;

It hath a Flower conſiſting of one Leaf, which is tubulous, and divided into five Parts: The Ovary, which crowns the Pointal, is produced from the Centre of the Two-leav'd Calyx; and after the Flower is paſſed, it becomes a pyramidal Fruit divided into four Cells, which are filled with ſmall Seeds.

We have but one *Species* of this Plant at preſent in *Europe*, which is;

DIERVILLA *Acadienſis fruticoſa, flore luteo. Acad. Reg. Scien.* Shrubby Diervilla of *Acadia*, with a yellow Flower.

This is a very low Shrub, ſeldom riſing to the Height of three Feet in *England*; but is very ſubject to ſpread at the Root, and become buſhy. The Flowers are ſmall, and produced ſparſedly on the Branches, ſo that it doth not make any good Appearance in a Garden; but as it is pretty hardy, ſo it may be admitted as an Under-ſhrub, to fill up Vacancies in Wilderneſs Quarters, where it will add to the Variety. It is eaſily propagated from Suckers, which it generally produces in great Plenty from the Root, or by laying down the Branches. It requires a Soil not too hot and dry, nor over wet, but of a middling Nature.

DIGITALIS; [This Plant is ſo call'd, becauſe the Flower of it reſembles a Finger-ſtall.] Fox-Glove.

The *Characters* are;

The Leaves are produc'd alternately on the Branches; the Cup of the Flower conſiſts of one Leaf, which is divided into ſix ample long Segments; the Flower conſiſts of one Leaf, is tubuloſe and compreſs'd, and a little reflex'd at the Brim; theſe Flowers are diſpos'd in a long Spike, and always grow upon one Side of the Stalk; the Ovary of the Flower becomes a roundiſh Fruit, which ends in a Point, and opens in the Middle; has two Cells, in which are contain'd many ſmall Seeds.

The *Species* are;

1. DIGITALIS *purpurea. J. B.* The purple Fox-Glove.
2. DIGITALIS *vulgaris, flore carneo. Hort. Edinb.* Common Fleſh-colour'd Fox-Glove.
3. DIGITALIS, *flore magno candido. J. B.* Fox-Glove, with a large white Flower.
4. DIGITALIS *latifolia, flore ferrugineo. Mor. Hiſt.* Broad-leav'd Fox-Glove, with an Iron-colour'd Flower.
5. DIGITALIS *anguſtifolia, flore ferrugineo. C. B.* Narrow-leav'd Fox-Glove, with an Iron-colour'd Flower.
6. DIGITALIS *lutea, magno flore. C. B.* Fox-Glove, with a large yellow Flower.
7. DIGITALIS *major lutea vel pallida, parvo flore. C. B.* Greater Fox-Glove, with a ſmall pale-yellow Flower.
8. DIGITALIS *Orientalis, folio Tragopogi, flore albido. T. Cor.* Eaſtern Fox-Glove, with a Goat's-Beard Leaf, and a whitiſh Flower.
9. DIGITALIS *Canarienſis acanthoides fruteſcens, flore aureo. Hort. Amſt.* Shrubby *Canary* Fox-Glove, with a Gold-colour Flower.

The firſt of theſe Plants is very common in ſhady Woods, and upon uncultivated Heaths in divers Parts of *England*: The two next are alſo Varieties of the firſt, from which they only differ in the Colour of the Flowers.

The fourth, fifth, and ſixth Sorts, are preſerv'd in Gardens, for the Beauty of their Flowers; but the ſeventh and eighth Sorts are only cultivated in Botanick Gardens for the ſake of Variety, as being Plants of no great Beauty.

Theſe Plants may all be propagated by ſowing their Seeds in *March*, in a freſh Soil that is not too ſtiff; and when the Plants come up, they ſhould be tranſplanted into Beds ſix Inches aſunder, where they may remain until the *Michaelmas* following, obſerving to keep them clear from Weeds; then you may tranſplant them into the middle of large Borders, intermixing the Variety of Colours at regular Diſtances amongſt Flowers of the ſame Growth. In *May* following theſe will produce their Flowers, which will continue near a Month in Beauty, if the Seaſon is not too hot and dry, and in *Auguſt* the Seeds will ripen; which if permitted to fall to the Ground, will come up in great Plenty, and abundantly ſtock the Garden with Plants.

Some of theſe Sorts ſeldom remain above two Years, when after having perfected their Seeds, they die, unleſs Care be taken to cut off the Flowers when they are in Beauty, before they begin to decay, which often cauſes the Roots to break out again, whereby they may be kept for ſeveral Years, (eſpecially the Iron-colour'd Sorts) and may be increas'd by parting their Roots.

Theſe Plants thrive beſt in a poor undung'd freſh Soil, nor can they be maintain'd many Years in a rich Soil, and their Flowers will be, when planted therein, much ſmaller, and of ſhorter Duration; and altho' they are ſome of them common in *England*, yet they make a very good Appearance in large Gardens.

The ninth Sort is of a nicer Nature, and requires to be ſhelter'd in a Green-houſe in Winter; which indeed it is worthy of, for it is one of the handſomeſt Flowers, when in Beauty, of moſt of the Green-houſe Plants: This is multiply'd by ſowing the Seeds in the Spring upon a moderate Hot-bed, and when the Plants are ſtrong enough to be remov'd, they ſhould be planted in Pots fill'd with freſh light ſandy Earth, and the Pots plung'd into a very moderate Hot-bed, in order to facilitate the Rooting of the Plants, obſerving to water and ſhade them until they have taken freſh Root; after which they muſt be enur'd to the open Air by Degrees, and in Summer may be expos'd in a ſhelter'd Place amongſt other Exotick Plants: In Winter the Pots ſhould be plac'd in a Green-houſe, ſo that the Plants may enjoy as much free Air as poſſible, but muſt be preſerv'd from Froſt, and do require frequent Refreſhings with Water.

This Plant produces its Flowers in *June*, and the Seeds ripen in *Auguſt*.

DILL. *Vide* Anethum.

DIOSCOREA. [*This Plant was ſo named by Father* Plumier, *from* PEDACIUS DIOSCORIDIS, *a famous Phyſician.*] *We have no* Engliſh *Name for this Plant.*

The *Characters* are;

It hath a ſpreading bell-ſhap'd Flower, conſiſting of one Leaf, which is divided at the Extremity into ſeveral Parts; from whoſe Cup ariſes the Pointal, which afterwards becomes a triangular Fruit, divided into three Cells; in which are contained orbicular Seeds, which are bordered.

The *Species* are;

1. DIOSCOREA *ſcandens, foliis tamni, fructu racemoſo. Plum. Nov. Gen.* Climbing Dioſcorea, with Black-briony Leaves, and the Fruit growing in Cluſters.
2. DIOSCOREA *ſcandens, folio haſtato, fructu racemoſo. Houſt.* Climbing Dioſcorea, with a ſpear-ſhap'd Leaf, and cluſtered Fruit.
3. DIOSCOREA *ſcandens, folio ſubrotundo acuminato, fructu racemoſo. Houſt.* Climbing Dioſcorea, with a roundiſh Leaf ending in a Point, and cluſtered Fruit.

Theſe Plants, all of them, grow wild in *America*; the firſt and third Sorts were found in great Plenty in the woody Parts of *Jamaica*, by the late Dr. *Houſtoun*; but the ſecond Sort he found at *Carthagena*, from whence he ſent Seeds of this Plant to *England*. They generally grow under Trees or Hedges, and twiſt up the Stems of whatever Plants grow near them.

In *Europe* theſe Plants are preſerved in ſome curious botanic Gardens, for Variety; but they have no great Beauty, ſo are ſeldom admitted into other Gardens. They may be propagated by ſowing of their Seeds on a Hot-bed early in the Spring; and when the Plants are come up, they ſhould be each tranſplanted into a ſmall Pot, filled with light freſh Earth, and plunged into a Hot-bed of Tanners-bark, obſerving to water and ſhade them until they have taken new Root; after which time, they ſhould have a large Share of freſh Air admitted to them in warm Weather, and muſt be frequently watered. In this Bed the Plants may remain till Autumn, when they ſhould be removed into the Bark-ſtove, and plunged into the Tan, under the other Plants; for theſe die to the Root every Winter, and riſe again in the Spring; ſo that the Roots muſt not be over watered, when the Plant is quite decayed to the Ground. Theſe Roots will abide ſeveral Years, provided they are thus managed, and in three Years after ſowing will flower in *England*.

DIPSACUS, [διψακὸς, *Gr.* i. e. *thirſty*. It is ſaid to have taken its Name by way of contrary, becauſe it receives the Dew or Rain in the hollow *Sinus* of its Leaves that cohere together, by which it drives away the Injuries of Thirſt. It is alſo call *Labrum Veneris*, from the Poſition of its Leaves, which form a Sort of Baſon which contains a Liquor that beautifies the Face] The Teaſel.

The *Characters* are;

The whole Flower hath no proper Calyx, but Leaves repreſenting the Perianthium encompaſſing the Bottom of the Head; the little Flowers, which are produc'd ſingly from between the Scales, are collected into a Head ſomewhat like a Bee-hive; theſe are ſucceeded by longiſh four-corner'd Seeds.

The *Species* are;

1. DIPSACUS *ſylveſtris, aut virga paſtoris major. C. B.* The Greater Wild Teaſel.
2. DIPSACUS *ſylveſtris, capitulo minore, vel virga paſtoris minor. C. B.* Small Wild-Teaſel or Shepherd's Rod.
3. DIPSACUS *folio laciniato. C. B.* Cut-leav'd Teaſel.
4. DIPSACUS *ſativus. C. B.* Manured Teaſel.

The firſt of theſe Plants is very common upon dry Banks in moſt Parts of *England*, and is ſeldom cultivated in Gardens, unleſs for the ſake of Variety.

The ſecond is alſo found wild in many Parts of *England*, tho' leſs common than the firſt.

The third is a Variety, which differs from the firſt, in having the Leaves deeply cut or jagged.

But it is the fourth Sort only which is cultivated for Uſe, which is call'd *Carduus Fullorum*, or *Fullonum*, being of ſingular Uſe in raiſing the Nap upon Woollen Cloth; for which Purpoſe there are great Quantities of this Plant cultivated in the Weſt Country.

This Plant is propagated by ſowing the Seed in *March*, upon a Soil that has been well dry'd: About one Peck of this Seed will ſow an Acre; for the Plants ſhould have Room to grow, otherwiſe the Heads will not be ſo large, nor in ſo great Quantity. When the Plants are come up, you muſt hough them in the ſame Manner as is practis'd for *Turnips*, cutting down all the Weeds, and ſingling out the Plants to about ſix or eight Inches Diſtance; and as the Plants advance, and the Weeds begin to grow again, you muſt hough them a ſecond Time, cutting out the Plants to a wider Diſtance; for they ſhould be at laſt left at leaſt a Foot aſunder: And you ſhould be particularly careful to clear them from Weeds, eſpecially the firſt Summer; for when the Plants have ſpread ſo as to cover the Surface of the Ground, the Weeds will not ſo readily grow between them. The ſecond Year after Sowing, the Plants will ſhoot up to Heads, which will be fit to cut about the Beginning of *Auguſt*, at which Time they ſhould be cut, and ty'd up in Bunches, ſetting them in the Sun, if the Weather be fair, but if not, they muſt be ſet in Rooms to dry them. The common Produce is about an hundred and ſixty Bundles or Staves upon an Acre, which they ſell for about one Shilling a Stave. Some People ſow *Caraway* and other Seeds amongſt their *Teaſels*: But this not a good Method, for the one ſpoils the other; nor can you ſo eaſily clear them from Weeds, as when alone.

DITTANY. *Vide* Dictamnus.

DOCK. *Vide* Lapathum.

DODARTIA. [*This Plant was ſo named by Dr.* Tournefort, *from Monſieur* DODART, *a Member of the Academy of Sciences at* Paris.] *We have no* Engliſh *Name for this Plant.*

The *Characters* are;

It hath a perſonated tubulous Flower, conſiſting of one Leaf, having two diſtinct Lips; the upper Lip is bifid, and the under one is divided into three Parts; from whoſe Calyx ariſes the Pointal, fixed like a Nail in the hinder Part of the Flower, and afterwards becomes a roundiſh Fruit, divided into two Cells, which are filled with ſmall Seeds.

The *Species* are;

1. DODARTIA *orientalis, flore purpuraſcente. Tourn. Cor. Eaſtern* Dodartia, with a purpliſh Flower.
2. DODARTIA *bellidis folio, flore albo ſpicato.* Dodartia with a Daiſy-leaf, and white Flowers growing in a Spike.

Theſe Plants may be propagated by ſowing their Seeds on a Bed of freſh Earth in the Spring; and when the Plants are come up an Inch high, they ſhould be tranſplanted, ſome into ſmall Pots, and the others into warm Borders (for they require ſome Protection in Winter): thoſe which are planted in Pots, ſhould be placed under a Hot-bed Frame in Winter, where they may be covered in froſty Weather; but in mild Weather they ſhould have as much free Air as poſſible, otherwiſe they will draw up very weak, and their Stems will rot off at Bottom in the Spring. The ſecond Year after ſowing, theſe Plants will flower, and ripen their Seeds, and very often decay ſoon after; though, if the Plants are very ſound, they will ſometimes remain three or four Years.

DOG'S TOOTH. *Vide* Dens Canis.

DOG-WOOD. *Vide* Cornus.

DORIA.

The *Characters* are;

It hath a perennial fibroſe Root; the Leaves are almoſt whole, and oblong; the Cup of the Flower is cylindrical, and in Form of a Tube; The Flowers grow upon the Summits of the Branches, and are diſpos'd either in Form of an Umbel, or in a looſe Panicle, which are radiated like the Ragwort.

The *Species* are;

1. DORIA *Narbonnenſium. Hort. Eyſt.* The *Narbonne* Doria.
2. DORIA *quæ Jacobæa, foliis integris & mucronatis. Mor. Hiſt.* Doria with whole ſharp-pointed Leaves.
3. DORIA *quæ Jacobæa Orientalis, limonii folio. T. Cor.* Eaſtern Doria, with a Sea-Lavender Leaf.
4. DORIA *Americana, lato rigido folio. Boerh. Ind. American* Doria, with a broad ſtiff Leaf.
5. DORIA *Africana arboreſcens, craſſis & ſucculentis foliis, atriplicem referentibus. Boerh. Ind. African* Tree Doria, with thick ſucculent Leaves, ſomewhat like thoſe of *Atriplex*.
6. DORIA *quæ Jacobæa Africana, hederæ terreſtris folio repens. Hort. Amſt. African* creeping Doria, with a Ground-Ivy Leaf.
7. DORIA *quæ Jacobæa Africana fruteſcens, coronopi folio. Hort. Amſt. African* ſhrubby Doria, with a Hart's-horn Leaf.
8. DORIA *quæ Jacobæa Africana fruteſcens, craſſis & ſucculentis foliis. Hort. Amſt. African* ſhrubby Doria, with thick ſucculent Leaves.

The four firſt Sorts are very hardy, and will endure in the open Air; theſe may be propagated by parting of their Roots either in Spring or Autumn, and will grow in almoſt any Soil or Situation, but are too large and rambling for a ſmall Flower-Garden, eſpecially the firſt Sort, which creeps greatly at the Root, and will over-run a large Spot of Ground in one Year; theſe are ſeldom preſerved except in Botanick Gardens for Variety.

The other four Sorts are beautiful Flowering Plants, and well worth propagating in every good Garden: Theſe are increas'd by planting Cuttings of any of the Kinds during the Summer Months, in a Bed of light, rich Earth, obſerving to water and ſhade them until they have taken Root: Then you muſt carefully tranſplant them into Pots fill'd with the like rich light Earth, ſetting them in the Shade until they have taken

Root ; after which, they may be expos'd with *Geraniums*, &c. until *October*, when they muſt be remov'd into the Green-houſe, where they ſhould be plac'd as near the Glaſſes as poſſible, that they may have free Air whenever the Weather will permit, and muſt have frequent Refreſhings with Water. Theſe Plants produce their Flowers towards the latter End of Summer, and continue moſt Part of the Autumn in Beauty, but ſeldom produce good Seeds with us.

DORONICUM: [Some derive it of Δῶρον, a *Gift*, or *Palm*, and Νίκη, *Victory*, q. d. a *Triumphant Crown* ; but others will have it deriv'd from an *Arabick* Word] Leopards-Bane.

The *Characters* are ;

It hath an intricate knotted Root ; the Leaves are produc'd alternately on the Branches ; the Stalks are a little branch'd ; the Flowers (which grow on the Tops of the Stalks) are radiated like the Greater Starwort ; *the Half-Florets in the Disk of the Flower are trifid : The Cup of the Flower is expanded, and cut into many Parts almoſt to the Bottom, and is not ſcalely, but each ſingle Segment is in the Form of a Diſh.*

The *Species* are ;

1. Doronicum *radice Scorpii. C. B.* Scorpion-rooted Leopards-Bane.
2. Doronicum *plantaginis folio. C. B.* Plantain-leav'd Leopards-Bane.
3. Doronicum *plantaginis folio, alterum. C. B.* Another Plantain-leav'd Leopards-Bane.
4. Doronicum *plantaginis folio, hirſutum. Vaill.* Rough Plantain-leav'd Leopards-Bane.

The firſt of theſe Plants is ſometimes us'd in Medicine with us, as is the third Sort in *Germany* : Theſe are all Plants of no great Beauty ; but as they will thrive in almoſt any Soil or Situation, ſo they may be allow'd a Place in a ſhady Border, for Variety-ſake. They all increaſe abundantly by their ſpreading Roots, which may be parted either in Spring or Autumn ; as alſo by Seeds, which ſhould be ſown ſoon after they are ripe. They produce their Flowers for ſeveral Months in the Summer, as in *May*, *June*, *July*, and *Auguſt*, and their Seeds ripen ſoon after.

DORSIFEROUS PLANTS, [of *Dorſum* the *Back*, and *fero*, Lat. *to bear*] ſuch Plants as are of the Capillary Kind, without Stalk, and that bear their Seeds on the Back-ſide of their Leaves.

DORSTENIA. [*This Plant was ſo named by Father* Plumier, *from Dr.* Dorſten, *a* German *Phyſician, who publiſhed a Hiſtory of Plants in Folio*] Contrayerva.

The *Characters* are ;

It hath a thick fleſhy Placenta, which is flat, and ſituated vertically ; upon which are placed many apetalous Flowers, which are ſucceeded by roundiſh Seeds, ſomewhat like thoſe of Gromewell.

The *Species* are ;

1. Dorstenia *dentariæ radice, ſphondylii folio, placenta ovali. Houſt.* Contrayerva, with a Tooth-wort Root, Cow-parſnip Leaf, and an oval Placenta.
2. Dorstenia *dentariæ radice, folio minus laciniato, placenta quadrangulari & undulata. Houſt.* Contrayerva, with a Tooth-wort Root, leſs jagged Leaf, and a quadrangular undulated Placenta.
3. Dorstenia *ſphondylii folio ſerrato, placenta quadrangulari, radice dentariæ.* Contrayerva, with a Tooth-wort Root, ſawed Cow-parſnip Leaf, and a quadrangular Placenta.

The firſt of theſe Plants was diſcovered by my late ingenious Friend Dr. *William Houſtoun*, near *Old Vera Cruz* in *New Spain*. The ſecond was found by the ſame Gentleman, on the rocky Grounds about *Campeachy*. The third Sort was found in great Plenty in the Iſland of *Tobago*, by Mr. *Robert Millar*, Surgeon. But the Roots of all theſe Species are indifferently brought over and uſed in Medicine, and for Dying.

Theſe Plants are at preſent very rare in *Europe*, nor was it known what the Plant was whoſe Roots were imported, and had been long uſed in Medicine in *England*, until the late Dr. *Houſtoun* informed us ; for altho' Father *Plumier* had diſcovered one Species of this Plant, and given the Name of *Dorſtenia* to the Genus, yet he ſeems not to have known, that the *Contrayerva* was the Root of that Plant.

It will be difficult to obtain theſe Plants, becauſe the Seeds are ſeldom to be found good ; nor will they grow if they are kept long out of the Ground ; ſo that the only ſure Method to obtain them, is to have the Roots taken up at the Time when their Leaves begin to decay, and planted pretty cloſe in Boxes of Earth, which may be brought very ſafe to *England* ; provided they are preſerved from Salt-water, and are not over-watered with freſh Water in their Paſſage ; when the Plants arrive they ſhould be tranſplanted each into a ſeparate Pot, filled with freſh Earth, and plunged into the Bark-ſtove, which ſhould be kept to a moderate Heat, and the Plants muſt be frequently refreſhed with Water during the Summer Seaſon, but in Winter, when the Leaves are decayed, it ſhould be given to them more ſparingly : With this Management theſe Plants may not only be maintained, but may be alſo increaſed by parting their Roots in the Spring, before the Plants put out their Leaves.

DORYCNIUM, [Δορύκνιον, of Δόρυ, Gr. a *Spear*] Shrub Trefoil.

The *Characters* are ;

It hath papilionaceous Flowers, which are ſucceeded by ſhort Pods, in each of which is contain'd one ſingle Seed ; to which may be added, the Leaves are ſingle, and divided to the Bottom into five Segments.

We have but one *Species* of this Plant in *England*, which is ;

Dorycnium *Monſpeſulanum fruticoſum. J. B.* Shrub Trefoil of *Montpelier*.

This Shrub riſes with us to the Height of five or ſix Feet, and produces Cluſters of ſmall Flowers at the Extremity of the ſlender Branches, which are ſucceeded by ſhort Pods of Seeds. There is very little Beauty in this Plant, but it is preſerv'd in Botanick Gardens for Variety. It may be propagated by ſowing the Seeds in the Spring, either on a moderate Hot-bed, or on a warm Border under a Wall, where they will riſe very well, and may be afterwards tranſplanted into Pots, to be ſhelter'd in Winter ; or if planted in a warm Border and a dry Soil, will endure our common Winters very well in the open Air.

DOUGLASSIA.

This Plant was ſo named by the late Dr. William Houſtoun, *in Honour to Dr.* James Douglaſs, *an eminent Phyſician at* London.

The *Characters* are ;

It hath an anomalous Flower, conſiſting of one Leaf, whoſe lower Part is tubulous, but the upper Part is expanded, and divided into five Segments ; the Fruit, which is roundiſh, is divided into two Parts, which contain two Seeds.

There is but one *Sort* of this Plant at preſent known, viz.

1. Douglassia *frutescens & ſpinoſa, liguſtri folio, flore albo. Houſt. Paliuro affinis liguſtrifolia ſpinoſa, flore monopetalo difformi, fructu ſicco ſubrotundo. Sloan. Cat. Jam.* Shrubby prickly Douglaſſia, with a privet Leaf, and a white Flower.

This Shrub grows in great Plenty in the Woods and Savannas in *Jamaica* and *Barbadoes* ; where it riſes to the Height of ten or twelve Feet, and ſpreads into many Branches, at the Extremity whereof there are ſent forth Cluſters of white Flowers which are ſucceeded by roundiſh Fruit.

It may be propagated by Seeds, which muſt be obtained from the Countries of its Growth, for it doth not produce Seeds in this Country : This Seed muſt be ſown in Pots filled with light rich Earth, and then plunged into a Hot-bed of Tanners-bark, obſerving to water the Pots frequently to keep the Earth moiſt, otherwiſe the Seeds will not vegetate ; in about a Month after ſowing (if the Seeds are freſh) the Plants will appear above Ground, when they muſt be carefully watered three Times a Week, provided the Bed is warm ; and in the Day-time, when the Sun is warm, the Glaſſes of the Hot-bed ſhould be raiſed a little with Stones, to admit freſh Air to the Plants, as alſo to give Vent for the Steam of the Bed to paſs off : With this Management the Plants will be fit to tranſplant in about three Weeks or a Month's Time after their Appearance above Ground ; when they ſhould be carefully ſhaken out of the Pots, and ſeparated, being cautious how you part their Fibres, not to tear them ; then plant each into a ſeparate ſmall Pot filled with light rich Earth, and plunged into the Hot-bed again, being careful to ſhade the Plants until they have taken Root ; after which Time they muſt be duly watered, and the Glaſſes of the Hot-bed muſt be raiſed every Day, in proportion to the Warmth of the Seaſon, to admit freſh Air to the Plants, that they may increaſe in Strength, in proportion to their growing in Height. Theſe Plants may remain in the Hot-bed until *Michaelmas* (provided there is Room for them to ſtand without touching of the Glaſſes); then the Plants ſhould be removed into the Stove, and plunged into the Bark-bed, for the Winter Seaſon. In the Winter theſe Plants muſt be frequently watered, but there ſhould not be too much given to them at each Time; but in Summer they will require to be more plentifully watered. Theſe Plants being Natives of warm Countries, will not thrive, if they are expoſed to the open Air in this Country; ſo that they ſhould be conſtantly kept in the Stove, being careful to give them a large Share of Air in Summer, when the Weather is warm. With this Management the Plants will make good Progreſs; and in two or three Years will begin to produce their Flowers, and will continue ſeveral Years to flower; but they never produce ripe Seeds in this Country. This Plant continues green throughout the Year, ſo will afford an agreeable Variety in the Stove, among other tender exotic Plants of the ſame Country.

DRACOCEPHALON, of δράκων, a Dragon, and κεφαλὴ, a Head, *i. e.* Dragon's-head.

The *Characters* are;

It hath a labiated Flower conſiſting of one Leaf, whoſe upper Lip, which is Creſted, and its under Lip, which is divided into three Segments, end in Chops or Jaws, and have the Repreſentation of a Dragon's-Head: Out of the Flower-cup riſes the Pointal, fixed like a Nail in the hinder Part of the Flower; and is accompanied by four Embryos, which become ſo many Seeds, ſhut up in the Flower-cup.

There is but one *Species* of this Plant, *viz.*

Dracocephalon *Americanum. Breyn. prod. American* Dragon's-head.

This Plant hath been ranged amongſt the Foxgloves by ſeveral botanic Writers; but tho', from the Shape of the Flower, it ſeems to have ſome Affinity to that Genus; yet by the Flowers growing in Whorles round the Stalks, and each Flower being ſucceeded by four naked Seeds, it plainly belongs to the verticillate Tribe. This is propagated by parting of the Roots in the Spring (for it ſeldom produces good Seeds in *England*); theſe ſhould be planted in Pots, filled with freſh rich Earth, and during the Summer Seaſon they ſhould be expoſed in a Place where they may be ſheltered from ſtrong Winds; and they muſt be conſtantly watered in dry Weather, otherwiſe they will not flower ſtrong. In *July* theſe Plants will produce long Spikes of beautiful purple Flowers, and ſometimes in a good Seaſon they will produce Seeds. In Autumn theſe Plants die to the Ground, when the Pots ſhould be placed under a Hot-bed Frame, where they may be ſheltered from ſevere Froſt in Winter; but in mild Weather they ſhould have as much free Air as poſſible. In *March* theſe Plants may be taken out of the Frame, when they ſhould be new potted, and the Roots parted, to increaſe them; but this ſhould be done before the Plants begin to ſhoot up.

DRACO HERBA, [i. e. *Dragons-wort*] Tarragon, *vulgo.*

The *Characters* are;

The Leaves, which are like thoſe of Hyſſop, *are produc'd alternately on the Branches; the Lower being divided, and the Upper ones are whole; the Flowers are ſmall, diſcous, and diſpos'd into a long Spike.*

There is but one *Species* of this Plant, which is,

Draco-Herba. *Dod.* Herb-Dragon or Tarragon.

This Plant was formerly in great Eſteem for Sallads and Soops, but at preſent it is not ſo much us'd: It propagates it ſelf faſt enough by its creeping Roots, which in a ſhort Time will ſpread very far; or it may be increas'd by planting Cuttings or Slips in the Spring of the Year; which, if kept ſupply'd with Water, will take Root in a ſhort Time. This Plant will grow in almoſt any Soil or Situation, but beſt in that which is light and moiſt.

DRACO ARBOR. *Vide* Palma.

DRACUNCULUS; [*q. d.* Little Dragon] Dragon.

The *Characters* are;

The Leaves are like thoſe of Arum, *but are divided into many Parts; the Stalk is ſpotted, but in other reſpects it agrees with the* Arum.

The *Species* are;

1. Dracunculus *polyphillus. C. B.* Many-leav'd Dragon.

2. Dracunculus *polyphyllus, foliis ex luteo variegatis. H. R. Par.* The yellow ſtrip'd-leav'd Dragon.

3. Dracunculus *polyphyllus, foliis ex albo variegatis.* The white ſtrip'd-leav'd Dragon.

4. Dracunculus *Canadenſis triphyllus pumilus. Tourn.* Dwarf *Canady* Dragon, with three Leaves.

5. Dracunculus *Indicus, folio trifido. Tourn. Indian* Dragon, with a trifid Leaf.

6. Dracunculus *Indicus, folio quinquifido. Tourn. Indian* Dragon, with a quinquifid Leaf.

7. Dracunculus *Americanus, colocaſiæ foliis laciniatis. Tourn. American* Dragon, with a jagged Colocaſia Leaf.

8. Dracunculus *Americanus ſcandens, triphyllus & auritus. Tourn.* Climbing *American* Dragon with three Leaves, which have Ears to them.

9. Dracunculus *polyphyllus major Indicus ſerotinus, immaculato caule. Tourn.* Greater many-leav'd late *Indian* Dragon, with an unſpotted Stalk.

10. Dracunculus *Zeylanicus polyphyllus, caule aſpero ex flavo & viridi variegato. Tourn.* Many-leav'd Dragon of *Ceylon*, with a rough Stalk, variegated with Yellow and Green.

11. Dracunculus *Zeylanicus ſpinoſus, polypodii foliis, radice repente. Tourn.* Prickly Dragon of *Ceylon*, with polypody Leaves, and a creeping Root.

12. Dracunculus *Americanus, caule aſpero puniceo, radice cyclaminis. Tourn. American* Dragon, with a rough ſcarlet Stalk, and a Root like that of Sowbread.

13. Dracunculus *Americanus ſcandens. Tourn.* Climbing *American* Dragon.

14. Dracunculus *Zeylanicus polyphyllus, caule aſpero vireſcente, maculis albicantibus notato. Tourn.* Many-leav'd Dragon of *Ceylon*, with a rough green Stalk, mark'd with whitiſh Spots.

The firſt of theſe Sorts is cultivated in Gardens for medicinal Uſes; the ſecond and third are Varieties of the firſt, which are preſerv'd in curious Gardens of Plants. Theſe, tho' they are Plants of no great Beauty, yet for the ſurpriſing Oddneſs of their Flowers, together with their ſpotted Stalks, do deſerve a Place in ſome remote Corner of the Garden.

They are propagated by their knobby Roots, which, if ſuffer'd to remain two or three Years undiſturb'd, will afford many Off-ſets. The beſt Seaſon for tranſplanting theſe Roots is in Autumn, ſoon after the green Leaves decay; for if they are remov'd after they have taken freſh Root, and began to ſhoot, they ſeldom produce Flowers the ſucceeding Summer; or if they do, they are very weak: Theſe will thrive almoſt in any Soil and Situation, but beſt in an open Expoſure, and a light Soil.

The fifth and following Sorts of *Dragon* are very tender Plants, ſo will not live in this Country, unleſs they are preſerved in the warmeſt Stoves: The ſeveral *American* Sorts grow naturally in the Woods in *Jamaica*, and other hot Parts of *America*: The climbing Sorts twiſt themſelves round the Trunks of Trees, into which they faſten their Roots, which are ſent forth from their Joints; and riſe to the Height of thirty or forty Feet. Theſe climbing Sorts are eaſily propagated by Cuttings, which being very ſucculent, may be brought over to *England* in a Box of dry Hay, if they are packed up ſeparate, ſo as not to injure each other by the Moiſture, which is apt to flow out at the Part where they are cut off; which may occaſion a Fermentation, and thereby rot the Cuttings. When the Cuttings arrive, they ſhould be planted in ſmall Pots, filled with light freſh Earth, and plunged into a Hot-bed of Tanners-bark; being very careful not to let them have too much Moiſture until they have taken Root, leſt it rot them: When they have taken Root, they muſt be frequently refreſhed with Water, but it muſt not be given to them in large Quantities; when the Weather is warm, the Glaſſes of the Hot-bed ſhould be raiſed every Day, to admit freſh Air to the Plants; and when they are grown pretty large, they ſhould be placed in the Bark-bed in the Stove, where they muſt be placed near ſome ſtrong Plants, to which they may faſten themſelves, otherwiſe they will not thrive; for tho' they will ſend forth Roots at their Joints, which will faſten to the Mortar of the Stove, when placed againſt the Wall; yet they will not thrive near ſo well as againſt a ſtrong Plant, which will afford them Nouriſhment.

The other Sorts are propagated by Off-ſets from their Roots; theſe may be procured from the Countries of their Growth, and ſhould be planted in Tubs of Earth about a Month before they are put on board the Ship to tranſport them. Theſe Tubs ſhould be placed in a ſhady Situation, until they have taken Root; but they ſhould not have much Water given to them, leſt it rot them. In their Paſſage, great Care ſhould be had to keep them from Salt-water, as alſo not to let them have too much Water given them; for if they have a little Water once or twice a Week at moſt, while they are in a hot Climate, and when they come into a cooler Climate, once in a Fortnight will be ſufficient to water them; and this ſhould be done ſparingly, leſt it rot them: for if the Tops of the Plants ſhould decay in their Paſſage, if the Roots are not rotted, they will ſoon recover with proper Care.

When the Plants arrive, they ſhould be tranſplanted into Pots, filled with light freſh Earth, and plunged into a Hot-bed of Tanners-bark, and gently watered, until they have taken good Root; after which Time they will require to be frequently refreſhed with Water; but as their Stems are very ſucculent, ſo they muſt not have too much Moiſture, for that will rot them. Theſe Plants ſhould be conſtantly kept in the Stove, where in hot Weather they ſhould have freſh Air admitted to them; but in Winter they muſt be kept very warm, otherwiſe they cannot be preſerved in this Country.

Theſe Plants will riſe to the Height of three, four, or five Feet, and will afford a very agreeable Variety amongſt other tender exotic Plants in the Stove.

The Dwarf *Canady* Sort, is pretty hardy, and will endure the Cold of our ordinary Winters in the open Air, provided they are planted in a warm Soil and Situation: If they are planted under Trees, they will thrive much better than when placed in a more open Situation.

DRACUNCULUS PRATENSIS. *Vide* Ptarmica.

DRAGON. *Vide* Dracunculus.

DROSION. *Vide* Ros Solis.

DULCOMARA. *Vide* Solanum.

DUNGS are deſign'd to repair the Decays of exhauſted or worn-out Lands, and to cure the Defects of Land, which are as various in their Qualities as the *Dungs* are that are us'd to meliorate and reſtore them: Some Lands abound too much in Coldneſs, Moiſture, and Heavineſs; others again are too light and dry: And ſo to anſwer this, ſome *Dungs* are hot and light, as that of Sheep, Horſes, Pigeons, *&c.* Others again are fat and cooling, as that of Oxen, Cows, Hogs, *&c.*

And as the Remedies that are to be us'd muſt be contrary to the Diſtempers they are to cure, ſo the *Dung* of Oxen, Cows, and Hogs, muſt be given to clean, dry, light Earths, to make them fatter and cloſer; and hot and dry Dungs to meliorate cold, moiſt, and heavy Lands.

There are two peculiar Properties in *Dungs*, the one is to produce a certain ſenſible Heat, capable of producing of ſome conſiderable Effect; which Properties are ſeldom found but in the *Dungs* of Horſes and Mules, while it is newly made, and a little moiſt: The other Property of *Dung* is, to fatten the Earth, and render it more fruitful.

The *Dung* of Horſes and Mules is of admirable Uſe in Gardens in the Winter-time, becauſe it then animates and enlivens all Things, and ſupplies the Office which is perform'd by the Heat of the Sun in the Summer-time, affording us all the Novelties of the Spring, as *Aſparagus*, *Cucumbers*, *Radiſhes*, *Melons*, *Sallads*, &c. *Horſe-Dung* is the beſt Improvement for *cold*, *jejune* Lands that we can procure in any Quantity: but yet, *Horſe-Dung* being us'd alone, or when 'tis too new, is frequently prejudicial to ſome Lands; and if it be ſpread thin over Lands in the Summer-time, it is of very little Service, becauſe the Sun drawing out all the Virtue and Goodneſs of it, renders it little better than Thatch or dry Straw: And tho' too much of it can ſcarcely be us'd in a Kitchen-Garden for *Cabbages*, *Colliflowers*, and all other Plants that grow there, and require abundance of Nouriſhment, yet it may be a Fault to lay too much of it on Corn-Lands, becauſe it produces abundance of Weeds.

Horſe-Dung being of a very hot Nature, is beſt for cold Lands; and *Cow-Dung* for hot Lands: And being mix'd together, may make a very good Manure for moſt Sort of Soils, and for ſome they may be mix'd with Mud.

Sheep's-Dung and *Deer's-Dung* differ not much in their Quality, and are eſteem'd by ſome the beſt of *Dungs* for cold Clays: Some recommend them to be beat into Powder, and ſpread very thin over Autumn or Spring Crops, about four or five Loads to an Acre, after the ſame Manner as *Aſhes*, *Malt-duſt*, &c. are ſtrew'd.

In *Flanders*, and other Places, they houſe their Sheep at Night in Places ſpread with clean Sand, laid about five or ſix Inches thick; which being laid on freſh every Night, is clear'd out once a Week, and the *Dung* and *Urine* of the Sheep is a very rich Manure, and bears a conſiderable Price, and is an excellent Manure for ſtubborn Lands; and Mr. *Quinteney* is of Opinion, that 'tis the greateſt Promoter of Fruitfulneſs in all Sorts of Ground.

Others recommend *Hog's-Dung* as the fatteſt and moſt beneficial of all Sorts of *Dungs*, and ſay, that one Load of it will go as far as two Loads of other *Dung*, and that it is the beſt of all *Dungs* for Fruit-Trees, eſpecially for *Pear* and *Apple-Trees* in a light Soil, and a very rich *Dung* for *Graſs*. I have often uſed this Dung to Fruit-Trees, when it was well rotted, and have found it the moſt beneficial to them of any Manure.

The *Dung* of *Pigeons*, *Hens*, and *Geeſe*, are great Improvers of Meadow or Corn-Land; the firſt of theſe being the beſt ſuperficial Improvement that can be laid on Meadow or Corn-Land: But before it is us'd, it ought to have lain abroad out of the Dove-houſe ſome time, that the Air may have a little ſweeten'd it, and mollify'd the fiery Heat that is in thoſe *Dungs*.

Eſpecially it is good for cold, wet, clayey Lands; but it ought to be dry'd before it be ſtrew'd, becauſe 'tis naturally apt to clod in Wet, and it ſhould be mix'd with Earth to keep it from clinging together, that it may be ſtrew'd thin, being naturally very hot and ſtrong.

Some recommend the *Dung* of Pigeons, and alſo of other Fowls, as the beſt Manure for *Aſparagus*, *Strawberries*, or any Sorts of Flowers.

Monſieur *Gentil* approves of *Pigeon's-Dung*, as being good for ſuch Trees whoſe Leaves are apt to turn *yellow*, if they grow in free Soils that are rather cold than hot, provided the Heat of it has been abated by lying two or three Years in the Dunghil; but this ſhould be applied in Autumn, and in ſmall Quantities.

This being ſpread about an Inch thick at the Foot of a Tree, whoſe Leaves are *yellow*, and being left there till *March*, he recommends as very uſeful in cold and moiſt Soils.

The *Dung* of Poultry being hot and full of Salts, tends much to facilitate Vegetation, and is abundantly quicker in its Operation than the *Dung* of Animals which feed on Herbs.

Sir *Hugh Plat* ſays, One Load of Grain will inrich Ground more than ten Loads of common *Dung*; which, if it be true, it is rational to ſuppoſe, That if ſimple Grain by only Infuſion in the Mixture of Compoſts, has a very good Effect, it will be more powerful when it has paſs'd thro' the Bodies of Animals.

Human Dung is a great Improver of all cold ſour Lands, and eſpecially if it be mix'd with other *Earths* or *Dungs* to give it a Fermentation.

But there is not any Sort of Manure equal to the cleanſing of *London* Streets for all ſtubborn clayey Soils, the Parts of which will be better ſeparated, and in a much leſs Time with this Manure than any other Compoſt whatever, and where it can be obtain'd, is extremely well worth procuring either for Corn, Graſs, or Garden-Land.

DWARF-TREES. Theſe were formerly in much greater Requeſt than they are at preſent; for, tho' they may have many Advantages to recommend them, yet the Diſadvantages attending them do greatly over-balance; and ſince the introducing of *Eſpaliers* into the *Engliſh* Gardens, *Dwarf-Trees* have been deſtroy'd in moſt good Gardens, for the following Reaſons.

1ſt, The Figure of a *Dwarf-Tree* is very often ſo much ſtudied, that in order to render the Shape beautiful, little Care is taken to procure Fruit, which is the principal Deſign in planting theſe Trees.

2dly, The Branches being ſpread horizontally near the Surface of the Ground, render it very difficult to dig, or clean the Ground, between them.

3dly, Their taking up too much Room in a Garden, (eſpecially when they are grown to a conſiderable Size) for nothing can be ſown or planted between them.

4thly, Theſe Trees ſpreading their Branches near the Ground, do continually ſhade the Surface of the Earth, ſo that neither the Sun nor Air can paſs freely round their Roots and Stems, to diſſipate noxious Vapours, whereby the circumambient Air will be continually replete with crude rancid Vapours, which being drawn in by the Fruit and Leaves, will render its Juices crude and unwholſome as well as ill-taſted.

Theſe Evils being intirely remedied by training the Trees to an *Eſpalier*, hath juſtly gain'd them the Preference; however, if any one has a Mind to have *Dwarf-Trees*, notwithſtanding what has been ſaid, I ſhall lay down a few Rules for their Management.

If you deſign to have *Dwarf Pear-Trees*, you ſhould bud or graft them on *Quince-Stocks*; but as many Sorts of *Pears* will not take, if they are immediately budded, or grafted on *Quince-Stocks*; ſo ſome of thoſe Sorts which will take freely, ſhould be firſt budded on the *Quince-Stocks*; and when theſe have ſhot, the Sorts you intend to cultivate, ſhould be budded into theſe; for Free-Stocks are apt to make them ſhoot ſo vigorouſly, as not to be kept within Bounds: Theſe Grafts or Buds ſhould be put in about four or ſix Inches above the Surface of the Ground, that the Heads of the Trees may not be advanc'd too high; and when the Bud or Graft has ſhot out four Eyes, you ſhould ſtop the Shoot, to force out lateral Branches.

Two Years after Budding, theſe Trees will be fit to tranſplant where they are to remain; for tho' many People chuſe to plant Trees of a greater Age, yet they ſeldom ſucceed ſo well as young ones. The Diſtance theſe Trees ſhould be planted is twenty-five Feet ſquare, for leſs will not do, if the Trees thrive well: The Ground between them may be cultivated for Kitchen-Garden Herbs, while the Trees are young, but you ſhould not ſow or plant too near their Roots.

In order to train your Trees regularly, you ſhould drive Stakes into the Ground round the Tree, to which the Branches ſhould be nail'd down with Liſt in an horizontal Poſition; for if they are ſuffer'd to take a perpendicular Figure while young, they can't be afterwards reduc'd without great Violence to any tolerable Figure. The neceſſary Directions to be afterwards follow'd are, not to ſuffer any Branches to croſs each other; and always in ſhortning any Shoots beſure to leave the uppermoſt Eye outwards, whereby the Hollowneſs in the Middle of the Tree will be better preſerv'd, and be careful to rub off all perpendicular Shoots in the Middle of the Trees, ſo ſoon as they are produc'd. The other neceſſary Rules you'll find under the Article of *Pruning*.

The Sorts of *Pears* which do beſt in *Dwarfs*, are all Summer and Autumn Fruits; for Winter *Pears* are not worth planting in *Dwarfs*, for they ſeldom bear well, nor are ever well-taſted, and commonly are very ſtony.

Apples are alſo planted in *Dwarfs*, moſt of which are now budded or grafted on *Paradiſe* Stocks; but as theſe are for the moſt part of a ſhort Duration, ſo they are not profitable, and are fit only for ſmall Gardens, as a Matter of Curioſity, producing Fruit ſooner and in greater Plenty, than when they are upon *Crab* or *Apple* Stocks.

The Diſtance theſe Trees ſhould be planted, if on *Paradiſe* Stocks, ſhould be ſix or eight Feet; but if on *Crab* Stocks, ſixteen or twenty Feet aſunder each Way. The Management of this being the ſame with *Pears*, I need not repeat it.

Some Perſons alſo plant *Apricocks* and *Plums* for *Dwarfs*, but theſe ſeldom ſucceed well, as being of a tender Conſtitution; and thoſe which will produce Fruit on *Dwarfs*, are much more likely to do ſo when train'd on an *Eſpalier*, where they can be much better manag'd, and therefore I judge it much the better Method, as being more certain, and the Trees will make a better Figure.

E A

EARTH is the principal Matter whereof our Globe conſiſts; the Character of which, according to Dr. *Boerhaave*, is, That it is a *Foſſil Body, neither diſſoluble by Fire, Water, nor Air; that it is inſipid, and tranſparent; more fuſible than Stone; ſtill friable, and containing uſually a Share of Fatneſs.*

There is no ſuch Thing as a ſtrictly ſimple *Earth*; Mr. *Boyle* ſays, That it doth not appear, that Nature any more than Art affords an elementary *Earth*; at leaſt, ſome which appear of the ſimpleſt Sorts are found, upon Examination, to have Qualities not aſcrib'd to pure *Earth*.

Of ſuch *Earths*, ſome are ſimple, and immutable, as *Chalk, Pumice*, and *rotten Stone*; others compound and fatty; of which Kind are all *Boles*, red, white, and brown; *Fullers Earth*; and divers Kinds of Medicinal *Earths*, as the *Cretica, Hungarica, Lemnian Earth*, and others.

Which *Earths* are all reſolvable into Oil, a little acid Salt, *&c.* and a *Calx*, which is the *Baſis*, or the *Earth* properly ſo call'd.

Sand is by Naturaliſts generally rank'd as a Species of *Earth*, tho' not very properly; in that *Sands*, ſtrictly ſpeaking, are a Sort of Cryſtals, or little tranſparent Pebbles, and are calcinable, and by the Addition of a fix'd Alcaline Salt, fuſible, and convertible into Glaſs.

The fat *Earth* is render'd fertile by the Means of *Sand*, and becomes fit to feed and nouriſh Vegetables, *&c.* for pure *Earth* is liable to coaleſce into a hard coherent Maſs, as in Clay; and Earth thus imbodied, and as it were glu'd together, would be very unfit for the Nouriſhment of Plants.

But if hard *Sand*, i. e. *Cryſtals*, which are indiſſoluble in Water, and ſtill retain the ſame Figure, be intermix'd with ſuch *Earth*, they will keep the Pores of the *Earth* open, and the *Earth* itſelf looſe and incompact, and by that means give Room for the Juices to move, aſcend, *&c.* and for Plants to be nouriſh'd thereby.

Thus a Vegetable being planted either in the *Sand* alone, or in the fat *Glebe* and *Earth* alone, receives no Growth or Increment, but is either ſtarv'd or ſuffocated; but mix the two, and the Maſs becomes fertile.

In effect, by means of *Sand* the *Earth* is render'd, in ſome meaſure, Organical, Pores and Interſtices being hereby maintain'd or preſerv'd, ſomething analagous to Veſſels is effected; by which the Juices of the *Earth* may be convey'd, prepar'd, digeſted, circulated, and at length excern'd and thrown off in the Roots of Plants.

The *Earth* is made up of two Parts: The firſt the *containing* Part, *i. e.* the *Body, Bed*, or *Couch*; the ſecond Part *contained*, and thoſe are the *nitrous* or *ſulphureous Particles* or *prolifick Salts*. The firſt is a lifeleſs inanimate Maſs, and is only the Receptacle of the other: For the Earth conſider'd ſimply, and abſtracted from the before-mention'd *nitrous* and *prolifick Salts*, is a lifeleſs, dead, and inanimate Maſs; but by the Co-operation of Water, Sun, and Air, is put into Motion, and promotes the Work of Vegetation: But if it were ſtript of thoſe prolifick Salts and ſpirituous Particles, would produce no Manner of Plant, Herb, *&c.* that ſhould be planted or ſown in it.

Theſe *nitrous Particles* or *prolifick Salts*, are of various and different Qualities; and according as the *Earth* is more or leſs ſtor'd with all or ſome of them, it is more or leſs productive; and according as it abounds with ſome of them more than others, differing from one another in Contexture, it conſtitutes the different Species or Kinds of Soils adapted to the Propagation of different Plants, the Pores of whoſe Roots are form'd to receive, and whoſe Nature is to attract thoſe Salts that are congenial to them.

Some diſtinguiſh *Earths* into three Claſſes, *Sand, Loam*, and *Clay*; as thoſe upon one or other of which all others do in ſome reſpects depend.

Gravel, and all the open Soils, till the *Loam* is come at, are of the ſandy Kind.

Thoſe binding *Earths* from the *Loam* downwards, till the Stiffneſs of Chalk may be come at, may be reckon'd of the *Clay* Kind.

All theſe Sorts of *Earths* have a little Tendency to Vegetation, and have their Salts proper for it, but in a different Proportion; as a Peck of *Clay* may probably have double the Quantity of *Salts* in it that a Peck of *Loam* has; and a Peck of *Loam* may have twice the Quantity of *Salts* that Peck of *Sand* has.

Loam. Some call the ſuperficial *Earth* that we meet with in *England* by this Name, without having regard to what Proportions of *Sand* and *Clay* it contains: Others again call that *Earth Loam* that inclines more to *Clay* than *Sand:* Some by *Loam* mean that Sort of *Earth* that equally partakes of *Sand* and *Clay*, being a Medium between *Sand* and *Clay*, which they call *Mother-Earth*.

This *Mother-Earth*, they ſay, may be in Colour either black or yellow; and of which of theſe Colours ſoever it be, Plants of all Sorts will grow in it.

Sand and *Clay* likewiſe produce certain Plants which are natural to each of them, and conſequently will thrive better in them than in any other Soil.

But *Sand* is apt to precipitate thoſe Plants that are ſet in it, earlier than *Clay*, and will cauſe them to germinate near a Month ſooner than thoſe that grow in *Clay*, and that for this Reaſon, that the *Salts* which are in the *Sand* are liable to be put in Motion by the leaſt Approach of the Warmth of the Sun; but as *Sand* is quick in the Operation, ſo the *Salts* are ſoon exhal'd and ſpent.

Clay: The Parts of *Clay* are more cloſely compacted together, and do not ſo eaſily give out thoſe *Salts* that are contain'd in it; nor can the Fibres of every tender Plant make their Way thro' it in queſt of their proper Nutriment.

But if the Parts of the *Clay* be open'd, by digging and breaking it into ſmall Particles, and thoſe Parts be kept open by a Mixture of ſome ſharp Sand, or ſome other Body of the like Quality, the Effects of its Vigour will plainly appear.

Some diſtinguiſh the ſeveral Temperaments of the *Earth* either into a *light, ſandy*, or *looſe* Contexture, or into thoſe of a *ſtiff, clayey*, or *cloſe* one; either of which have their reſpective good Qualities, and all of them, when they are in their Extremes, require Art to render them uſeful and beneficial in the Production and Growth of Plants.

A *light, ſandy*, or *looſe Earth* requires a proper Ligature, and ſhould have a Compoſt of a heavier Nature; and thoſe that are *heavy, clayey*, and *cloddy*, ſhould have a Compoſt of a more fiery, ſprightly Nature, that will inſinuate itſelf into the *heavy, lumpy,*

lumpy, indigeſted Clods, which would otherwiſe very much obſtruct the Buſineſs of Vegetation.

Some Authors who treat of the Qualities of *Earth*, ſay, a good *Earth* ſhould be of a *blackiſh* Colour, *gravelly*, *fat*, *pliant*, or *eaſy* to be digg'd, and that it ſhould be neither *cold* nor *light*; that it ought to have no ill Smell nor Taſte; and that it ought to be of the ſame Quality three or four Feet deep for Trees, which, if they have not that Depth, will languiſh and decay, after they have been planted ſix Years. But this is not true in Fact; for moſt Trees will thrive very well, if they have two Feet Depth of good *Earth*, eſpecially Fruit-Trees, which produce the moſt generous Fruits when their Roots ſpread near the Surface of the Earth.

In order to know whether the *Earth* has any ill Smell or Taſte, they direct to lay a Handful of it to ſoak in Water for ſeven or eight Hours, and afterwards to ſtrain it, and taſte and ſmell it; by which, the Taſte or Smell will eaſily be perceiv'd.

EARWIGS.

Theſe are very troubleſome Vermin in a Garden, eſpecially where *Carnations* are preſerved; for they are ſo fond of theſe Flowers, that if Care is not taken to prevent them, they will intirely deſtroy them, by eating off the ſweet Part at the Bottom of the Leaves. To prevent which, moſt People have Stands erected, which have a Baſon of Earth or Lead round each Supporter, which is conſtantly kept fill'd with Water. See the Article *Carnation*.

Others hang the hollow Claws of Crabs and Lobſters upon Sticks in divers Parts of the Garden into which theſe Vermin get; and by often ſearching them, you will deſtroy them without much Trouble; which will be of great Service to your Wall-Fruit, for theſe are great Deſtroyers thereof.

EBULUS. *Vide* Sambucus Humilis.

ECHINATE SEEDS; [of *Echinus*, Lat. a *Hedge-hog*] ſuch Seeds of Plants as are prickly and rough.

ECHYNOMELOCACTUS. *Vide* Melocactus.

ECHINOPHORA; of 'Εχίνος, a *Hedge-hog*, and φὲρω, Gr. *to bear*] Prickly-headed Parſnip.

The *Characters* are;

The Cup of the Flower conſiſts of one Leaf, which is divided into five Parts, and expands in Form of a Star, in which is included the Foot-ſtalk of the Umbel; the Fruit conſiſts of one prickly Veſſel, in which is contain'd one long Seed.

We have but one *Specie* of this Plant, which is,

ECHINOPHORA, *paſtinacæ folio. C. B.* Echinophora, with a Parſnip-Leaf.

There is no great Uſe or Beauty in this Plant; but it is preſerv'd in curious Botanick Gardens, for Variety-ſake. It may be propagated by ſowing the Seeds ſoon after they are ripe, or very early in the Spring; and when the Plants are come up, they ſhould be ſingled out, ſo as to remain about eight or ten Inches aſunder. The ſecond Year after ſowing they will produce ripe Seeds.

ECHINOPUS; [of 'Εχίνος, a *Hedge-hog*, becauſe the Heads of this Plant reſemble this Animal] Globe-Thiſtle, *vulgo*.

The *Characters* are;

It hath the whole Appearance of a Thiſtle; *the Leaves are produc'd alternately; the Florets conſiſt of one Leaf, which is divided into five Segments, and is hollow; and each ſingle Floret has a ſcaly Cup; the Florets are collected into a ſpherical Head, which has one common Cup or Covering.*

The *Species* are;

1. ECHINOPUS *major. J. B.* Greater Globe-Thiſtle.
2. ECHINOPUS *major humilior, floribus albidis. Flor. Bat.* Greater Dwarf Globe-Thiſtle, with whitiſh Flowers.
3. ECHINOPUS *minor annuus, capite magno. Tourn.* Leſſer annual Globe-Thiſtle, with a large Head.

The firſt of theſe Plants hath been an old Inhabitant of the *Engliſh* Gardens, where it hath had a Place more for Variety, than any particular Beauty.

The ſecond Sort is a Variety which hath been obtain'd from Seeds of the former. Theſe Plants may be propagated by ſowing their Seeds in the Spring of the Year in a light Soil: And when the Plants are ſtrong enough to remove, they may be tranſplanted into the Middle of large Borders, or in any abject Part of the Garden; for they are too large to ſtand amongſt nicer Plants, which would be greatly injured by their large Leaves. The ſecond Year after ſowing they will produce Flowers; and if the Autumn is not too cold or wet, will perfect Seeds: But the Roots of theſe will abide three or four Years, and produce Flowers and Seeds annually.

The third Sort is an annual Plant, and requires to be ſown early, as alſo to have an open warm Situation; otherwiſe it will not produce good Seeds in this Country. This Plant is of ſmall Growth, and ſo may the better be preſerv'd in a warm Border amongſt other curious Plants.

ECHINUS; *Lat.* is the prickly Head, or Cover of the Seed, or Top of any Plant; ſo call'd, from its Likeneſs to a *Hedge-hog*.

ECHIUM; [of 'Εχίς, Gr. a *Viper*, becauſe the ripe Seed of this Plant reſembles the Head of a Viper. It is call'd *Herba Viperaria*, becauſe the Antients believ'd that this Plant kill'd Vipers] Vipers Bugloſs.

The *Characters* are;

The Cup of the Flower is large, and divided into five long ſlender Segments; the Flower conſiſts of one Leaf, is ſhap'd like a Funnel, and ſomewhat inflected, having its upper Part ſtretch'd out to a greater Length than the lower; the upper Part or Galea of the Flower is divided into two, and the lower Part or Beard into three Parts; in the Middle of the Flower are produc'd five Stamina (or Threads) which are reflex'd; each Flower is ſucceeded by four Seeds, which are in form of a Viper's Head.

The *Species* are;

1. ECHIUM *vulgare. C. B.* Common Vipers Bugloſs.
2. ECHIUM *majus & aſperius, flore albo. C. B.* Great rough Vipers Bugloſs, with a white Flower.
3. ECHIUM *majus & aſperius, flore dilute purpureo. Bot. Monſ.* Great rough Vipers Bugloſs, with a Flower of a pale purple Colour.
4. ECHIUM *ampliſſimo folio, Luſitanicum. Tourn. Portugal* Vipers Bugloſs, with a large Leaf.
5. ECHIUM *Creticum latifolium rubrum. C. B.* Broad-leav'd *Candia* Vipers Bugloſs, with a red Flower.
6. ECHIUM *Creticum anguſtifolium rubrum. C. B.* Narrow-leav'd *Candia* Vipers Bugloſs, with a red Flower.
7. ECHIUM, *foliis anguſtis & villoſis. Tourn.* Vipers Bugloſs, with narrow hairy Leaves.

There are ſeveral other Varieties of this Plant, which are preſerv'd in curious Botanick Gardens; but theſe here mention'd are the chief Sorts which I have obſerv'd in *England*. The firſt Sort is found wild upon dry chalky Hills and gravelly Soils in divers Parts of *England*, and is ſometimes uſed in Medicine: But there are none of the Varieties which are cultivated for their Beauty; tho' I think the firſt, fifth, and ſixth Sorts do deſerve a Place in ſome dry abject Part of the Garden, where little elſe will grow, for the ſake of Variety, and the long Continuance of their Flowers. They are moſt of them biennial Plants; the Seeds being ſown in the Spring, will the ſecond Summer after produce Flowers and Seeds, after which they ſeldom continue: They all delight in a rubbiſhy gravelly Soil, and will grow upon the Tops of old Walls or Buildings, where when once they have eſtabliſh'd themſelves, they will drop their Seeds, and thereby maintain a Succeſſion of Plants without any Care; and on theſe Places they appear very beautiful.

EDERA QUINQUEFOLIA. *Vide* Vitis.

EDGINGS. The beſt and moſt durable Plant for *Edgings* in a Garden, is *Box*, which, if well planted, and rightly manag'd, will continue in Beauty for ſeveral Years: The beſt Seaſon for planting this, is either in the Autumn, or very early in the Spring; for if you plant it late, and the Seaſon ſhould prove hot and dry, it will be very ſubject to miſcarry, unleſs great Care is taken to ſupply it with Water. The beſt Sort for this Purpoſe is the *Dwarf Dutch-Box*.

Theſe *Edgings* are only planted upon the Sides of Borders next Walks, and not (as the Faſhion was ſome Years ago) to plant the *Edgings* of Flower-beds, or the *Edges* of Fruit-borders in the Middle of Gardens, unleſs they have a Gravel Walk between them, which renders it proper to preſerve the Walks clean, by keeping the Earth of the Borders from waſhing down in hard Rains.

It was alſo the Practice formerly, to plant *Edgings* of divers Sorts of Aromatick Herbs, as *Thyme*, *Savory*, *Hyſſop*, *Lavender*,

der, &c. But theſe being ſubject to grow woody, ſo that they can't be kept in due Compaſs, and in hard Winters being often kill'd in Patches, whereby the *Edgings* are render'd incomplete, they are now ſeldom us'd for this Purpoſe.

Some People alſo make *Edgings* of *Daiſies*, *Thrift*, *Catchfly*, and other flowering Plants; but theſe alſo will require to be tranſplanted every Year, in order to have them handſome; for they ſoon grow out of Form, and are ſubject alſo to decay in Patches, ſo that there is not any Plant which ſo compleatly anſwers the Deſign as *Dwarf-Box*, which muſt be preferr'd to all others.

EFFLORESCENCE, *Lat.* The *Blowing out of a Flower.*

To EGERMINATE, *Lat.* To *bud* or *ſpring out.*

ELATERIUM; [ἐλατήριον, of ἐλαύνω, Gr. *to agitate*, as tho' a bent Bow which returns to its former State: Or it is ſo call'd of its Fruit, which if it be touch'd lightly, ſcatters itſelf; but the ripe Fruit is carefully to be gather'd between Cloths, or in a Pitcher, that it may diſcharge itſelf in that, that it may not affect the Eyes] The Wild Cucumber.

The *Characters* are;

The Branches are ſomewhat like thoſe of the Cucumber, *but have no Tendrils; the Fruit is prickly, and when ripe, burſts with great Elaſticity, and abounds with fœtid Juice.*

We have but one *Specie* of this Plant, which is;

ELATERIUM *officinarum. Boerh. Ind.* This is the *Cucumis ſylveſtris, Aſininus dictus*, of *Caſpar Bauhin.* Wild Cucumber.

This Plant is cultivated in ſome Gardens for Medicinal Uſe, but is chiefly preſerv'd in curious Gardens for its Variety, as alſo for Diverſion; for when the Fruit is ripe, if you offer to gather it, it burſts and caſts its Juice and Seeds with great Elaſticity, for which it is call'd by ſome *Noli me Tangere*, or *Touch me not:* Which Appellation may be given to many other Plants on this Account.

It may be propagated by ſowing the Seeds in the Spring of the Year in an open warm Border; and when the Plants are come up, they may be tranſplanted into open Beds or Borders, about 6 or 8 Feet Diſtance from each other; for the Vines will ſpread very far, eſpecially if the Ground is good in which they are planted: Theſe produce their Fruit in Autumn, which if you ſuffer to fall off, and emit their Seeds, will afford a plentiful Supply of Plants without any farther Care.

ELATINE. *Vide* Linaria.

ELÆAGNUS; [from ἔλαια, an Olive, and ἁγνὸς, *vitex*; becauſe this Plant hath Leaves like thoſe of the Chaſte-Tree, and a Fruit like an Olive] Oleaſter, or Wild Olive.

The *Characters* are;

It hath a tubulous Flower, conſiſting of one Leaf, and cut into four Segments, whoſe Calyx afterward becomes a Fruit ſhaped like an Olive, incloſing a Stone of the ſame Form.

The *Species* are;

1. ELÆAGNUS *orientalis latifolius, fructu maximo. Tourn. Cor.* Eaſtern broad-leav'd Wild Olive, with a large Fruit.
2. ELÆAGNUS *orientalis anguſtifolius, fructu parvo, olivæformi ſubdulci. Tourn. Cor.* Eaſtern Wild Olive, with narrow Leaves, and a ſmall ſweet Olive-ſhap'd Fruit.
3. ELÆAGNUS *orientalis anguſtifolius, fructu minimo rotundiori & ſubacido. Tourn. Cor.* Eaſtern narrow-leav'd Wild Olive, with a ſmall roundiſh and acid Fruit.
4. ELÆAGNUS *non ſpinoſa, foliis anguſtis & longiſſimis, fructu parvo olivæformi.* Wild Olive without Spines, narrow long Leaves, and a ſmall Olive-ſhap'd Fruit.

The firſt and third Sorts Dr. *Tournefort* obſerved growing in ſeveral Iſlands of the *Archipelago*; the ſecond Sort is found in great Plenty upon the Hills in *Spain*, *Italy*, and ſome Parts of *Germany*; the fourth Sort is the moſt common in the *Engliſh* Gardens, and hath been by moſt botanic Authors mentioned for the ſecond Sort; tho' by comparing of them together, they appear very different; for the Leaves of the ſecond are much ſhorter than thoſe of the fourth; and the Branches are beſet with ſharp Thorns between the Leaves; whereas the fourth Sort hath no Spines on it: But where this is a Native, I cannot determine, tho' probably it was found with the ſecond Sort in ſome of the Southern Parts of *Europe.*

Theſe Plants may be propagated by laying down the young Shoots in Autumn, which will take Root in one Year, when they may be cut off from the old Trees, and either tranſplanted into a Nurſery for two or three Years, to be trained up, or into the Places where they are to remain. The beſt Seaſon for tranſplanting of theſe Trees, is in the latter End of *February*, or the Beginning of *March*, tho' they may be removed at *Michaelmas*, provided the Roots are mulched to protect them from ſevere Froſt in Winter. Theſe Plants ſhould be placed where they may be protected from ſtrong Winds; for they grow very freely, and are very ſubject to be ſplit down by the Wind, if they are too much expoſed.

Theſe Trees commonly grow to eighteen or twenty Feet high; and when they are intermixed with other Trees of the ſame Growth, make a pretty Diverſity; for the Leaves of theſe Trees are of a ſilver Colour, ſo are eaſily diſtinguiſhed at a Diſtance. In *June* theſe Trees produce great Quantities of ſmall yellowiſh Flowers of a very ſtrong Scent, and ſometimes they produce Fruit in *England.*

ELEPHANTOPUS; [of ἔλεφας, an Elephant, and πȣ̃ς, a Foot] Elephant's-Foot; ſo called by Monſieur *Vaillant*; becauſe, he ſays, the under Leaves of the firſt Sort ſomewhat reſemble an Elephant's Foot.

The *Characters* are;

It hath a diſcous Flower, compoſed of ſeveral Florets which are hermaphrodite, contained in one Flower-cup, which is cut into ſeveral Segments almoſt to the Bottom; the Bottom of the Calyx is flat, and filled with Ovaries, which are beſet on the Top with Hairs; the Diſks are jointed upon a common Placenta, and form a ſort of Sheaf garniſhed with a Foliage.

The *Species* are;

1. ELEPHANTOPUS *conyzæ folio. Vaill. Mem. Acad. Scien.* 1719. Elephant's-Foot, with a fleabane Leaf.
2. ELEPHANTOPUS *folio ſinuato. Vaill. Mem. Acad. Scien.* 1719. Elephant's-Foot with a ſinuated Leaf.
3. ELEPHANTOPUS *helenii folio, flore purpuraſcente.* Elephant's-Foot, with an elecampane Leaf, and purpliſh Flowers.

The firſt Sort grows in great Plenty in *South Carolina*, where it is a very common Weed; for from the Earth in which ſome Plants were brought over from thence, I have frequently had this Plant come up as a Weed. The ſecond and third Sorts are very common in *Jamaica*, and in ſeveral Parts of the *Spaniſh Weſt-Indies*; from whence I have received Seeds and Specimens, which were collected by my late ingenious Friend Dr. *William Houſtoun.*

Theſe Plants are propagated by Seeds, which ſhould be ſown on a Hot-bed in the Spring; and when the Plants are come up, they muſt be tranſplanted into Pots filled with light freſh Earth, and plunged into a Hot-bed of Tanners-bark, obſerving to water and ſhade them until they have taken Root; then you ſhould let them have a large Share of freſh Air in warm Weather, and give them plenty of Water: With this Management the firſt and ſecond Sorts will flower in *Auguſt*, and if the Autumn proves favourable, will ripen their Seeds in *October*; but the Plants ſhould be placed in a Stove after the Seeds are perfected, if you deſign to preſerve them through the Winter.

The third Sort is hardier than either of the former, and may be preſerved thro' the Winter in a Green-houſe, without any additional Heat; this Plant dies to the Root every Autumn, and riſes again the following Spring; but it ſeldom flowers, unleſs the Seaſon be very warm, or that the Plants are forwarded by a Hot-bed in the Spring. This Plant hath been long known in the *European* Gardens, under the Title of *Scabioſa Indica Bontii.*

ELEPHAS. *This Plant was ſo named, from the Reſemblance which the Flower has to an Elephant's Head.*

The *Characters* are;

It hath an anomalous perſonated Flower, conſiſting of one Leaf, which hath two diſtinct Lips; the upper one reſembles an Elephant's Trunk, but the under one is divided into ſeveral Parts; from whoſe Cup ariſes the Pointal, fixed like a Nail in the hinder Part of the Flower, which afterward becomes a Fruit divided into two Cells, which contain many oblong Seeds.

The *Species* are;

1. ELEPHAS *Italica, flore magno, proboſcide ſurrecta. Tourn.* *Italian* Elephas, with a large Flower, whoſe upper Lip or Trunk is erect.
2. ELEPHAS *orientalis, flore parvo, proboſcide ſurrecta. Tourn.* Eaſtern Elephas, with a ſmall Flower, whoſe upper Lip or Trunk is erect.

3. ELEPHAS *orientalis, flore magno, proboſcide incurva. Tourn.* Eaſtern Elephas, with a large Flower, whoſe upper Lip or Trunk is bent downward.

The firſt Sort grows naturally in ſome Parts of *Italy*, from whence the Seeds have been procured by ſome curious Perſons; but this Plant is very rare in *England* at preſent. The other two Sorts were diſcovered by Dr. *Tournefort*, in the *Levant*, who ſent the Seeds to the *Royal Garden* at *Paris*; where the Plants were raiſed, and have ſince been diſtributed to ſeveral curious Perſons in *Europe*.

Theſe Plants may be propagated by Seeds, which ſhould be ſown on a Bed of light freſh Earth the Beginning of *March*; when the Plants begin to appear, they ſhould be kept clear from Weeds; and in dry Weather they muſt be frequently watered, which will greatly promote their Growth. When the Plants are about two Inches high, they ſhould be carefully taken out of the Bed, and tranſplanted, ſome of them into ſmall Pots, filled with light freſh Earth, and the others into a Bed of freſh Earth in a warm Situation. Theſe Plants muſt be ſcreened from the Sun until they have taken Root; after which time they may be expoſed to the open Air, obſerving to water them in dry Weather, as alſo to keep them clear from Weeds: when thoſe Plants, which were planted in Pots, have grown ſo much as to fill the Pots with their Roots, they muſt be ſhaken out of them, and their Roots pared, and then put into Pots a little larger than the former; which muſt be filled with freſh Earth, and then placed into an open Situation, obſerving to water them duly in dry Weather. In this Place they may remain until the Beginning of *November*, when they ſhould be removed and placed under a Hot-bed Frame, where they may be ſheltered from ſevere Froſt in Winter; but in mild Weather they ſhould have as much free Air as poſſible; ſo that the Glaſſes of the Hot-bed muſt be taken off every Day when the Weather is good. In the Spring ſome of theſe Plants may be ſhaken out of the Pots, and planted in a warm Border, where they will thrive, and produce their Flowers, and ſometimes will perfect their Seeds in this Country.

Thoſe Plants which are planted in a Bed of good Earth, will require no other Culture but to keep them clear from Weeds, and in dry Weather they muſt be duly watered; but if the Winter ſhould prove very ſevere, it will be proper to cover them with Mats or Peaſe-haulm, to protect them from the Froſt; and in the Spring, the Plants may be taken up, and tranſplanted into the Borders of the Pleaſure-garden, where they are deſigned to remain. As theſe Plants are in danger of being deſtroyed in very cold Winters, ſo it will be proper to keep two or three Plants of each Kind in Pots, which may be ſheltered from ſevere Froſt, in order to preſerve the *Species*.

ELICHRYSUM, or HELIOCHRYSON: [ἐλιόχρυσον is compos'd of ἥλιος, *Sol*, the *Sun*; and of χρυσὸς, *Aurum*, *Gold*, becauſe the Cup of the Flower is for the moſt part of a Gold-colour] Eternal Flower.

The *Characters* are;

The Disk of the Flower contains many hermaphrodite Florets; in the Centre of each of theſe ariſes the Ovary, which is crown'd with Hairs, and is ſupported by a naked Placenta; theſe are all contain'd in a ſcaly Cup, which conſiſts of dry Membranes, and is, for the moſt part, of a ſplendid Colour.

The *Species* are;

1. ELICHRYSUM, *ſeu ſtœchas citrina anguſtifolia. C. B.* Goldylocks or Caſſidony.

2. ELICHRYSUM *montanum, flore rotundiori candido. Tourn.* Cats-foot or Mountain Caſſidony, with a white round Flower.

3. ELICHRYSUM *montanum, flore rotundiori variegato. Tourn.* Cats-foot or Mountain Caſſidony, with a round variegated Flower.

4. ELICHRYSUM *Americanum latifolium. Tourn.* Broad-leav'd *American* Eternal-Flower.

5. ELICHRYSUM *ſylveſtre latifolium, flore parvo ſingulari. Tourn.* Broad-leav'd wild Eternal-Flower, with a ſmall ſingle Flower.

6. ELICHRYSUM *ſylveſtre latifolium, flore magno ſingulari. Tourn.* Broad-leav'd wild Eternal-Flower, with a ſingle large Flower.

7. ELICHRYSUM *ſylveſtre latifolium, capitulis conglobatis. C. B.* Broad-leav'd wild Eternal-Flower, with many Heads cloſely united.

8. ELICHRYSUM, *flore ſuave rubente. Hort. Cath.* Eternal-Flower, with a ſoft Red-colour'd Flower.

9. ELICHRYSUM *Africanum fœtidiſſimum, ampliſſimo folio, calyce argenteo. Tourn.* Stinking *African* Eternal-Flower, with a broad Leaf and a ſilver-colour'd Cup.

10. ELICHRYSUM *Africanum, fœtidiſſimum, ampliſſimo folio, calyce aureo. Tourn.* Stinking *African* Eternal-Flower, with a broad Leaf and a gold-colour'd Cup.

11. ELICHRYSUM *Orientale. C. B. Eaſtern* Eternal-Flower.

12. ELICHRYSUM *arboreum Africanum, ſalviæ folio odorato. Boerh. Ind. African*-Tree Eternal-Flower, with a ſweet-ſmelling Sage-Leaf.

13. ELICHRYSUM *Africanum, folio oblongo, ſubtus incano, ſupra viridi, flore luteo. Boerh. Ind. African* Eternal-Flower, with a longiſh Leaf, hoary underneath, but green on the upper Part, and a yellow Flower.

14. ELICHRYSUM *Africanum fruteſcens, foliis crithmi marini. Hort. Amſt.* Shrubby *African* Eternal-Flower, with Leaves like the Samphire.

15. ELICHRYSUM *Africanum fruteſcens, foliis ſtœchados citrinæ, flore aureo. Boerh. Ind.* Shrubby *African* Eternal-Flower, with Leaves like the Golden Caſſidony.

16. ELICHRYSUM *Africanum lanuginoſum latifolium, calyce floris argenteo & ampliſſimo. Olden.* Woolly *African* Broad-leav'd Eternal-Flower, with an ample ſilver-colour'd Cup.

17. ELYCHRYSUM *Africanum tomentoſum fruteſcens, calyce argenteo. Com. Pl. Rar. African* ſhrubby Eternal-Flower, with woolly Leaves and a ſilver-colour'd Flower-Cup.

18. ELICHRYSUM *Africanum fruteſcens, anguſtis & longioribus foliis incanis. Hort. Amſt.* Shrubby *African* Eternal-Flower, with long narrow hoary Leaves.

19. ELICHRYSUM *anguſtiſſimo folio. Tourn.* The moſt narrow-leav'd Golden Caſſidony.

20. ELICHRYSUM *umbellatum maritimum Hiſpanicum. Tourn. Spaniſh* maritime umbellated Golden Caſſidony..

21. ELICHRYSUM *ſeu Stœchas citrina latifolia. C. B. P.* Broad-leav'd Golden Caſſidony.

22. ELICHRYSUM *Germanicum, calyce ex aureo rutilante. Tourn. German* Goldylocks, with a reddiſh golden Empalement.

23. ELICHRYSUM *Germanicum, calyce ſanguineo. Tourn. German* Goldylocks, with a Blood-coloured Empalement.

24. ELICHRYSUM *anguſtifolium incanum, maximo flore. Tourn.* Hoary narrow-leav'd Golden Caſſidony, with a large Flower.

25. ELICHRYSUM *lavendulæ folio breviori, floribus conglobatis minime luteis. D. Sherard. Raii ſup.* Golden Caſſidony, with a ſhorter lavender Leaf, and conglobated Flowers, which are very little yellow.

26. ELICHRYSUM *latifolium Hiſpanicum, corymborum ſquamulis & floribus amplis ſulphureis. Pluk. Almag.* Broad-leav'd *Spaniſh* Golden Caſſidony, with large yellow Flowers.

27. ELICHRYSUM *latifolium villoſum, alato caule, odoratiſſimum. Pluk. Phyt.* The moſt ſweet-ſmelling hairy broad-leav'd Golden Caſſidony, with a winged Stalk.

28. ELICHRYSUM *orientale, foliis amplioribus ſubrotundis. Tourn.* Eaſtern Golden Caſſidony, with larger roundiſh Leaves.

29. ELICHRYSUM *orientali ſimile, calyce florum argenteo. Tourn.* Golden Caſſidony reſembling the Eaſtern one, with a ſilver Empalement.

30. ELICHRYSUM *orientale vernum anguſtifolium. Tourn.* Narrow-leav'd Eaſtern Spring Golden Caſſidony.

31. ELICHRYSUM *orientale, leucoii folio viridi. Tourn.* Eaſtern Golden Caſſidony, with a green July-flower Leaf.

32. ELICHRYSUM *orientale glutinoſum, lavendulæ folio. Tourn.* Glutinous Eaſtern Golden Caſſidony, with a Lavender Leaf.

33. ELICHRYSUM *Africanum, folio oblongo anguſto, flore rubello poſtea aureo. Boerh. African* Golden Caſſidony, with a narrow oblong Leaf, and a red Flower turning to a Yellow.

34. ELICHRYSUM *Africanum lanuginoſum latifolium, calyce floris argenteo & ampliſſimo. Oldenl.* Broad-leav'd woolly *African* Golden Caſſidony, with a very large ſilver Empalement.

35. ELICHRYSUM *Africanum lanuginoſum, anguſtiſſimo folio, calyce floris argenteo & ampliſſimo. Oldenl.* Woolly *African* Golden Caſſidony, with a very narrow Leaf, and a large ſilver Empalement.

36. ELICHRYSUM *Africanum fruteſcens, coridis folio. Oldenl.* Shrubby *African* Goldylocks, with a Coris Leaf.

37. ELICHRYSUM *Africanum incanum tomentoſum, foliis ſubrotundis. Oldenl.* Woolly hoary *African* Goldylocks, with roundiſh Leaves.

38. Eʟɪᴄʜʀʏsᴜᴍ *Africanum umbellatum odoratum luteum. Oldenl.* Yellow ſweet-ſmelling umbellated *African* Goldy-locks.

The firſt of theſe Sorts hath no great Beauty, but it being a medicinal Plant, is preſerv'd in Phyſick Gardens. This ſeldom produces good Seeds in *England*, but is very eaſily propagated by planting Slips or Cuttings in a ſhady Border, any time from *April* to *Auguſt*; which, if carefully ſupply'd with Water, will puſh out Roots in a Month's time, and may then be remov'd to the Place where it is to remain for good.

This delights in a dry warm Soil, that is not too rich; for if the Soil be wet, or over-dung'd, it will cauſe this Plant to make ſtronger Shoots in Summer, but then it will be liable to be deſtroy'd with a little cold Weather in Winter. This Plant may be train'd up to a regular Head, if proper Care be taken of it while young, and will grow to the Height of three or four Feet.

The ſecond and third Sorts are Inhabitants of the Northern Mountains in *Yorkſhire*, *Cumberland*, &c. Theſe Plants grow very cloſe to the Ground, and increaſe very faſt from the Off-ſets, which are produc'd in great Plenty on every Side the Plants, which emit Roots from their Joints as they trail upon the Ground, ſo that in a ſhort time they will overſpread the Ground where they are planted.

Theſe Plants produce ſmall Bunches of ſoft dry Flowers, which if gather'd when they are in Beauty, and preſerv'd in a dry Place, will continue freſh and fair for ſome Years, for which Reaſon they deſerve a Place in every good Garden, to increaſe the Varieties of theſe Flowers, which will afford Pleaſure at a Seaſon when the Ground is ſo lock'd up, that none of the flowery Tribe abroad appears above-ground. Theſe Plants will grow in a ſhady dry Place in any remote Part of a Garden, and are by ſome planted for Edgings to North Borders.

The fourth Sort is a great Rambler in a Garden, and ſhould therefore be either confin'd to Pots, or planted in ſome abject Part of the Garden, in a Place by itſelf; for if it ſtand near any other Plants or Flowers, it will be apt to over-run and deſtroy them; for the Roots creep far under-ground, and will ariſe at a great Diſtance from the old Plant: But however as the Flowers are very beautiful amongſt others of the perpetual Kind, they ſhould not be wanting in a good Garden. This, though ſtil'd an *American* Plant, yet is thought to be a Native of ſome of the warm European Countries. It delights in a dry warm Soil, and increaſes plentifully by the Off-ſets.

The fifth and ſixth Sorts are Plants of no great Beauty: They are preſerv'd in Botanick Gardens for Variety ſake, but are ſeldom cultivated in Gardens for Pleaſure. They may be propagated, either by ſowing their Seeds in the Spring on a moderate Hot-bed, or by planting Cuttings or Slips in any of the Summer Months: But theſe Plants producing Seeds in Plenty, it is the common Method to increaſe or maintain them by Seeds. Theſe muſt be planted in Pots fill'd with light ſandy Earth, and muſt be ſhelter'd in Winter, giving them as much free open Air as poſſible in mild Weather, and often refreſhing them with Water: With this Management they may be train'd up to the Height of three or four Feet, and will grow ſhrubby; but if ſuffer'd to remain abroad, they will not ſurvive the Winter.

The ſeventh Sort is an Annual, and is a Plant of very little Beauty, and is only preſerv'd for Variety, and will require no farther Care than to ſuffer the Seeds to fall upon the Ground, which will ariſe, and afford an abundant Supply of Plants.

The eighth Sort is an abiding Plant, which deſerves a Place in the moſt curious Gardens for the Beauty of its Flowers. This is propagated by planting Cuttings in any of the Summer Months, which ſhould be put into Pots fill'd with light ſandy Soil, and plung'd into a moderate Hot-bed, to facilitate their Rooting; after which they may be expos'd to the open Air, and ſome of them may be planted into a warm dry Border, where they will endure the Cold of our ordinary Winters without any Shelter; but 'tis adviſeable always to preſerve ſome in Pots under Cover in Winter, leſt thoſe abroad ſhould be deſtroy'd, as it ſometimes happens in very ſevere Froſts.

This Plant producing Flowers which are of a fine ſoft red Colour, are a very great Ornament in Winter, when intermix'd with the ſeveral Varieties of Eternal Flowers, in Glaſſes or Baſons fill'd with dry Sand, which being preſerv'd from Wet, will afford a great deal of Pleaſure, when other Flowers are not to be procur'd.

The ninth and tenth Sorts are Biennial Plants. Theſe ſeldom continue after they have flower'd and produc'd Seeds. They may be ſown in the Spring upon a warm and dry Border; and when the Plants are come up pretty ſtrong, they may be tranſplanted out either into Pots or in warm Borders, allowing them at leaſt eight or ten Inches Room; for when they grow ſtrong, they ſhoot out many Branches from their Sides, and produce Bunches of dry Flowers like the other Plants of this kind, which being preſerv'd, do add to the Variety.

But theſe Plants while freſh, do emit a violent ſtrong Smell upon the leaſt Touch, for which they have been by many People rejected. They will endure our ordinary Winters in the open Air, if planted in a dry Soil; but in ſevere Cold, are apt to be demoliſh'd.

The eleventh Sort is one of the moſt beautiful of all this Tribe, producing large Bunches of bright Yellow-colour'd Flowers. This is preſerv'd in *Portugal* and *Spain* for adorning their Places of Worſhip in the Winter-ſeaſon, as alſo for the Ladies to adorn their Heads; for which Purpoſes it is preferable to any of the flowery Tribe.

This Plant ſeldom produces Seeds in *England*, but is propagated by planting Cuttings in the Summer-ſeaſon, which muſt be ſet in Pots of light Earth, and plung'd into a moderate Hot-bed, to facilitate their ſtriking root; then you muſt put each Plant into a ſeparate Pot fill'd with the like freſh Earth, and during the Summer-ſeaſon you may expoſe them with *Oranges*, *Myrtles*, &c. but in Winter they muſt be put either under a Hot-bed Frame, or into an airy Green-houſe, placing them near the Windows, that they may enjoy the free Air, whenever the Weather will permit the Glaſſes to be open'd; for if they are crowded amongſt other Plants, they are apt to draw, and their under Branches and Leaves will rot and decay: It muſt alſo have frequent, but gentle Waterings. This produces its Flowers in *May*, which when fully grown, ſhou'd be cut, and preſerv'd in clean white Papers, and kept from the Air, which greatly diminiſhes their Beauty: And this cutting off the Flowers will cauſe them to puſh out many Side-ſhoots whereby the Plant may be increas'd.

The twelfth Sort grows to be a very large Tree, where it hath the Advantage of a warm Climate, that it may be planted in the full Ground: And here in *England* there are ſeveral Trees of pretty large Growth: We have ſome in the Phyſick Garden, which are upward of twelve Feet high, and have conſiderable Stems, and fine regular Heads, to which they may be eaſily train'd, provided Care be taken in their Direction while young.

This is propagated by planting Cuttings, as was directed for the former Sort, and requires to have a freſh light Soil, and frequent Waterings: In Winter it muſt be hous'd with Bays and other hardy Kinds of Ever-greens, where it may have free open Air in mild Weather. I have ſometimes known Plants of this Kind endure abroad in moderate Winters; but in ſevere Cold they never eſcape.

The 14th, 15th, 16th, 17th and 18th Sorts are all propagated by Cuttings, as was before directed. Theſe may be train'd up to Shrubs with regular Stems, and will grow to the Height of ſix or ſeven Feet: They are pretty hardy, and require only to be ſecur'd from our ſevere Froſts, and muſt have free open Air and frequent Waterings in mild Weather. Theſe are all pretty Varieties in Collections of Exotick Plants; and altho' ſome of the Flowers have no great Beauty in them, yet they are worth preſerving, for the ſake of Variety.

The 19th Sort is very common in the *Engliſh* Gardens, and has been taken for the *Stœchas citrina* of the Diſpenſatory, by many good Botaniſts, but is very different from it. This will riſe to the Height of three Feet, and become ſhrubby; it is hardy, and may be eaſily propagated by planting Cuttings of it, in *April*, in a ſhady Border, obſerving to refreſh them with Water, and keep them clear from Weeds. Theſe Cuttings will have made good Roots in about two Months; when they may be taken up with a Ball of Earth to their Roots, and tranſplanted where they are deſigned to remain. Theſe Plants may be kept in a regular Form, by pruning off their Side Branches, and ſupporting them with Stakes: but the Shoots muſt not be ſhortned in the Spring or Summer Months, for that will prevent their flowering.

The thirteen following Sorts are more rare in *England* than the 19th, and are of humbler Growth. Theſe may be propagated by Slips, which ſhould be planted in Pots, filled with light rich Earth, and then plunged into a very moderate Hot-bed of Tanners-bark; obſerving to ſcreen them from the Sun until they have taken Root, when they ſhould be inured t bear the open Air by degrees. In Summer theſe Plants ſhoul be placed abroad in a ſheltered Situation, obſerving to wate them duly in dry Weather: but in Winter they ſhould be placed under a Hot-bed Frame, where they muſt have as muc free Air as poſſible in mild Weather; for they are pretty hardy, and only require to be protected from ſevere Froſt. Th following Spring ſome of the Plants may be ſhaken out of th Pots, and planted in a warm Border near the Shelter of Wall; where they will produce their Flowers, and may abid ſeveral Years, provided the Winters do not prove very ſever

However, it will be proper to keep a Plant or two of each Kind in Pots, which may be ſheltered in Winter, ſo that if thoſe which were planted abroad ſhould be deſtroyed, theſe may be preſerved to maintain the Sorts.

The ſix laſt-mentioned Kinds, are ſomewhat tenderer than the former; ſo require a little more Care to preſerve them in Winter. Theſe may be propagated by Cuttings, in the ſame manner as the former; which when rooted muſt be planted in Pots, filled with light freſh Earth, and placed in a ſhady Situation until they have taken new Root; after which time, they may be expoſed with other hardy exotic Plants, in a warm Situation, where they may be defended from ſtrong Winds; in which Place they may remain until the Middle of October, at which time they ſhould be removed into an open airy Green-houſe; where they ſhould have as much free Air as poſſible in mild Weather, to prevent their making long weak Shoots; which will not only render them unſightly, but alſo cauſe them to flower ſparingly. Theſe Plants require to be frequently watered in Winter, when the Weather is mild; which may ſoon be diſcovered by the hanging of their Leaves; but at this Seaſon they muſt not have ſo large Quantities of Water as in Summer, for that will ſometimes rot them.

Some of theſe Sorts may be trained up to the Height of three or four Feet, and if they are rightly managed, may be reduced to regular Heads; whereby they will become very ornamental in a good Garden: for as they continue to produce their Flowers through moſt of the ſummer Months, and many of them produce Flowers late in Autumn, which will continue in Beauty moſt part of the winter Seaſon; ſo they afford an agreeable Variety at a Seaſon when other Flowers are very ſcarce. Beſides, the different Appearance which theſe Plants have from their hoary and woolly Leaves, makes an agreeable Diverſity amongſt other Plants in the Green-houſe, when they are wholly diveſted of their Flowers.

The Flowers of all theſe Sorts of Plants, if they are gathered when in Perfection, and laid in a dry Place where they may be kept from Duſt and Air, will continue freſh and in Beauty for ſeveral Years; ſo that from the ſeveral Varieties of theſe Flowers, a Baſon or Flower-pot may be furniſhed in Winter, when few other Flowers can be procured, which will have a pretty Effect, in Rooms or Halls; but the Stalks of theſe Flowers muſt not be placed in Water, nor ſhould any Moiſture come to their Flowers, for that will decay them.

ELM. *Vide* Ulmus.

EMERUS; [This Name was given it by *Theophraſtus*, and reſtor'd by *Cæſalpinus*: It is by others call'd *Colutea*] Scorpion Sena, *vulgo*.

The *Characters* are;

It hath Leaves like thoſe of the Colutea; *the Flowers are papilionaceous; the Pods are ſlender, and contain two or three Cylindrical-ſhap'd Seeds in each.*

The *Species* are;

1. EMERUS. *Cæſalp.* Scorpion Sena, *vulgo*.
2. EMERUS *minor. Tourn.* The leſſer Scorpion Sena.

The firſt of theſe Shrubs is very common in all the Nurſeries near *London*, but the ſecond is at preſent in very few Gardens; theſe are both of them extreme fine Flowering Shrubs, and are great Ornaments to ſmaller Wilderneſs Quarters of Shrubs which are of equal Growth. The firſt will riſe to the Height of ſeven or eight Feet, and may be reduced to a regular Figure, if proper Care be taken while they are young. The ſecond ſeldom riſes above two or three Feet high, but may be train'd into a handſome Figure. Theſe Shrubs continue Flowering through the greateſt Part of the Summer; therefore the beſt Seaſon to prune them, in order to reduce them into Shape, is about the Middle of *September*, ſoon after they have done flowering; for if you cut them in Summer, it will prevent their Flowering in Autumn, unleſs it be done in *May*, which will deſtroy the firſt Crop of Flowers, and prevent their producing Seeds.

Theſe Shrubs are eaſily propagated by ſowing their Seeds (which they commonly produce in great Plenty) in *March* upon a Bed of light ſandy Earth, obſerving to keep the Bed clear from Weeds; and in very dry Weather you muſt often refreſh the Bed with Water, which ſhould be given carefully, leſt the Seeds ſhould be waſh'd out of the Ground by haſty watering. When the Plants are come up, you muſt continue the ſame Care; and the *Michaelmas* following (if your Plants have thriven well) you may draw out the largeſt, which may be tranſplanted into a Nurſery, at three Feet Diſtance Row from Row, and one Foot aſunder in the Rows; this will give Room to thoſe Plants which are left to grow in the Seed-bed, in which Place they may remain another Year, when they will alſo be fit to tranſplant into a Nurſery, where they ſhould be train'd up in the manner you deſign them to grow, either in round Heads, or in rude Plants: In two or three Years more they will be fit to plant out, where they are to remain for good; in doing of which, you ſhould be careful, in taking them up, not to break or wound the Roots: nor ſhould they remain too long in the Nurſery before they are tranſplanted; for they are ſubject to ſhoot downright Roots, which, when cut off, oft-times proves the Death of the Tree. In all other reſpects it muſt be treated like other Flowering Shrubs, amongſt which this is commonly ſold at the Nurſeries. It delights in a dry Soil; and may alſo be propagated by laying down the tender Branches, which will take Root in about a Year's Time, and may then be tranſplanted into a Nurſery, and managed in the ſame manner as the Seedlings.

EMPETRUM; [Ἔμπετρον, of ἐν *in*, and πέτρα, Gr. a *Rock* or *Stone*, becauſe this Tree grows in Stony Places] Black-berry'd Heath.

The *Characters* are;

It hath Leaves like thoſe of the Heath; *the Flowers are Male and Female, which grow in different Parts of the ſame Plant; the Male Flowers have no Petals; the Female Flowers are ſucceeded by* Black-berries, *in each of which are contain'd three or four hard Seeds.*

We have but one *Species* of this Plant in *England*, which is;

EMPETRUM *montanum, fructu nigro. Tourn.* Black-berry'd Heath, Crow-berries, or Crake-berries.

This little Shrub grows wild upon the Mountains of *Staffordſhire*, *Derbyſhire*, and *Yorkſhire*, and is ſeldom propagated in Gardens, unleſs for Variety-ſake: but it may be cultivated in ſhady Places where the Soil is ſtiff in Gardens, and will thrive very well; and may be propagated by ſowing the Seeds, ſoon after they are ripe, in a moiſt ſhady Place, which ſhould be kept clear from Weeds, and ſuffer'd to remain undiſturb'd until the ſecond Year, at which time the Plants will come up, and the Year following may be tranſplanted where they are to remain, and will require no farther Care than to clear them from Weeds.

EMUSCATION, the Clearing a Tree of Moſs. *Lat.*

ENUCLEATION; a Taking-out the Nut or Kernel of any Fruit. *Lat.*

ENULA CAMPANA. *Vide* Helenium.

EPHEDRA, Shrubby Horſe-tail, *vulgo*.

The *Characters* are;

It hath an apetalous Flower, conſiſting of many Stamina, which are for the moſt part barren, for the Embryos grow on different Parts of the ſame Plant, or on other Plants which have no conſpicuous Flowers: Theſe Embryos afterwards become ſoft Berries, in which are contained many oblong Seeds.

The *Species* are;

1. EPHEDRA *maritima major. Tourn.* Greater Sea Horſe-tail.
2. EPHEDRA *maritima minor. Tourn.* Leſſer Sea Horſe-tail.
3. EPHEDRA *ſive Anabaſis. Bellon. Tourn.* Climbing Sea Horſe-tail.
4. EPHEDRA *Hiſpanica arboreſcens, tenuiſſimis & denſiſſimis foliis. Tourn. Spaniſh* Tree-like Horſe-tail, with narrow cluſtery Leaves.
5. EPHEDRA *Cretica, tenuioribus & rarioribus flagellis. Tourn. Candy* Horſe-tail, with narrower and fewer Branches.
6. EPHEDRA *orientalis procerior, flagellis durioribus, & mediæ craſſitiei. Tourn.* Taller Eaſtern Horſe-tail, with harder and thicker Branches.

The firſt of theſe Plants is pretty common in the *Engliſh* Gardens, but the others are at preſent pretty rare in this Country; and are only cultivated in botanic Gardens for the ſake of Variety, there being little Beauty in theſe Plants, nor are they uſed in Medicine.

They may be propagated by Off-ſets, which they ſend forth in great Plenty; for they creep under Ground by their Roots, and ſend forth Suckers, which may be taken off to tranſplant in the Spring. They love a pretty moiſt ſtrong Soil, and will endure the Cold of our ordinary Winters very well in the open Air. The firſt, fourth, and ſixth Sorts will riſe to the Height of three or four Feet, provided their Roots are kept pretty clear from Suckers; otherwiſe they will ſpread very far, and ſend forth great plenty of Suckers, which will prevent their riſing in Height. Some of theſe Plants were formerly preſerved in Pots, and were houſed in Winter, but by later Experience they are found to thrive better in the full Ground.

EPHEMERON; ['Εφήμερον, of ἐπὶ, and ἡμέρα, Gr. a *Day*, becauſe the Flowers of this Plant ſeldom continue longer blown than one Day] *Virginian* Spider-wort, *vulgo*.

The *Characters* are;

The Cup of the Flower conſiſts of three Leaves; the Flower alſo hath three Petals, which expand in form of a Roſe, *and hath three Stamina (or Threads) which ſurround the Ovary; the Fruit is oblong, and divided into three Cells, which are fill'd with Seeds like a Grain of Wheat.*

The *Species* are;

1. EPHEMERUM *Virginianum, flore cœruleo majori. Tourn.* *Virginian* Spider-wort, with a large blue Flower.
2. EPHEMERUM *Virginianum, flore purpureo majori. Tourn.* *Virginian* Spider-wort, with a large purple Flower.
3. EPHERUM *Virginianum, flore azureo majori. Tourn.* *Virginian* Spider-wort, with a large azure Flower, *commonly called*, the *Savoy* Spider-wort.
4. EPHEMERUM *Virginianum, flore cœruleo minore. Tourn.* *Virginian* Spider-wort, with a ſmall blue Flower, *commonly called*, *John Tradeſcant*'s Spider-wort.
4. EPHEMERUM *Virginianum, flore albo. Tourn.* *Virginian* Spider-wort, with a white Flower.
6. EPHEMERUM *Virginianum, flore purpureo minore. Tourn.* *Virginian* Spider-wort, with a ſmall purple Flower.

The ſeveral Varieties of this Plant are eaſily propagated, by parting their Roots either in Spring or Autumn; and ſhould be planted in a moiſt Soil, where they will thrive and increaſe exceedingly, and are extreme hardy, enduring our ſevereſt Cold in the open Air.

Theſe are very proper for large Borders, where they may have Room to grow; but if they are planted in ſmall Borders, they ſhould be parted into ſmall Heads every Year, otherwiſe they will grow too large for ſuch Places. They may be planted in ſhady Borders, where their Flowers will continue longer than if expos'd too much to the great Heat of the Sun. This Flower ſeldom ſurvives the Day, but is ſucceeded by new ones daily, for ſeveral Months; ſo that it may deſerve a Place for the long Continuance of its Flowering.

EPIMEDIUM; ['Επιμήδιον, of ἐπὶ, and μήδιον, q. d. *over-and-above* Three-leav'd, as tho' the Great Trefoil, becauſe the Leaves of this Plant are large, and always by Threes] Barren-wort.

The *Characters* are;

The Stalks are divided into three Branches, each ſingle Branch ſuſtaining three Leaves, which are ſhap'd ſomewhat like Ivy; *the Calyx conſiſts of four Leaves; the Flower conſiſts of four Petals, which are hollow, and expand in form of a Croſs; the Pointal of the Flower becomes a Pod with one Cell, having two Valves, in which are contain'd round flat Seeds.*

We have but one *Species* of this Plant at preſent in *England*, which is,

EPIMEDIUM. *C. B.* Barren-wort.

This is a Plant of no great Beauty, yet, for Diverſity, may have a Place in a Garden: It is eaſily propagated, by parting the Roots (which increaſe very faſt under-ground) either in the Spring or Autumn, and ſhould be planted in a moiſt Soil, and a ſhady Situation. This Plant produces its Flowers in *May*, but ſeldom ripens Seeds with us: This may be owing to its ſpreading Roots, which exhauſt the Nouriſhment from the Flowers and Fruit, and might, perhaps, be procur'd, by confining the Roots to a Pot. The Roots thereof, if planted in a good Border, ſhould be every Year reduc'd, ſo as to keep it within Bounds; otherwiſe it will overſpread the whole Spot, and deſtroy whatever Plants grow near it.

EPIPHYLOSPERMOUS PLANTS [of *'ἐπὶ, upon*, φύλλον, *a Leaf*, and Σπέρμα, *Gr. Seed*] ſuch Plants as bear their Seeds on the Back of their Leaves; the ſame as *Capillaries*.

EQUINOCTIAL, ÆQUINOCTIAL, [of *Æquus*, Equal, and *Nox*, *Lat.* Night] a great and immoveable Circle of the Sphere, under which the *Equator* moves in its Diurnal Motion.

The *Equinoctial*, or *Equinoctial-Line*, is ordinarily confounded with the *Equator*: But there is a Difference; the *Equator* being moveable, and the *Equinoctial* immoveable; and the *Equator* drawn about the Convex Surface of the Sphere; but the *Equinoctial*, on the Concave Surface of the *Magnus Orbis*.

The *Equinoctial* is conceiv'd, by ſuppoſing a Semi-diameter of the Sphere, produc'd thro' a Point of the *Equator*, and there deſcribing a Circle on the immoveable Surface of the *Primum Mobile*, by the Rotation of the Sphere about its Axis.

Whenever the *Sun* comes to this Circle, in his Progreſs thro' the Eclíptick, it makes Equal Day and Night all around the Globe; as then ariſing due *Eaſt*, and ſetting due *Weſt*, which he never does at any other Times of the Year.

The People who live under this Circle have their Days and Nights conſtantly Equal; and the *Sun* is in their Zenith at Noon, and caſts no Shadow.

EQUINOXES, are the Times when the *Sun* enters into the Equinoctial Points, which are the two Points where the *Equator* and *Ecliptick* interſect each other; the one being in the firſt Point of *Aries*, call'd the *Vernal Equinox*; and the other in the firſt Point of *Libra*, call'd the *Autumnal Equinox*.

So the *Equinoxes* happen when the *Sun* is in the *Equinoctial* Circle, when, of Conſequence, the Days are equal to the Nights throughout the World; which is the Caſe twice a Year, *viz.* about the 10th of *March*, and the 12th of *September*; the firſt of which is the *Vernal*, and the ſecond the *Autumnal Equinox*.

EQUISETUM, [of *Equus*, an *Horſe*, and *Seta* a *Briſtle*, becauſe the Leaves and Branches repreſent the Briſtles or Hair of a Horſe's Main or Tail. It is by the *Greeks* call'd 'Ιππουρις, of ῞Ιππος, an *Horſe*, and Οὐρὰ, a *Tail*; and *Hippoſeta*, of ῞Ιππ, and *Seta*] Horſe-Tail.

There are ſeveral *Species* of this Plant, which are found in *England*, on the Sides of Ditches, or in ſhady Woods: But as they are Plants which are never cultivated in Gardens, ſo I ſhall paſs them over in this Place.

ERANTHEMUM. *Vide* Adonis.

ERICA ['Ερεική, of 'ερείκω, or 'ερίκω, Gr. to *break*, becauſ this Plant is ſaid to have the Virtue of Breaking the Stone in the Bladder] Heath.

The *Characters* are;

It is a Shrub of low Stature; the Leaves are ſmall, and abid green all the Year; the Flower conſiſts of one Leaf, is naked and for the moſt part ſhap'd like a Pitcher; the Ovary, (which i produc'd in the Bottom of the Flower) becomes a roundiſh Fruit which is divided into four Cells, in which are contain'd man ſmall Seeds.

The *Species* are;

1. ERICA *vulgaris glabra. C. B.* Common ſmoot Heath.
2. ERICA *vulgaris hirſuta. C. B.* Common rough-leav' Heath.
3. ERICA *tenuifolia. Ger.* Fine narrow-leav'd Heath.
4. ERICA *vulgaris, flore albo. C. B.* Common Heath with a white Flower.
5. ERICA *Brabantica, folio coridis, hirſuto quaterno. J.* *Low-Dutch* Heath.
6. ERICA *foliis coridis, multiflora. J. B.* Fir-leav'd Heat with many Flowers.
7. ERICA *Cantabrica, flore maximo, foliis myrti, ſubtus i canis. Tourn.* Hoary Myrtle-leav'd Heath, with a lar Flower.

Theſe Plants grow wild upon barren uncultivated Places, divers Parts of *England*: but notwithſtanding their Commo neſs, yet they deſerve a Place in ſmall Quarters of humb flowering Shrubs, where, by the Beauty and long Continuan of their Flowers, together with the Diverſity of their Leav they afford a very agreeable Proſpect.

Theſe are ſeldom propagated in Gardens, and ſo not to had from the Nurſeries; but may be taken up, with a Ball Earth to their Roots, from the natural Places of their Grow either in Spring or Autumn, and may be tranſplanted into

Gard

Garden. The Soil where they are planted ſhould not be dung'd; nor ſhould you beſtow any other Culture on them, than clearing them from Weeds; for the leſs the Ground is dug, the better theſe will thrive: And they commonly ſhoot their Roots near the Surface, which, in digging, are ſubject to be hurt, whereby the Plant is often deſtroy'd: Theſe may alſo be propagated by Seeds; but this being a tedious Method, the other is much preferable to it.

ERICA BACCIFERA. *Vide* Empetrum.

ERIGERON. *Vide* Senecio.

ERUCA, [is ſo call'd of ἐρύειν, to *attract*, or of *crudere* to *gnaw out*, becauſe this Plant has a hot biting Savour.] Rocket.

The *Characters* are;

The Flower conſiſts of four Leaves, which expand in Form of a Croſs; the Pointal becomes a Pod, which is divided into two Cells by an intermediate Partition, to which the Valves adhere on both Sides; theſe Cells are full of roundiſh Seeds; to which may be added, The whole Plant hath a peculiar fœtid Smell.

The *Species* are;

1. ERUCA *ſylveſtris major lutea, caule aſpero. C. B.* Greater wild Rocket, with a rough Stalk, and yellow Flower.

2. ERUCA *tenuifolia perennis, flore luteo. J. B.* Narrow-leav'd perennial Rocket, with a yellow Flower.

3. ERUCA *bellidis folio. Mor. Hiſt.* Daizy-leav'd Rocket.

4. ERUCA *tanacetifolia. H. R. Par.* Tanſy-leav'd Rocket.

5. ERUCA *major ſativa annua, flore albo ſtriato. C. B.* Great Garden Rocket, with a white ſtrip'd Flower.

6. ERUCA *ſativa, foliis magis diſſectis. Hort. Edin.* Garden Rocket, with deeply-cut Leaves.

The four firſt Sorts are Varieties which are preſerv'd in curious Botanick Gardens, but are Plants of no great Beauty or Uſe: The firſt is very common upon dry Banks and old Walls in divers Parts of *England*.

The fifth Sort was formerly very much cultivated in Gardens as a Sallad-Herb, but at preſent is very little us'd.

The ſixth is a Variety of the fifth, from which it differs in having the Leaves deeply cut or jagged.

Theſe may be all propagated by ſowing their Seeds in the Spring on a Bed of light Earth, where they will ſoon come up; and being Plants of quick Growth, will be large enough for Uſe in a ſhort Time: for if they are ſuffer'd to grow large, they become too ſtrong to be eaten in Sallads. Some of the Plants may be left for Seeds, which they will produce in great Plenty the ſame Summer.

ERUCAGO, [ſo call'd of *Eruca* a *Rocket*, becauſe this Plant reſembles the *wild Rocket.*] Corn-Rocket.

The *Characters* are;

The Flower conſiſts of four Leaves, which expand in Form of a Croſs; the Pointal becomes a four-corner'd Fruit, reſembling a creſted Club, which is for the moſt part divided into four Cells, in which are contain'd roundiſh Seeds which have a Beak.

We have but one *Species* of this Plant, which is,

ERUCAGO *ſegetum. Tourn.* Corn-Rocket.

This Plant grows wild in the warm Parts of *France* and *Spain*, and is preſerv'd, for the ſake of Variety, in curious Botanick Gardens. It may be propagated in like manner as the *Rocket*; but being a Plant of no Beauty or Uſe, is hardly worth cultivating.

ERVUM, [of ἐρέπτω to *eat*, and Βοῦς, Gr. an *Ox*, becauſe this Herb is eaten by Oxen.] Jointed podded bitter Vetch.

The *Characters* are;

It hath a papilionaceous Flower, out of whoſe Empalement riſes the Pointal, which becomes a jointed Pod, undulated on both Sides, and in a manner knotted, which is full of roundiſh Seeds: To which may be added, The Leaves grow by Pairs on a Mid-rib.

The *Species* are;

1. ERVUM *verum Camer.* The true Ervum of *Camerarius*. This is alſo call'd *Orobus ſiliquis articulatis*. And the Seeds of this are ſometimes uſed in Medicine.

2. ERVUM *ſemine minore. Tourn.* Small-ſeeded Ervum.

3. ERVUM *ſemine obtuſo triangulo. Tourn.* Ervum with an obtuſe triangular Seed.

4. ERVUM *Orientale alopecuroides perenne, fructu longiſſimo. T. Cor. Oriental* perennial Ervum, with a very long Fruit.

Theſe Plants are very common in the Fields in warmer Countries, but are preſerv'd in curious Botanick Gardens for Variety. They may be propagated in the ſame manner as Peas, but require a warm Soil, and an open Situation, otherwiſe they will not ripen their Seeds with us. In the hotter Countries they uſe them for Food, but with us they are of little Uſe.

The fourth Sort is an abiding Plant; the Roots will continue ſeveral Years, provided they are not tranſplanted, and will produce long Spikes of Flowers every Year; but the Plant dies to the Root every Autumn: this is alſo propagated by Seeds, which ſhould be ſown where the Plants are to remain.

ERYNGIUM, ['Ερύγγιον, Gr. *Goat's-beard*, becauſe the Heads of this Plant, before the Stalks and Leaves are grown, reſemble the Beard of a Goat.] Sea-Holly or Eryngo.

The *Characters* are;

The Leaves are produc'd alternately on the Branches; the Flowers conſiſt of five Leaves, which are plac'd orbicularly, and are reflex'd back to the Center of the Flower; the Empalement afterwards becomes a Fruit, compos'd of two Seeds, which are ſometimes foliated, and ſometimes plain; to which may be added, The Flowers are collected into a ſquamoſe Head, which is prickly.

The *Species* are;

1. ERYNGIUM *maritimum. C. B.* Sea-Holly or Eryngo.

2. ERYNGIUM *vulgare. C. B.* Common Eryngo.

3. ERYNGIUM *latifolium planum. C. B.* Broad-leav'd plain Eryngo.

4. ERYNGIUM *latifolium planum, caule ex viridi palleſcente, flore albo. C. B.* Broad-leav'd plain Eryngo, with a greeniſh white Stalk, and a white Flower.

5. ERYNGIUM *montanum amethyſtinum. C. B.* Purple Violet-coloured Mountain Eryngo.

6. ERYNGIUM *Alpinum amethyſtinum, capitulo majore palleſcente. Tourn. Alpine* Eryngo, with a large pale-colour'd Head.

7. ERYNGIUM *Orientale, foliis trifidis. T. Cor. Oriental* Eryngo, with trifid Leaves.

The firſt of theſe Species grows in great Plenty on the ſandy and gravelly Shores in divers Parts of *England*, the Roots of which are candy'd, and ſent to *London* for medicinal Uſes, and is the true *Eryngo*.

The fifth and ſixth Sorts are beautiful Plants in Gardens; tho' at preſent they are very uncommon in *England*, but do deſerve a Place in the moſt curious Flower-Gardens.

The other Species are preſerv'd in very fine Gardens of Plants, for the ſake of Variety, but have no great Beauty in them.

Theſe Plants may all be propagated by parting of their Roots, or ſowing their Seeds: The firſt being the moſt expeditious Method, is chiefly us'd; this muſt be done in *February*, or the Beginning of *March*, before the Roots have ſhot out their Leaves. The Soil in which theſe delight moſt, is Gravel, or Sand: but if it be very dry, they will require to be often watered in Summer, eſpecially the firſt Sort. The ſecond Year after planting they will produce Flowers, but it is very rare that they do it the firſt; therefore it is the beſt Way to let the Roots remain unremov'd for three or four Years, by which Method your Flowers will be ſtronger, and in greater Plenty. Theſe Plants commonly produce good Seeds, if the Seaſon is not over-wet, which is ſometimes apt to rot their Heads before the Seeds are ripe.

If you would propagate theſe Plants by Seed, it ſhould be ſown ſoon after it is ripe; for if it be kept until Spring before it is ſown, the Plants ſeldom ariſe until the ſucceeding Year. When they are come up, they ſhould be carefully weeded; and in very dry Weather they ſhould be refreſh'd with Water two or three times a Week, which will greatly promote their Growth: In this Place they ſhould continue until the ſucceeding Spring, at which Time they ſhould be tranſplanted out to the Places where they are to remain; for they do not care to be often remov'd: The third Year after ſowing they commonly produce their Flowers, and continue for many Years ſo to do, provided they are not diſturb'd.

The firſt and ſecond Sorts creep very far under-ground, by which they greatly increaſe: but their Roots are of little Uſe, for they ſeldom grow to any conſiderable Size in a Garden.

ERYSIMUM, [Ἐρύσιμον, of ἐρύω, Gr. to *draw out*, becauſe this Plant, by means of its hot Quality, has the Virtue of drawing any thing out of the Body in which it lies hid.] Hedge-Muſtard.

The *Characters* are;

The Flower conſiſts of four Leaves, which expand in Form of a Croſs; the Pointal becomes a long ſlender bivalve Pod, which is divided into two Cells by an intermediate Partition, in which are contain'd many round Seeds.

The *Species* are;

1. ERYSIMUM *vulgare. C. B.* Common Hedge-Muſtard.
2. ERYSIMUM *latifolium majus glabrum. C. B.* Great broad-leav'd ſmooth Hedge-Muſtard.
3. ERYSIMUM *polyceratium vel corniculatum. C. B.* Hedge-Muſtard, with many crooked Pods.
4. ERYSIMUM *anguſtifolium majus. C. B.* Great narrow-leav'd Hedge-Muſtard.
5. ERYSIMUM *Sophia dictum. Raii Syn. Ed.* 3. Flixweed.

There are ſeveral other Varieties of this Plant, which are preſerv'd in Botanick Gardens: but as they are Plants of little Uſe or Beauty, ſo they are ſeldom propagated in any other Garden.

The firſt, ſecond, and fifth Sorts are very common upon dry Banks in divers Parts of *England:* but the third and fourth Sorts are Natives of a warmer Country.

Theſe may all be propagated by ſowing their Seeds ſoon after they are ripe, which will come up in a ſhort Time, and will ſtand Abroad, and endure the Winter's Cold very well; and early in the Spring they will ſhoot up to Flower, and produce ripe Seeds in *June* or *July:* but if they are ſown in the Spring, the Seeds ſeldom come up ſo well; nor do the Plants arrive at half the Strength of thoſe ſown in Autumn; for when the Heat comes on, they ſoon run up to Flower, and thereby produce not half the Quantity of Seeds.

The firſt and fifth Sorts are us'd in Medicine; but particularly the fifth, the Seed of which is by many People ſaid to be an extraordinary Medicine for the Stone and Gravel.

ESCHYNOMENOUS, ÆSCHYNOMENOUS PLANTS, [Αἰσχυνόμενοι, of αἰσχύνομαι, Gr. to be *aſhamed.*] The Senſitive Plants, which, when one comes near them, or touches them, will ſhrink in, or let their Leaves fall down.

ESCULENT PLANTS, [of *Eſculentus*, Lat. *Eatable.*] Such Plants, or the Roots of them, that may be eaten, as *Beets*, *Carrots*, *Jeruſalem Artichokes*, *Leeks*, *Onions*, *Parſnips*, *Potatoes*, *Radiſhes*, *Horſe-radiſh*, *Scorzonera*, &c.

ESPALIERS.

Are either Rows of Trees planted about a whole Garden or Plantation, or in Hedges, ſo as to incloſe Quarters or ſeparate Parts of a Garden, which are train'd up flat in a cloſe Hedge, for the Defence of tender Plants againſt the Violence and Injury of Wind and Weather. See *Hedges*.

The moſt commonly receiv'd Notion of *Eſpaliers*, are Hedges of Fruit-Trees which are train'd up regularly to a Lattice of Wood-work, form'd either of Aſh Poles, or ſquare long Timbers cut out of Fir, &c. and it is of this Sort of *Eſpalier* that I ſhall treat in this Place.

Eſpaliers of Fruit-Trees are commonly planted to ſurround the Quarters of a Kitchen-Garden, for which Purpoſe they are of admirable Uſe and Beauty: for by laying out the Walks of this Garden regularly, which are bounded on each Side by theſe Hedges, when they are handſomely managed, they have a wonderful Effect in ſheltering the Kitchen-Plants in the Quarters, and alſo ſcreening them from the Sight of Perſons in the Walks; ſo that a Kitchen-Garden well laid out in this manner, and regularly manag'd, will be equal to the fineſt Paterre for Beauty.

The Trees chiefly planted for *Eſpaliers*, are *Apples*, *Pears*, and ſome *Plums*; but the two former are moſtly uſed: ſome plant *Eſpaliers* of *Apples* grafted upon *Paradiſe*-Stocks; but theſe being of a ſhort Duration, are not ſo proper for this Purpoſe; therefore I ſhould rather adviſe the having them upon *Crab*-Stocks, or (if in ſmaller Gardens, where the Trees cannot be allow'd to grow ſo high) upon *Codlin*-Stocks, which will cauſe them to bear ſooner, and prevent their growing too luxurious.

In chuſing the Trees for an *Eſpalier*, endeavour, as near as poſſible, to plant the ſeveral Sorts which are nearly of the ſame Growth in one Line, that the *Eſpalier* may be the more regular, and of an equal Height, which greatly adds to their Beauty; for if you plant Trees which ſhoot very unequally in the ſame Line, it will be impoſſible to make the *Eſpalier* regular: beſides, the Diſtance the Trees are to be planted muſt be directed hereby; for ſome Trees, *viz.* thoſe of a large Growth, ſhould be planted twenty or twenty-five Feet aſunder, whereas thoſe of ſmaller Growth need not be above ſixteen or eighteen Feet Diſtance from each other.

The Width of the Walks between theſe large *Eſpaliers* ſhould (in a large Garden) be fourteen or ſixteen Feet at leaſt; and if they are deſign'd to be carry'd up pretty high, the Diſtance ſhould be greater, that each Side may receive the Advantage of the Sun and Air; which is abſolutely neceſſary, if you would have the Fruit well-taſted. And if your Ground is ſo ſituated, that you are at full Liberty which Way to make the *Eſpaliers*, I ſhould adviſe the placing the Lines from the Eaſt a little inclining to the South, and toward the Weſt a little inclining to the North, that the Sun may ſhine between the Rows in the Morning and Evening when it is low; for in the Middle of the Day, when the Sun is advanced far above the Horizon, it will ſhine over the Tops of the *Eſpaliers*, and reach the Surface of the Earth about their Roots; which is a Matter of more Conſequence than many People are aware of.

The Sorts of *Apples* proper for *Eſpaliers*, are the *Golden Pippen*, *Nonpareil*, *Rennette Griſe*, *Aromatick Pippen*, *Holland Pippen*, *French Pippen*, *Wheeler's Ruſſet*, *Pile's Ruſſet*, with ſeveral others. The Seaſon for Planting, and the Method of Pruning and Training theſe Trees, you'll ſee under the Articles of *Apples* and *Pruning*.

The Sorts of *Pears* proper for an *Eſpalier*, are Summer and Autumn Fruits; for Winter *Pears* ſeldom ſucceed well in an *Eſpalier*. Theſe Trees, if deſign'd for a ſtrong moiſt Soil, ſhould be upon *Quince*-Stocks; but if for a dry Soil, upon Free-Stocks. Their Diſtance of Planting muſt alſo be regulated by the Growth of the Trees, which are more unequal in *Pears* than *Apples*, and ſhould therefore be more carefully examin'd before they are planted. As for thoſe *Pears* upon Free-Stocks, the Diſtance ſhould never be leſs than eighteen Feet for moderate growing Trees; but for vigorous Shooters, twenty-five Feet are little enough, eſpecially if the Soil be ſtrong, in which Caſe they ſhould be planted at a greater Diſtance. The particular Sorts of *Pears* I would recommend for an *Eſpalier*, are the *Jargonelle*, *Blanquete*, *Poire ſans Peau*, *Summer Boncretien*, *Hamden's Burgamot*, *Poire du Prince*, *Poire ſans Pepin*, *Beurre du Roy*, *St. Michael*, *Le Marquis*, *Monſieur John*, *Creſſane*, with many others of leſs Note. As to the Method of Planting, ſee the Article *Pear*; and for Pruning and Managing, ſee *Pruning*.

I ſhall now give Directions for making the *Eſpalier*, to which the Trees are to be train'd: But this I would not have done until the third Year after the Trees are planted; for while they are young, it will be ſufficient to drive a few ſhort Stakes into the Ground on each Side of the Trees, to which the Branches ſhould be faſten'd in a horizontal Poſition, as they are produced; which Stakes may be plac'd nearer, or at a farther Diſtance, according as the Shoots produc'd may require, and will be ſufficient for the three firſt Years; for ſhould you frame the *Eſpalier* the firſt Year the Trees are planted, the Poles would rot before the *Eſpalier* is cover'd. The cheapeſt Method to make theſe *Eſpaliers* is with *Aſh*-Poles, of which you ſhould have two Sorts; one of the largeſt Size, which contains thirteen Poles in a Bundle, and the othe Size thoſe of half a hundred: The firſt or largeſt Size Pole ſhould be cut about ſeven Feet and a half long; theſe are intended for Upright Stakes, and muſt be ſharpen'd at the large End, that they may with more Eaſe be driven into the Ground theſe ſhould be plac'd at a Foot Diſtance from each other in direct Line, and of an equal Height, about ſix Feet abov Ground; then you ſhould nail a Row of ſtrait ſlender Pol along upon the Tops of the upright Stakes, which will kee them exactly even, and continue to croſs the Stakes with th ſmaller Poles, and the Tops which were cut off from th larger ones, at about nine Inches Diſtance, Row from Ro from the Top to the Bottom of the Stakes. Theſe Rows Poles ſhould be faſten'd with Wire, and the largeſt End of th Poles ſhould be nail'd to the upright Stakes, which will ſecu t the *Eſpalier* almoſt as long as the Poles will endure: whereas, if your Faſtening is not ſtrong, the Poles will be continually diſplac'd with every ſtrong Wind.

When your *Eſpalier* is thus fram'd, you muſt faſten the Branches of the Trees thereto, either with ſmall Oſier Twigs, or ſome ſuch Binding, obſerving to train them in an horizontal Poſition, and at equal Diſtances; being careful not to croſs any of the Branches, nor to lay them in too thick: The Diſtance I would allow for the Branches of *Pears* and *Apples*, ſhould be proportion'd according to the Size of their Fruit; ſuch of them whoſe Fruit is large, as the *Summer Boncretien*, *Monſieur John*, and *Beurre du Roy Pears*, and the *Rennet Griſe*, *Holland Pippin*, *French Pippin*, and other large *Apples*, ſhould have their Branches ſix or eight Inches Diſtance at leaſt; and to thoſe of leſſer Growth, four or five Inches will be ſufficient. But for farther Directions, I ſhall refer to the Articles of the ſeveral Fruits, as alſo that of *Pruning*, where the Particulars will be ſufficiently explain'd.

But beſides this Sort of *Eſpalier* made with *Aſh*-Poles, there is another Sort that is by many People preferr'd, which is framed with ſquare Timbers cut to any Size, according to the Strength thereof, or the Expence the Owner is willing to go to; theſe, tho' they appear more ſightly, when well fixed and painted, yet are not of longer Duration than one of the former, provided it is well made, and the Poles are ſtrong which are ſet upright: nor do they anſwer the Purpoſe better, tho' they are vaſtly more expenſive; for the greateſt Beauty conſiſts in the diſpoſing the Branches of the Tree, which, eſpecially in Summer, when the Leaves are on, will intirely hide from the Sight the Frame of the *Eſpalier*: therefore all Expence in erecting theſe is needleſs, farther than making Proviſion to ſecure the Branches of the Trees in a regular Order.

Fruit-trees thus planted, and well managed, are much preferable to thoſe train'd up in any other Figure, upon ſeveral Accounts; as, *firſt*, theſe take up very little Room in a Garden, ſo as to be hurtful to the Plants which grow in the Quarters; and, *2dly*, the Fruit upon theſe are better taſted than thoſe which grow upon Dwarfs, the Sun and Air having freer Acceſs to every Part of the Tree, whereby the Dampneſs ariſing from the Ground is ſooner diſſipated; which is of ſingular Advantage to Fruit-trees, (as hath already been ſhewn.)

EVER-GREEN THORN. *Vide* Pyracantha.

EVERLASTING PEA. *Vide* Lathyrus.

EUONYMUS, [Εὐώνυμος, of εὐ, *good*, and ὄνομα, a *Name*, ſo call'd by way of Antiphraſis, becauſe it is hurtful to Animals.] The Spindle-tree, or Prickwood.

The *Characters* are;

It has four reddiſh Lines running along the Branches, which make them appear in ſome meaſure quadrangular: the Flowers, for the moſt part, conſiſt of four Leaves, which are ſucceeded by quadrangular Fruit, containing four red Seeds in each.

The *Species* are;

1. Euonymus *vulgaris, granis rubentibus. C. B.* The common Spindle-tree.

2. Euonymus *latifolius. C. B.* Broad-leav'd Spindle-tree.

3. Euonymus *Africanus, Lycii craſſioribus foliis, ſempervirens, capſula triloculari aſperata rubente. Boerh. Ind.* Ever-green African Spindle-tree, *commonly call'd* African Barberry.

4. Euonymus *Virginianus, pyracanthæ foliis, ſempervirens, capſula verrucarum inſtar aſperata rubente. Pluk. Phyt.* 115. f. 5. Virginian Ever-green Spindle-tree, with rough, warted, ed Seed-veſſels.

The firſt of theſe Species is very common in Hedges in di-ers Parts of *England*, where it ſeldom riſes to any conſider-ble Stature: but if planted amongſt other Trees in Wilder-eſs Quarters, may be train'd up ſo as to become a large hand-me Tree; and in the Autumn Seaſon, when the Fruit is pe, doth make a very handſome Shew. The Wood of this ree is uſed by the Inſtrument-makers, for Toothing of Or-ans and Virginal-Keys, Tooth-pickers, Spindles, and to ake Scures, *&c.* The Broad-leav'd Sort, tho' very common moſt Parts of *Europe*, yet is rarely to be found in *England*, cept in curious Collections of Trees and Shrubs. Theſe o Plants are very hardy, in reſpect to Cold, and may be opagated either by ſowing the Seeds, or laying down the anches: but the firſt being a tedious Method, is ſeldom ctiſed; for the Seeds remain in the Ground until the ſecond ear before the Plants come up, and afterwards make but little Progreſs during the three or four firſt Years, whereas thoſe raiſed by Layers will make handſome Trees in three or four Years Time.

The other two Sorts being Natives of a warm Country, will not endure the Cold of our Climate in the open Air, and muſt therefore be preſerved in a good Green-houſe in Winter. Theſe may be propagated by planting Cuttings any Time from *May* to *September*, which ſhould be ſet into Pots fill'd with freſh light Earth, and plung'd into a moderate Hot-bed, and carefully water'd and ſhaded until they have taken Root; after which, they may be tranſplanted each into a ſeparate Pot, and expoſed to the open Air till *September*, when they ſhould be removed into the Green-houſe, where, during the Winter Seaſon, they muſt have as much free open Air as the Weather will admit of, as alſo frequent, but gentle Waterings: in other reſpects they may be managed as *Orange-trees*, obſerving to ſhift the Plants into freſh Earth every Year.

The third Sort grows to be a Shrub of five or ſix Feet in Height, and will produce great Quantities of Fruit, which ripen in Winter, and make a very good Appearance in the Green-houſe at that Seaſon. This is the tendereſt Plant of them all.

The fourth Sort ariſes with us to the Height of ten or twelve Feet, and may be train'd up to a regular Head; and when grown to be large, will annually produce Flowers and Fruit; which, altho' they have no great Beauty, yet the Tree, for Variety, deſerves a Place in every good Collection of Plants. This is pretty hardy, and only requires to be ſhelter'd from extreme Froſts in Winter, and therefore ſhould be early expoſed to the open Air in Spring, and ſuffer'd to remain abroad in Autumn.

EUPATORIOPHALACRON, Naked-headed Hemp-agrimony.

The *Characters* are;

It is a corymbiferous Plant, which in ſome Species *have radiated Flowers, whoſe Florets are hermaphrodite, and the Half-florets are Female; but in other* Species *the Flowers are produced in a Diſk, and are for the moſt part hermaphrodite. The Ovaries have naked Heads, and are placed on a woolly Placenta; all theſe Parts are contained in a Flower-cup, which is divided into many Parts to the Placenta; to theſe Notes muſt be added, the Leaves growing oppoſite on the Branches.*

The *Species* are;

1. Eupatoriophalacron *balſaminæ fœminæ folio, flore albo diſcoide. Vaill.* Naked-headed Hemp-agrimony, with a female-balſam Leaf, and a white diſcous Flower.

2. Eupatoriophalacron *menthæ arvenſis folio. Vaill.* Naked-headed Hemp-agrimony, with a water-calaminth Leaf.

3. Eupatoriophalacron *foliis anguſtis, rarius dentatis, flore radiato. Vaill.* Naked-headed Hemp-agrimony, with narrow indented Leaves, and a radiated Flower.

4. Eupatoriophalacron *folio trinervi ſubrotundo, flore minore luteo radiato. Vaill.* Naked-headed Hemp-agrimony, with a roundiſh trinervated Leaf, and a ſmaller yellow radiated Flower.

5. Eupatoriophalacron *folio trinervi ſubrotundo, flore majore luteo radiato. Vaill.* Naked-headed Hemp-agrimony, with a roundiſh trinervated Leaf, and a larger yellow radiated Flower.

6. Eupatoriophalacron *perſicæ folio trinervi, flore minimo luteo diſcoide. Vaill.* Naked-headed Hemp-agrimony, with a trinervated Peach-leaf, and the leaſt yellow diſcous Flower.

7. Eupatoriophalacron *ſcrophulariæ folio trinervi. Vaill.* Naked-headed Hemp-agrimony, with a trinervated Figwort Leaf.

8. Eupatoriophalacron *ſcrophulariæ folio trinervi, caule alato. Vaill.* Naked-headed Hemp-agrimony, with a trinervated Figwort Leaf, and a winged Stalk.

9. Eupatoriophalacron *Indicum ſcrophulariæ folio, capitulo parvo radiis quinis ad baſin ornato, hiſpidis & glutinoſis. Act. Phil.* Indian Naked-headed Hemp-agrimony, with a Figwort Leaf, and a ſmall Head adorned with five Rays, which are prickly and glutinous.

10. Eupatoriophalacron *Americanum procumbens, origani folio, flore luteo. Houſt.* Trailing *American* Naked-headed Hemp-agrimony, with an origany Leaf, and a yellow Flower.

All theſe Plants are annual, ſo muſt be ſown every Spring on a Hot-bed, and muſt be tranſplanted afterward to another, in order to bring them forward, otherwiſe they will not perfect their Seeds in this Country; for moſt of them are Natives of the warmer Parts of *America*, therefore they muſt be treated after the Manner of *Amaranths*, bringing them forward on Hot-beds until *June*; about the Middle of which Month, they may be tranſplanted into Beds or Borders of rich Earth; where, if they are duly watered in dry Weather, they will produce their Flowers in *July*, and their Seeds will ripen in *September*. There is no great Beauty in theſe Plants, ſo they are ſeldom cultivated but in Botanick Gardens for the ſake of Variety.

EUPATORIUM, [Εὐπατόριον, of King *Eupato*, who firſt brought this Plant into Uſe; or of ἡπατίτης, of ἧπαρ Gr. the *Liver*, becauſe this Plant is good for Diſeaſes of the Liver; or of εὐπατὴρ, i. e. *good Father*, or, *a Son beloved by his Father*, which Name many of the Kings of *Egypt* have borne] Hemp-Agrimony.

The *Characters* are;

It hath a perennial fibroſe Root; the Leaves are placed oppoſite upon the Stalks; the Cup of the Flower is long, taper, and ſcaly; the Flowers are collected into an Umbel upon the Tops of the Stalks, which conſiſt of many long bifid Threads.

The *Species* are;

1. EUPATORIUM *Cannabinum. C. B.* Common Hemp-Agrimony.
2. EUPATORIUM *urticæ foliis, Canadenſe, flore albo. H. L.* Canada Hemp-Agrimony, with Nettle Leaves, and a white Flower.
3. EUPATORIUM *Novæ Angliæ, urticæ foliis, floribus purpuraſcentibus, maculato caule. H. L. New England* Hemp-Agrimony, with Nettle Leaves, purpliſh Flowers, and ſpotted Stalks.
4. EUPATORIUM *folio oblongo rugoſo, caule purpuraſcente. Tourn.* Canada Hemp-Agrimony, with a long rough Leaf, and purpliſh Stalk.
5. EUPATORIUM *Novæ Angliæ, Betonicæ foliis villoſis, flore albo. Par. Bat. New England* Hemp-Agrimony, with Betony Leaves, and a white Flower.
6. EUPATORIUM *Americanum, ſcandens, haſtato magis acuminato folio. Vaill.* Climbing American Hemp-Agrimony, with a Spear-like ſharp-pointed Leaf.
7. EUPATORIUM *Americanum, foliis rotundioribus abſque pediculis. Vaill.* American Hemp-Agrimony, with round Leaves without Foot-ſtalks.
8. EUPATORIUM *ſcandens, foliis ſubrotundis lucidis, floribus ſpicatis albis. Houſt.* Climbing Hemp-Agrimony, with roundiſh ſhining Leaves, and white Flowers growing in a Spike.
9. EUPATORIUM *Americanum, teucrii folio, flore niveo. Vaill. Mem. Acad. Scien. American* Hemp-Agrimony, with a tree-germander Leaf, and a white Flower.
10. EUPATORIUM *Virginianum, ſalviæ foliis longiſſimis acuminatis, perfoliatum. Pluk. Almag. Virginian* Hemp-Agrimony, with long ſage-like Leaves cloſely ſurrounding the Stalk.
11. EUPATORIUM *betonicæ folio glabro & carnoſo, flore cœruleo. Houſt.* Hemp-Agrimony, with a fleſhy ſmooth betony Leaf, and a blue Flower.
12. EUPATORIUM *Americanum arboreſcens, mori folio, floribus albicantibus. Houſt.* Tree-like *American* Hemp-Agrimony, with a Mulberry-leaf, and white Flowers.
13. EUPATORIUM *Americanum fruteſcens, balſaminæ luteæ foliis, nigris maculis punctatis. Houſt. American* ſhrubby Hemp-Agrimony, with yellow Balſamine Leaves ſpotted with black Marks.
14. EUPATORIUM *Peruvianum, folio ſubrotundo trinervi utrinque acuto, flore cœruleo. Vaill. Mem. Acad. Scien. Peruvian* Hemp-Agrimony, with roundiſh Leaves ending in a ſharp Point, and blue Flowers.

The firſt of theſe Plants is found wild by Ditches and River Sides in moſt Parts of *England*, and is the only Species of this Genus which is a Native in *Europe*: but *America* abounds with a vaſt Number of Species, many of which are annually brought over, and preſerved in curious Botanick Gardens; tho' the firſt Sort is only at preſent uſed in Medicine.

Theſe Plants are moſt of them hardy enough to endure the Cold of our Winters in the open Air, provided they are planted in a dry Soil, and may be propagated by parting their Roots in *March*, or *October*: but if you do this in the Spring, you muſt obſerve to water and ſhade the Plants until they have taken Root, if the Weather ſhould prove dry; and thoſe that are tranſplanted in Autumn, ſhould be protected from ſevere Froſts in Winter, which would be apt to deſtroy them before they have got faſt Rooting in the Ground.

Theſe Plants may alſo be propagated by ſowing their Seeds, which ſhould be done early in the Spring, upon a Bed of light Earth, obſerving to water them in dry Weather: but they ſeldom come up until the ſecond Year; and it is not till the third Year that they produce Flowers: therefore, if the Plants are not too thick in the Seed-bed, they may be permitted to remain there till after their Flowers are paſt; and in *October* remove them to the Places where they are deſign'd to grow. Theſe Plants have little Beauty in them, and therefore are ſeldom preſerved, unleſs in Botanick Gardens, for Variety.

The eighth, eleventh, twelfth, thirteenth and fourteenth Sorts, are ſomewhat tenderer than the others before-mentioned, and require to be ſheltered in Winter: the eighth Sort dies to the Root every Autumn, and riſes again the following Spring. This may be propagated by parting of the Roots in *April*, juſt before they begin to ſhoot; this Plant muſt be frequently watered in dry Weather, during the Seaſon of its Growth; but in Winter, when the Stems are decayed, it ſhould have but little Water; for too much Wet at that Seaſon will rot the Roots.

The ninth, twelfth, thirteenth and fourteenth Sorts, may be propagated by Cuttings during the ſummer Seaſon; which ſhould be planted into Pots, filled with freſh light Earth, and plunged into a moderate Hot-bed, where they ſhould be ſhaded and watered until they have taken Root, when they may be expoſed to the open Air by degrees. Theſe Plants may be placed in the open Air in Summer, among other hardy exotic Plants; but in Winter they ſhould be placed in a good Greenhouſe, obſerving to let them have the free Air in mild Weather; and they muſt be frequently refreſhed with Water. With this Management theſe Plants will flower every Year, and may be allowed a Place in ſuch Gardens where other exotic Plants are preſerved.

EUPHORBIUM, [Εὐφόρβιον, ſo named by King *Juba*, from *Euphorbus*, the Brother of *Antonius Muſa*, who was his Phyſician.]

The *Characters* are;

It hath Flowers and Fruit like the Spurge, *and is alſo full of a hot, ſharp, milky Juice; the Plants are angular, and ſhaped ſomewhat like the* Cereus *or* Torch Thiſtle; *it is commonly beſet with Spines, and, for the moſt part, hath no Leaves.*

The *Species* are;

1. EUPHORBIUM *verum antiquorum. Raii Hiſt.* The true *Euphorbium* of the Ancients.
2. EUPHORBIUM *tetragonum & pentagonum, ſpinoſum, Canarinum. Boerh. Ind.* Canary *Euphorbium*, with four or five Angles, and beſet with Spines.
3. EUPHORBIUM *trigonum & tetragonum, ſpinoſum, ramis compreſſis. D'Iſnard.*
4. EUPHORBIUM *Cerei effigie, caulibus craſſioribus, ſpinis validioribus armatum. Breyn. Prod.* Thick-ſtalk'd *Cereus*, like *Euphorbium*, arm'd with ſtrong Spines.
5. EUPHORBIUM *Cerei effigie, caulibus gracilioribus. Boerh. Ind.* Slender-ſtalk'd *Cereus*, ſhaped like *Euphorbium*.
6. EUPHORBIUM *Afrum, caule ſquamoſo tuberoſo. Boerh. Ind.* African *Euphorbium*, with ſcaly Stalks and a tuberoſe Root.
7. EUPHORBIUM *Afrum, caule ſquamoſo tuberoſo, minus. Boerh. Ind.* Leſſer African *Euphorbium*, with ſcaly Stalks, and a tuberoſe Root.
8. EUPHORBIUM *Afrum, caule craſſo ſquamoſo, ramis in capitis Meduſæ ſpeciem cincto. Boerh. Ind.* African *Euphorbium*, with thick ſcaly Stalks, and branching at the Top like *Meduſa*'s Head, *commonly call'd* the Snake-*Euphorbium*.
9. EUPHORBIUM *Afrum, facie fructus pini. Boerh. Ind.* African *Euphorbium*, with the Face of the Pine-Fruit, *commonly call'd* Little *Meduſa*'s Head.
10. EUPHORBIUM *anguloſum, foliis nerii latioribus. Boerh. Ind.* Angular *Euphorbium*, with broad Oleander Leaves.
11. EUPHORBIUM *heptagonum, ſpinis longiſſimis, in apice frugiferis. Boerh. Ind.* *Euphorbium* with ſeven Angles, and long Spines bearing Fruit upon the Tops.
12. EUPHORBIUM *quod Anteuphorbium. Dod.* The *Anti-Euphorbium: Vulgo.*

All theſe Plants being Natives of warm Countries, muſt with great Care be preſerved in Stoves during the Winter; and being replete with a milky Juice, they require very little Moiſture: nor ſhould they be planted in a rich Soil, which is very hurtful to them. They are all (ſo far as we are acquainted with their Places of Growth) Inhabitants of rocky hard barren ſoils: therefore the moſt proper Earth for them, is one half Sea-ſand, one quarter light freſh Earth, and a quarter part Lime-Rubbiſh: this ſhould be mix'd up well together two or three Months before it is uſed, obſerving to turn it over three or four times, that the ſeveral Parts may be the better united; and afterwards, it will be proper to ſcreen it, in order to take out the large Stones.

Theſe Plants are propagated by planting Cuttings: the beſt Seaſon for this is in *June* or *July*: the Cuttings ſhould be taken off from the old Plants at a Joint; for if they are cut in the Middle of the Joint, the Cutting will decay, as will alſo that Part of the Branch left on the old Plant to the next Joint, and ſometimes it will mortify and decay the whole Plant. Theſe ſhould be cut off a Week or Fortnight before they are planted; during which Time, they ſhould lie in a dry ſhady Place, that the Part which adhered to the old Plant may be dried and harden'd, otherwiſe the Cuttings will rot: then plant them into ſmall Half-penny Pots fill'd with the above-mention'd Earth, giving them a little Water to ſettle the Earth to them, and let the Pots be ſet for a Day or two in a Place where they may have only the Morning Sun: after this, plunge them into a moderate Hot-bed of Tanners Bark, obſerving, in the great Heat of the Day, to ſhade the Glaſſes with Mats, as alſo, once a Week, to give them a gentle Refreſhing with Water: but you muſt be very careful not to give them too much, which will immediately rot them, eſpecially before they have taken Root.

In about five or ſix Weeks time the Cuttings will have ſhot out ſome Roots, which you may eaſily perceive, by carefully obſerving the Tops of the Cuttings, which will then begin to advance in Height, and appear of a lighter Green Colour than the lower Part; at which time you muſt begin to give them Air by degrees, raiſing the Glaſſes with Bricks in the Middle of the Day, and ſo increaſing the Quantity of Air daily, until at laſt you remove them quite out of the Bark-bed, which ſhould be done towards the latter End of *Auguſt*, when you ſhould place them into the Stove, obſerving not to expoſe them too much to the Air; alſo being very careful not to let them have too much Moiſture, which is very deſtructive to theſe Plants.

During the Winter Seaſon they muſt be placed in a warm Part of the Stove, which ſhould always be kept to the Temperate Heat, as mark'd on Mr. *Fowler's Botanical Thermometers*, which I find does better agree with all the Sorts of this Plant, than a greater Degree of Heat. The firſt, third, and eleventh Sorts are the tendereſt, and ſhould therefore be placed nearer to the Fire-place in the Stove than the other Sorts, eſpecially the eleventh, which ſhould be placed to receive as much Light as poſſible, and muſt not have one Drop of Water from *October* till *March*; for it is very ſubject to rot, upon receiving the leaſt Moiſture at that Seaſon; but the other Sorts will require a little Water every Fortnight or three Weeks, eſpecially if they ſtand in a Stove where the Heat is regularly kept up; this will preſerve the Plants from ſhrinking, which they are ſometimes ſubject to, when they are kept too dry.

Theſe Plants ſhould not be expoſed to the open Air in Summer, but always allowed to continue in the Stove, obſerving to place them as near the Windows as conveniently you can, that they may enjoy as much free Air as poſſible: When the Weather will permit, the Glaſſes ſhould be open'd; but they ſhould never be expoſed in the Night, or to hard Rains.

July is the beſt Seaſon for ſhifting theſe Plants, when you ſhould be provided with a Quantity of the before-mention'd Earth, and after having ſhaken them out of the Pots they before grew in, you ſhould with your Hands take off as much of the Earth round the Roots of the Plants as poſſible, without breaking them; then having put a few Stones in the Bottom of the Pots, to drain off the Moiſture, you ſhould fill the Pots about half full of the new Earth, and ſet the Plants in the Middle of the Pots, filling up the Vacancies with the Earth, and preſſing it down gently with your Hands, to ſettle the Earth cloſe to the Roots of the Plants: Afterwards give them a little Water, and then remove them into the Stove again; obſerving, if the Weather ſhould be very hot and dry, to ſcreen the Glaſſes of the Stove in the Middle of the Day, until the Plants are well rooted again.

N. B. You muſt never put thoſe Plants into large Pots; for as they are moſt of them Inhabitants of Rocky Places, ſo they ſhould be pretty much confined in their Roots; for if the Pots are too big, the Plants, if they don't rot, will make but ſmall Progreſs therein.

The firſt of theſe Sorts is by many learned Authors ſuppoſed to be the true *Euphorbium* of the Antients; tho' I believe, what we now uſe, is taken from more Species of this Plant than one. And I am credibly inform'd by a very curious Gentleman, who lived many Years in the *Canaries*, That the greateſt Part of the *Euphorbium* uſed in *England* came from thence, and is produced from the ſecond Sort. And by carefully looking over ſome of this Drug in a Shop, I found ſeveral Spines amongſt it, which exactly agreed with thoſe of that Plant.

The twelfth Sort is by ſome ſuppoſed to be an Antidote to the *Euphorbium*; but with how much Juſtice, I can't ſay: However, as it has been by moſt Authors ranged amongſt thoſe Plants, I thought proper to continue it there; tho' indeed it has little Affinity with them in its outward Appearance, nor is its Juice milky or hot: But as it hath not as yet produced any Flowers in *Europe*, ſo we can't tell how to diſpoſe it under a particular Genus, which may be more fit for it than this to which it is at preſent fix'd.

This Plant requires a leſs Degree of Heat in Winter, and to be oftener water'd than any of the other Kinds, and is much eaſier increaſed, whereby it is more common than the others, and is leſs eſteem'd, as being very difficult to reduce to any regular Figure.

The eleventh Sort is one of the moſt beautiful, and by far the moſt rare of any of the Species, and is only to be found at preſent in two or three very curious Gardens in *England*. This is very difficult to preſerve, as alſo to increaſe; for the Cuttings, if they are not well dried before they are planted, will certainly rot.

The firſt is alſo a very beautiful Plant, and is pretty rare: but as it is eaſily propagated, ſo it will ſoon become more common in *England*; as will alſo the third Sort, which is at preſent leſs common than many of the others.

But the ſecond is a Plant of a wonderful Structure; the Branches coming out from every Side of the main Stem, and turning upwards, do very much reſemble the branch'd Candleſticks in Churches: This is pretty common in *England*, and has been an old Inhabitant of the *Engliſh* Gardens.

EUPHRASIA, Eye-bright.

The *Characters* are;

It hath an anomalous perſonated Flower of one Leaf, divided into two Lips; the upper one upright and parted into ſeveral Diviſions, and the lower one is divided into three Parts, each of which is again divided into two: out of the Flower-cup riſes the Pointal, which afterwards turns to a Fruit or oblong Huſk, divided into two Parts, and replete with ſmall Seeds.

The *Species* are;

1. EUPHRASIA *officinarum. C. B. P.* Common Eye-bright.
2. EUPHRASIA *ramoſa pratenſis, flore albo. Hort. Eyſt.* Branched Meadow Eye-bright, with a white Flower.
3. EUPHRASIA *minus ramoſa, flore ex cœruleo-purpuraſcente. Hort. Eyſt.* Eye-bright leſs branched, with a purple blue Flower.
4. EUPHRASIA *Alpina parva, luteis floribus. C. B. P.* Small Mountain Eye-bright with yellow Flowers.

The firſt Sort is very common in the Meadows in moſt Part of *England*, where the Herb-women gather it to ſupply the Markets, it being very much uſed for Diſorders of the Eyes. The other Sorts are not common in *England*, nor are they ever gathered for Uſe: they are all of them annual Plants, which drop their Seeds in the Places of their Growth, and riſe again without any Culture. Theſe Plants are difficult to keep in Gardens, for unleſs their Seeds are permitted to fall when ripe, and the Plants ſuffered to come up in the ſame Places, they ſeldom ſucceed; nor do their Seeds ſcarce ever grow, if they are kept out of the Ground till Spring; ſo that they muſt be ſown ſoon after they are ripe. But as the only Sort which is uſed in Medicine grows plentifully in the Fields in this Country, ſo it is not cultivated in Gardens. The beſt Time to gather this Herb for Uſe, is in *June*, when it is in Flower.

EXCORTICATION, [*Excorticatio*, Lat.] a Pulling or Peeling off the outward Bark of Trees.

EXOTICKS, [*Exotica*, Lat.] *Exotick Plants*, are ſuch as are Natives of Foreign Countries.

F A

FABA, [of φαγεῖν, Gr. *to eat*; becauſe the Seed of it is very much eaten] The Bean.

The *Characters* are;

It hath a papilionaceous Flower, which is ſucceeded by a long Pod, which is fill'd with large flat Kidney-ſhaped Seeds: The Stalks are firm, and hollow; the Leaves grow by Pairs, and are faſten'd to a Mid-rib.

The *Species* are;

1. FABA *major recentiorum. Lob. Icon.* The common Garden-Bean.
2. FABA *minor, ſeu Equina. C. B.* The Horſe-Bean.

There are ſeveral Varieties of theſe two Sorts of *Beans*, which differ either in Colour or Size; but as theſe are only ſeminal Variations, ſo I think it needleſs to mention them here, ſince every one who has cultivated them, knows that they every Year vary in their Colour and Size. The particular Direction for their Culture, you will ſee under the Article of *Bean*.

FABA ÆGYPTIA. *Vide* Arum Ægyptiacum.

FABA CRASSA. *Vide* Anacampſeros.

FABAGO, Bean-Caper, [is ſo call'd of *Fabis*, Lat. *Beans*, becauſe its Leaves reſemble thoſe of Beans; and *Capers*, of *Capparis*] the Fruit of this Plant being like that of the Caper.

The *Characters* are;

The Leaves are produced by Pairs upon the ſame Foot-ſtalk, which Foot-ſtalks grow oppoſite at the Joints of the Stalks: the Cup of the Flower conſiſts of five Leaves: The Flowers alſo conſiſt of five Leaves, which expand in Form of a Roſe, and have many Stamina or Threads that ſurround the Style in the Center of the Cup; which Style becomes a cylindrical Fruit, and is, for the moſt part, five-corner'd, divided into five Cells by intermediate Partitions, each of which contains many flat Seeds.

The *Species* are;

1. FABAGO *Belgarum, ſive Peplus Pariſienſium. Lugd.* Bean-Caper, *vulgo*.
2. FABAGO *Africana, arboreſcens, flore ſulphureo, fructu rotundo. Com. Rar. African* Tree Bean-Caper, with a Sulphur-colour'd Flower, and a round Fruit.
3. FABAGO *Africana, fruteſcens, folio latiori, fructu tetragono. African* ſhrubby Bean-Caper, with broader Leaves, and a four-corner'd Fruit.

The firſt of theſe Plants is pretty hardy, and will endure the Cold of our Winters in the open Air, provided it be planted in a dry Soil, and a warm Situation: This is propagated by ſowing the Seeds in the Spring, either on a warm Border or a moderate Hot-bed; and when the Plants are come up, they may be planted into Pots fill'd with light ſandy Earth, or in warm Borders under Walls or Hedges of the like Soil; for they do not care for a rich dung'd Soil, nor a ſtrong or moiſt Earth. The Diſtance theſe Plants ſhould be planted at, muſt not be leſs than two Feet each Way; for they grow to be very large, and form a ſtrong Head: The Branches die away every Winter to the Head, and ſhoot again the ſucceeding Spring, and will produce great Plenty of Flowers and Roots annually, and their Roots will abide many Years, but are very apt to die if removed after they are grown large.

This Plant is of no Uſe at preſent in *England*, but for the Variety of its Flowers deſerves a Place in good Gardens.

The other two Sorts, being Natives of a warm Country, will not endure the Cold of our Climate abroad, but muſt be preſerved in a Green-houſe: They may be propagated by ſowing their Seeds upon a Hot-bed in the Spring; and when the Plants come up, they ſhould be planted into Pots fill'd with freſh ſandy Earth, and may be expoſed during the Summer with other Green-houſe Plants, but in Winter ſhould be placed in an airy Part of the Houſe, and muſt not be crowded with other Plants, which will cauſe them to mould, and ſhed their Leaves, and many Times deſtroy the whole Plant: They ſhould alſo have frequent Refreſhings with Water, but ſhould not have too much at a Time, for that very often deſtroys theſe Plants.

They may alſo be increaſed by planting Cuttings in any of the Summer Months into Pots of light Earth, which ſhould be plunged into a moderate Hot-bed, to facilitate their Rooting, obſerving to ſhade them from the Violence of the Sun, as alſo to give them Water frequently: When they are rooted, which will be in about two Months after planting, they may be tranſplanted into ſeparate Pots fill'd with the ſame light Earth, and ſhould be expoſed to the open Air by degrees, and afterwards may be treated as was before directed for thoſe rais'd from Seeds.

Theſe Plants are generally preſerv'd in all curious Collections of Plants for Variety, but are of no Uſe with us at preſent.

FAGONIA. *This Plant was ſo named by Dr.* Tournefort, *in Honour to Dr.* Fagon, *who was Superintendant of the Royal Garden at* Paris.

The *Characters* are;

The Flower conſiſts of many Leaves, which are placed orbicularly, and expand in Form of a Roſe; out of whoſe Center riſes the Pointal, which afterward becomes a channelled round pointed Fruit, conſiſting of many Cells, and compoſed of many Huſks, each containing one roundiſh Seed.

The *Species* are;

1. FAGONIA *Cretica ſpinoſa. Tourn.* Thorny Trefoil of *Candy*.
2. FAGONIA *Hiſpanica non ſpinoſa. Tourn. Spaniſh* Fagonia without Thorns.

The firſt of theſe Plants is peculiar to *Crete*, from whence it hath been brought by ſome curious Botaniſts, and is preſerved in botanic Gardens. The other Sort was diſcovered by Dr. *Tournefort*, in *Spain*, who ſent the Seeds to the Royal Garden at *Paris*; from whence it hath been diſtributed to ſeveral curious botanic Gardens.

Theſe Plants may be propagated by Seeds, which ſhould be ſown in *March*, on a Border of light Earth, covering them about a Quarter of an Inch with Earth; in *April* the Plants will appear above Ground, when they ſhould be carefully weeded, and in dry Weather they muſt be frequently watered, which will greatly promote their Growth; toward the latter End of *May* the Plants will be ſtrong enough to tranſplant, at which Time they ſhould be carefully taken up, and planted about ſix Inches aſunder, in a Bed or Border of freſh light Earth, obſerving to ſhade them from the Sun until they have taken Root; after which Time they muſt be kept clear from Weeds, and in dry Weather they ſhould be refreſhed with Water. In this Place the Plants may remain till *Michaelmas*, when they ſhould be taken up with Balls of Earth to their Roots, and tranſplanted into the Borders where they are deſigned to remain; and the following Summer they will produce their Flowers, when they will add to the Variety amongſt other hardy Plants.

FAGOPYRUM; [of Φάγω, *to eat*, and πυρὸς, *Bread-corn*, becauſe an edible Grain; or of *Fagus*, the *Beech-tree*, becauſe it has triangular Seeds like thoſe of the *Beech*] Buck-Wheat.

The *Characters* are;

The Flowers are ſpecious, growing in a Spike, or branch'd from the Wings of the Leaves; the Cup of the Flower is divided into five Parts, which reſemble the Petals of a Flower; the Seeds are black, and three-corner'd.

The *Species* are;

1. FAGOPYRUM *vulgare erectum. Tourn.* Common upright Buck-Wheat.
2. FAGOPYRUM *vulgare ſcandens. Tourn.* Common creeping Buck-Wheat.

The firſt of theſe Plants is cultivated in many Parts of *England*, and is a great Improvement to dry barren Lands. The beſt Seaſon for ſowing the Seed is in *May*: One Buſhel will ſow an Acre. The Ground ſhould be plough'd and dreſs'd in the ſame Manner as for *Barley*; and if the Soil is not very lean, it will yield a very great Increaſe, as fifty or ſixty Buſhels upon an Acre, and is excellent Food for Hogs, Poultry, *&c.* The Flour of it is very white, and makes a very good Sort of Pancake, if mix'd with a little Wheat-flour. The Straw is good Fodder for Cattle; and the Grain given to Horſes amongſt their Oats, will make them thrive; but it muſt be broken in a Mill, otherwiſe it is apt to paſs thro' the Cattle whole.

It is commonly late in the Seaſon before it is ripe, but there is no great Danger of the Seeds falling, nor of ſuffering by Wet after it is mown: It muſt lie ſeveral Days to dry, that the Stalks (which are hard) may wither before it is hous'd.

Buck-Wheat is ſometimes ſown very thick, and ſuffer'd to grow until it is near flowering, and is then plough'd in, which makes a very good Lay for *Wheat* or *Rye*: But ſome People eſteem it the better Way to feed Cattle with it, eſpecially Milch-Cows, which they ſay, will cauſe them to give a great deal of Milk, and make both the Butter and Cheeſe very good. This will alſo afford Food for Cattle in the drieſt Time, when all other Graſs is burnt up.

The ſecond Sort is found wild in divers Parts of *England*, but is ſeldom cultivated for Uſe.

FAGUS; [is ſo call'd of φάγω, Gr. *to eat*, becauſe its triangular Nuts are edible, and afford good Nutriment: It is call'd in *Greek* ὀξύα, of ὀξύνη, of ὀξὺς, Gr. *ſharp*, becauſe its Fruit is acuminated] The Beech-Tree.

The *Characters* are;

It hath Leaves ſomewhat reſembling thoſe of the Horn-bean; *the Male Flowers grow together in a round Bunch, and are produc'd at remote Diſtances from the Fruit on the ſame Tree; the Fruit conſiſts of two triangular Nuts, which are incloſ'd in a rough hairy Rind, divided into four Parts.*

The *Species* are;

1. FAGUS. *Dod.* The Beech-Tree.
2. FAGUS *foliis ex luteo variegatis.* The yellow-ſtrip'd Beech-Tree.
3. FAGUS *foliis ex albo variegatis.* The white-ſtrip'd Beech-Tree.

There is but one Specie of this Tree at preſent known, (except the two Varieties with ſtriped Leaves, which are accidental) tho' the Planters would diſtinguiſh two or three Sorts; one of which they call the *Mountain-Beech*, and, as they ſay, affords a much whiter Timber than the other which they call the *Wild Beech*: But as theſe have never been diſtinguiſh'd by the *Botaniſts*, nor can I perceive any real Difference amongſt all the Trees of this Kind I have yet ſeen, ſo I rather think the Difference in the Colour of the Wood is occaſion'd by the Places of their Growth; which is often obſerv'd to be the Caſe with moſt other Sorts of Timber.

This Tree is propagated by ſowing the Maſt; the Seaſon for which is any Time from *October* to *February*, only obſerving to ſecure the Seeds from Vermin when early ſow'd; which if carefully done, the ſooner they are ſown the better, after they are fully ripe: A ſmall Spot of Ground will be ſufficient for raiſing a great Number of theſe Trees from Seed, but you muſt be very careful to keep them clear from Weeds; and if the Plants come up very thick, you ſhould not fail to draw out the ſtrongeſt of them the Autumn following, that thoſe left may have Room to grow: So that if you huſband a Seed-bed carefully, it will afford a three Years Draught of young Plants; which ſhould be planted in a Nurſery, and if deſign'd for Timber-trees, at three Feet Diſtance Row from Row, and eighteen Inches aſunder in the Rows.

But if they are deſign'd for Hedges, (to which the Tree is very well adapted) the Diſtance need not be ſo great; two Feet Row from Row, and one Foot in the Rows will be ſufficient. In this Nurſery they may remain two or three Years, obſerving to clear them from Weeds, as alſo to dig up the Ground between the Roots, at leaſt once a Year, that their tender Roots may the better extend themſelves each Way; but be careful not to cut or bruiſe their Roots, which is injurious to all young Trees, and never dig the Ground in Summer, when the Earth is hot and dry, which by letting in the Rays of the Sun to the Roots, is often the Deſtruction of young Trees.

This Tree will grow to a conſiderable Stature, tho' the Soil be ſtony and barren, as alſo upon the Declivities of Hills, and chalky Mountains, where they will reſiſt the Winds better than moſt other Trees; but then the Nurſeries for the young Plants ought to be upon the ſame Soil; for if they are raiſed in a good Soil and a warm Expoſure, and afterwards tranſplanted into a bleak, barren Situation, they ſeldom thrive; which holds true in moſt other Trees: Therefore I would adviſe the Nurſery to be made upon the ſame Soil where the Plantation is intended: But of this I ſhall ſay more under the Article of *Nurſery*.

The Tree is very proper to form large Hedges to ſurround Plantations or large Wilderneſs Quarters, and may be kept in a regular Figure, if ſhear'd twice a Year, eſpecially if they ſhoot ſtrong; in which Caſe, if they are neglected but a Seaſon or two, it will be difficult to reduce them again. The Shade of this Tree is very injurious to moſt Sorts of Plants which grow near it, but is generally believed to be very ſalubrious to human Bodies.

The Timber is of great Uſe to Turners for making *Trenchers*, *Diſhes*, *Trays*, *Buckets*; and likewiſe to the Joyner for *Stools*, *Bedſteads*, *Coffers*, &c. The Maſt is very good to fat *Swine* and *Deer*; it alſo affords a ſweet *Oil*, and hath in ſome Families ſupported Men with Bread.

The two Sorts with variegated Leaves, may be propagated by budding or grafting them upon the common Beech, obſerving not to plant them in a good Earth, which will cauſe the Buds or Cyons to ſhoot vigorouſly, whereby the Leaves will become plain, which often happens to moſt variegated Plants.

FARINA FOECUNDANS, is the impregnating Meal or Duſt on the *Apices* of Flowers, which being convey'd into the *Uterus* or *Vaſculum Seminale* of Plants, fecundates the Rudiments of the Seeds in the *Ovary*, which otherwiſe would decay and come to nothing. See *Generation of Plants*.

FEATHERFEW or FEAVERFEW. *Vide* Matricaria.

FEBRUARY.

Work to be done in the KITCHEN-GARDEN.

If the Weather be mild in this Month, there is a great deal of Buſineſs to be done in the Kitchen Garden, which, if omitted, will be of bad Conſequence, moſt of the principal Crops being now to be ſown or planted; which if done later in the Year, do ſeldom ſucceed ſo well, eſpecially upon dry Land.

You muſt now dig and prepare your Ground for Carrots, Parſnips, Onions, Leeks, Radiſhes, Spinach, and Cabbage-Lettuce, which ſhould now be ſown; but where it is only for the Supply of a Family, there ſhould not be too much of each Sort ſown at once; For it is a much better Way to ſow three or four Times of each Sort at about ten Days Diſtance from each other, that there may be a Continuation of them for the Kitchen, than to truſt to one Sowing, which will laſt but a ſhort Time: Beſides, if the firſt or ſecond Sowing ſhould miſcarry, it is probable the other may do well, and then there will be no Diſappointment of a Crop.

This is alſo the Seaſon for ſowing Scorzonera, Salſafy, Beets, Skirrets, Parſley, Corn-Sallet, with moſt other hardy Plants; theſe are beſt ſown in ſeparate Beds, and afterwards thinn'd to the proper Diſtance which each requires; for where they are ſown with other Crops, they do not thrive ſo well; nor ſhould they be left too cloſe, for then the Plants will draw each other up weak, and become ſmall.

Make moderate Hot-beds for ſowing ſome Cauliflower-feed, for Summer-plants to ſupply the Kitchen, after thoſe which were ſown in *Auguſt* are gone; but theſe are only fit for a moiſt Soil; for in a dry Ground they ſeldom produce large Heads.

Plant Garlick, Shallots, Rocambole and Cives; as alſo Onions, to draw up for Scallions in *April*, when the dry Onions will be gone, and the *Michaelmas* Onions will be too ſmall for many Kitchen Uſes.

If the laſt Month was ſo ſevere that little Work could be done in the Garden, then there will be a Neceſſity for forwarding Buſineſs in this, provided the Seaſon is favourable; therefore now ſhould be planted out ſome of the Sugar-loaf and Long-ſided Cabbages, to ſucceed thoſe which were planted in *November*. You muſt alſo tanſplant your Cauliflower-plants out of the Winter-beds to the Places where they are to grow, and towards the End of the Month you muſt ſlip your old Artichoke-ſtocks, and plant out ſome of the cleareſt and moſt promiſing Plants for a new Plantation; theſe will produce Fruit in Autumn, after thoſe on the old Stocks are gone. The particular Directions for doing this are exhibited under their proper Heads.

Continue to plant Beans, and ſow Peaſe every Fortnight, that there may be no want of theſe Things in the Kitchen during the Seaſon: But now it is proper to plant only the *Windſor*-Bean; and ſome of the larger Sorts of Peaſe ſhould now be ſown, particularly the *Spaniſh* Morotto, which is a plentiful bearing Sort, and a very good Pea for eating.

Make new Hot-beds for Aſparagus to ſucceed thoſe which were made the laſt Month, for otherwiſe there will be a want in the Kitchen, one of theſe Beds ſeldom continuing much more than a Fortnight in good Order; ſo that in this Month there ſhould be two Beds made, at about ſixteen or eighteen Days Diſtance, that they may ſucceed each other regularly.

The Cucumber and Melon-plants which were rais'd the laſt Month, will now be fit to tranſplant; therefore there muſt be new Beds made for them, which ſhould be well wrought; but the Plants muſt not be planted therein, until the violent Heat of the Bed is over, which ſeldom laſts above a Week, eſpecially if the Dung had been well prepar'd before it was uſ'd. At this Seaſon you muſt attend very cloſely to your Hot-beds, if you would have them ſucceed; for a ſmall Neglect at this Seaſon will deſtroy all your Plants, and put you greatly backward.

Plant ſome Kidney-Beans upon a moderate Hot-bed for an early Crop, obſerving, when the Plants are come up, to give them Air whenever the Weather will permit, othewiſe the Plants will draw up weak, and not produce Fruit. The beſt Sort for this Purpoſe is the Dwarf *Batterſea*-Bean, which ſeldom runs much to haulm, and is a plentiful Bearer.

If the Weather be favourable, toward the End of this Month you muſt plant your *Cos*, *Sileſia* and *Imperial* Lettuces, from the Beds or Borders where they grew in the Winter; but ſome of the Plants ſhould be left to remain for Cabbaging, becauſe they will come earlier than thoſe which are remov'd. You ſhould alſo ſow ſome Seeds of theſe Sorts upon a Spot of good Ground, to come after the Winter Lettuces are gone.

The latter End of the Month you may ſow ſome Cabbages and Savoys for Winter uſe; and upon Hot-beds or warm Borders muſt be ſown ſome ſmall Sallet-herbs, as Lettuce, Creſſes, Muſtard, Rape, Radiſh, Turnips, *&c.* that there may be a conſtant Supply of theſe Things for the Table.

Sow ſome Celery Seeds upon a Bed of rich Earth, in a warm Situation, to come up early; and you ſhould now ſow Aſparagus Seed in a Bed of good Earth, for Plants againſt the next Year, to make freſh Plantations.

Tranſplant Cabbages, Savoys, Leeks, Parſnips, Carrots, and Beets for Seed, if it was not done the former Month, obſerving (as was there directed) to hang up the Cabbages and Savoys in a dry Place for five or ſix Days, that the Wet may drain out from between the Leaves, which, if left in, would rot them.

Plant Potatoes and Jeruſalem-Artichokes, obſerving to plough or trench the Ground deep, that the Roots may be plac'd at leaſt ſix or eight Inches below the Surface, otherwiſe they will not ſucceed ſo well.

Dung and trench the Ground well, where you intend to plant Aſparagus, letting it remain in Ridges until the Seaſon for planting, which will be the latter End of next Month.

The Cauliflower-plants which were plac'd under Bell or Hand-Glaſſes in *October* laſt, ſhould, toward the End of this Month, be parted, leaving only one of the ſtrongeſt Plants under each Glaſs; but in doing of this you muſt be careful not to diſturb the Roots of thoſe Plants which are left; and if they are grown ſo large as to preſs againſt the Glaſſes, you ſhould raiſe the Earth in a Border about the Plants, that the Glaſſes may be advanc'd ſo as not to cruſh the Plants.

The Peaſe and Beans which were ſown in Autumn, and have ſtood thro' the Winter, will now begin to advance; therefore the Ground between them ſhould be houghed, and the Earth drawn up to their Stems, which will ſtrengthen them, and guard their Stems from the Injury of Froſt.

Products of the KITCHEN-GARDEN.

Cabbages, Savoys, Borecole, Broccoli, Carrots, Parſnips, Turnips, Beets, Skirrets, Scorzonera, Salſafy, Coleworts, Spinach, Potatoes, Jeruſalem-Artichokes; and in ſome warm Borders there are Radiſhes which were ſown in Autumn. Upon Hot-beds all Sorts of ſmall Sallet-herbs, as Lettuce, Creſſes, Coriander, Turnip, Rape, Radiſh and Muſtard. You have alſo Endive and Celery; and on the Hot-beds made in *December*, you have Aſparagus, which towards the middle of this Month, when there begins to be ſome ſunny Weather to colour it, will be very good.

Work to be done in the FRUIT GARDEN.

You may now continue to prune ſuch of your Fruit-trees as were not before prun'd, either againſt Walls, Eſpaliers, or Standards, obſerving to do the more hardy Sorts firſt, and let the tender Kinds alone till laſt, when there will be leſs Danger of their ſuffering by cold.

The Fig-trees, which were cover'd in froſty Weather to protect their tender Branches from Injury, ſhould be open'd in warm Weather to admit freſh Air, otherwiſe they will be in Danger of growing mouldy, which would decay them.

Where-ever your Eſpaliers are decay'd, and have not been repair'd the former Months, it ſhould be no longer deferr'd, becauſe the Buds of the Fruit-trees will now begin to ſwell, and thereby be in Danger of rubbing off, and ſuch of your Trees as have not been train'd to the Eſpaliers already, muſt now be prun'd and faſten'd thereto regularly, and at their proper Diſtances, that when their Leaves to come out, there may be no Confuſion.

Tranſplant all Sorts of Fruit-trees, where they are wanting, this being the moſt proper Seaſon for moiſt Land (in which it is not ſo well to plant in Autumn) but you muſt obſerve to work the Ground well, and break the Clods before planting, that the Earth may the better join to every Part of the Roots. The Heads of theſe Trees ſhould alſo be left on until they begin to puſh, when they muſt be carefully cut down, after the manner directed under the Article of *Planting*.

The latter End of this Month (if the Seaſon be mild) you muſt begin to graft Pears, Plums, Cherries, and other hardy Kinds of Fruit, being very careful that they are well clay'd, that the Wind can't enter to the Graft, upon which chiefly depends your Succeſs.

You may now ſow the Kernels and Stones of hardy Fruits for Stocks, to bud and graft the more generous Kinds upon, obſerving to cover them equally with Earth, that none may appear above-ground to entice the Mice or other Vermin to them, which often deſtroy whole Beds of Seeds, if they are not prevented.

In moiſt Weather clear your Fruit-trees from Moſs (where they are infeſted with it) which at this Seaſon may be eaſily done with an Iron Inſtrument ſhap'd like a Hough, and hollow'd in the middle to the Size of the Branches, which are to be ſcrap'd; ſo that there ſhould be three Sizes of theſe Inſtruments, which will be ſufficient for all the different Branches; and the Moſs being tender at this Time, may be eaſily rubb'd off.

The early Fruit-frame or Forcing-frame muſt now be duly attended to give them Air, as the Seaſon may require, as alſo to keep up the Heat, without which the tender Fruit will drop off, and come to nothing.

Fruits in prime, or yet laſting.

Pears; Winter Boncretien, Beſſy de Caſſoy, Citron d'Hyver, Winter Ruſſelet, Bugi, or Bergamot de Paſque, Lord Cheyne's Green Pear, Portail; and for baking, the Cadillac, Union, or Pickering, *Engliſh* Warden, and Black Pear of Worceſter.

Apples; Rennett Griſe, Aromatick Pippen, Golden Ruſſets, Nonpareil, Golden Pippen, Holland Pippen, *French* Pippen, *Kentiſh* Pippen, Stone Pippen, John Apple, Harvey Apple, Pile's Ruſſet, Wheeler's Ruſſet, Winter Pearmain, *with ſome* others of leſs Note.

Work to be done in the PLEASURE GARDEN.

If the Weather be mild, you may now plant out your choice Carnations into the Pots where they are to flower; in doing of which, you ſhould not take too much of the Earth from their Roots; and when they are planted, it will be proper to place the Pots in a warm Situation (but not too near Walls, or Pales, which will draw them up weak) and arch them over with Hoops, that in bad Weather they may be cover'd with Mats; for at this Seaſon they ſhould acquire Strength before the Heat comes on, otherwiſe they will not produce large Flowers.

You may yet ſow Auricula and Polyanthos-ſeeds in Tubs or Pots of light rich Earth, placing them where they may have the Morning Sun till *April*, when they muſt be remov'd into a more ſhady Situation, there to remain during the Summer Seaſon.

If your Auricula's in Pots were not freſh earth'd the laſt Month, that ſhould now be done, in the manner directed in *January*; for now their Flower-buds will begin to ſhew apace; ſo that if it be not done in a ſhort Time, their Flowers will not be improv'd by it.

Stir the Surface of the Ground of your Flower-beds, and clear them from Weeds, Moſs, and whatever Filth may appear thereon, which will be very ſerviceable to the Flowers, and add a Neatneſs to the Garden.

Dig and prepare your Ground in the Flower-Nurſery for ſowing of Seeds, and to receive Plants the next Month, when you will have much Buſineſs of different Kinds to do; ſo that if you do not get Things in Forwardneſs this Month, you will be ſo much hurry'd in the next, that many Things muſt be omitted, or but ſlightly perform'd.

Tranſplant Canterbury Bells, *French* Honeyſuckles, Daizies, Roſe-Campions, Fox-Gloves, Pinks, Sweet-Williams, Perennial Catch-fly, Campanula's, Thrift, Scarlet-Lychnis, Columbines, Starworts, Golden-rods, with many other fibroſe rooted Plants, into the Borders of your Pleaſure Garden where they are deſign'd to flower; but this is better to be don at *Michaelmas*, where the Ground is dry, becauſe the Plants will have taken good Root, and obtain Strength before the dry Weather of the Spring comes on, and ſo will produce a greater Quantity of Flowers.

In dry froſty Nights you muſt cover your Beds of choice Ranunculus's, Anemonies and Tulips with Mats, to protect them from the Injury of the Weather, otherwiſe they will be in danger of ſpoiling, at leaſt their Flowers will not be ſo fair, nor numerous, and many times the Roots are deſtroy'd by Froſt at this Seaſon.

You may now tranſplant all Sorts of hardy Flowering-trees and Shrubs, as Lilacks, Laburnums, Bladder Senna's, Scorpion Senna's, Roſes, Honeyſuckles, Jaſmines, *&c.* and moſt Sorts of Foreſt-trees may now be tranſplanted with Safety; but Evergreens ſhould not be remov'd till the Beginning of *April*, when they are juſt ready to puſh out their Buds, which is the ſafeſt Seaſon to tranſplant them in.

Plant *Dutch*-box for Edgings to Borders; but it is a better Seaſon in *September*, eſpecially for dry Ground, becauſe it will be firmly rooted before the Drought of the Spring, which is often very deſtructive to ſuch Edgings as are late planted.

Break up your Gravel-Walks, and turn them; but do not rake them until the middle of next Month, by which Time they will be well ſettled.

The latter End of this Month you ſhould take and clean the Quarters of your Wilderneſs, becauſe the Flowers which are under the Trees will now begin to blow; ſo that there is a Neceſſity of making the Place clean, that it may appear ſightly. The Edges of the Graſs-Walks ſhould alſo be cut by a Line, that they may be even; and the Water-Tables on the Sides of the Walks ſhould be dug and rak'd, that they may be clear from Weeds and Moſs.

Make Hot-beds for your tender annual Flowers, which require to be brought forward early in the Spring, which otherwiſe are in Danger of not ripening their Seeds; as the Amaranthus's, Amaranthoides, Double-flowering Stramonium, Double-ſtrip'd Balſamine, with ſome others. You muſt alſo plant ſome Tuberoſes on a Hot-bed to come early in the Summer, provided you did not do it the laſt Month.

Plants now in Flower in the PLEASURE GARDEN.

Winter Aconite, Helleboraſter or Bear's-foot, True Black Hellebore, Green-flower'd Black Hellebore, Snow-drops, ſeveral Sorts of Spring Crocus's, Single-Anemonies, Spring Cyclamen, Great Snow-drop, Early White and Blue Hyacinths, Starry Hyacinth, *Perſian* Iris, Hepatica's, Single Wallflower, Early Tulips, Polyanthus's, Fennel-leav'd Perennial Adonis, Omphaloides pumila Verna, *&c.* with ſome others.

Hardy Trees and Shrubs now in Flower.

Lauruſtinus two or three Sorts, Mezerion Red and White, Spurge Laurel, *Spaniſh* Travellers-joy, Cherry-Plum, White-flower'd Almond, Cornelian Cherry, Filberts, Hazle-Nuts, and ſome others.

Work to be done in the NURSERY.

You may now tranſplant moſt Sorts of hardy Foreſt Trees and flowering Shrubs, provided the Seaſon be favourable, otherwiſe it will be better to defer it a little later. If you did not take off the Layers of Elms, Limes, and other hardy Foreſt-trees, or Shrubs, at *Michaelmas*, it ſhould now be done, planting them into the Nurſery in Rows three Feet aſunder, and eighteen Inches Diſtance in the Rows; where they may ſtand five or ſix Years to obtain Strength, in order for tranſplanting where they are to remain.

The Ground where you intend to plant a Nurſery of Evergreens ſhould now be carefully trenched, obſerving to cleanſe it from the Roots of all noxious Weeds, particularly Couch-graſs, which if left in the Ground, will mix with the Roots of the new planted Trees, and prove very injurious to them, and will be very difficult to get out again.

Where the Ground between the Trees in the Nurſery was not dug the former Month, it ſhould now be done, obſerving (as was before directed) not to injure their Roots; but ſhorten ſuch as were extended far from their Stems, in order to force out young Roots nearer, that they may be fitted for tranſplanting: This ſhould be particularly obſerved in Hollies and other Evergreens, which ſhould be conſtantly dug round every Year, cutting off all downright Roots, and ſuch as extend themſelves from the Plants, which will occaſion a great Quantity of ſtrong Fibres to be ſent forth near their Stems, and render them much ſafer to remove, becauſe theſe will maintain a Ball of Earth to their Roots, when they are carefully taken up, the Want of which renders it almoſt impracticable to tranſplant ſuch Trees as have remain'd many Years, without having been dug round.

You muſt now plant *Cheſnuts*, and ſow the *Seeds*, *Maſt* or *Berries* of other hardy Trees and Shrubs, being careful to cover them with Earth, for if any of them are left expoſed, it will intice Mice and other Vermin, whereby your Seeds will be eaten up, and your whole Seminary deſtroyed.

Toward the latter End of this Month, you ſhould cut off the Heads of your Stocks which were budded with Fruit the preceding Summer, about four or five Inches above the Buds, always obſerving to cut the Stock ſloping from the Bud, that it may not be injured by the flowing of the Sap from the wounded part of the Stock.

If this Month proves mild, you muſt graft *Cherries*, *Plums*, *Pears*, *Apples*, and other hardy Fruits; but if there are hard Froſts and drying Winds, it will be better to defer it a little later, for ſuch Weather is very deſtructive to Grafts.

You may now plant Cuttings of Currants, Gooſeberries, and other Trees which will grow from Cuttings, in ſhady Borders, obſerving to cloſe the Earth well about them, otherwiſe the drying Winds of *March*, will penetrate the Ground and deſtroy them.

Make Layers of all your hardy exotick Trees, which you want to increaſe in this Month, after all hard Froſts are over; for ſome of theſe are too tender to be laid in Autumn, the Wet of the Winter ſucceeded by Froſt being very deſtructive to moſt of theſe tender Plants, when laid.

Work to be done in the GREEN-HOUSE *and* STOVE.

If the Weather be mild, and the Air ſoft, you ſhould begin to let Air into your Green-houſe; but this muſt be done with Care at firſt, and never open the Glaſſes when the Wind is ſharp, at leaſt not on the Side on which the Wind blows; for a ſharp Air at this Seaſon will do great Damage to your Plants now they are tender. Myrtles, Oranges, Geraniums, and other hardy Plants, muſt now be frequently refreſh'd with Water; but let them have it moderately and often, too much Wet at this Seaſon being very injurious to them.

Pick off all dead and decay'd Leaves from your Plants, and ſtir the Surface of the Earth in the Pots or Tubs, clearing them from Weeds, and if you add a little very rotten Neats-dung upon the Tops of the Tubs or Pots, it will be ſerviceable to the Plants. You ſhould at the ſame time bruſh down all Cobwebs, and make the Houſe clean in every Part, Neatneſs being as neceſſary to the Health of Plants as of Animals.

Make Hot-beds to ſow tender Exotick Seeds upon, which are brought from very hot Countries, obſerving to work the Dung well, that the Beds may retain their Heat, and ſettle equally; for when the Dung is not equally ſtirr'd, and beat down with the Fork, it will ſettle in Holes, which is a great Fault in theſe Beds, becauſe when they are water'd the Water will run into the Holes and cauſe thoſe Places to be over-wet, when the other Parts of the Bed will receive little or no Benefit from it.

If any of your Orange-trees have ſuffer'd by ill Management, ſo much that their Heads are decay'd, you ſhould now prune them cloſe, and ſhift them into freſh Earth, and then prepare a moderate Hot-bed in a Glaſs Stove, into which they muſt be plac'd to force them out early in the Spring, that their Shoots may have Time to harden before Winter. But in ſhifting them you ſhould be careful to cut off all mouldy or decay'd Roots, and to cleanſe both Roots and Stems from any Filth they may have contracted: And when they are plac'd in the Hot-bed, you muſt be careful that the Heat be not too great, and frequently refreſh them with Water, not only to their Roots, but over every part of their Stems, which will ſupple their Barks, and cauſe them to puſh out vigorouſly. But when the Sun begins to ſhine with great Force, the Glaſſes of the Houſe ſhould be ſhaded with Mats or Cloths, otherwiſe it will ſcorch their Leaves, and dry the Bark of the Shoots; ſo that they will greatly ſuffer, if too much expos'd thereto; but this heading and forcing of Orange-trees ſhould not be too often practis'd on them, for it will weaken the Trees when repeated too frequently; therefore where they are not in a very bad Condition, it will be the better way to let them be ſhifted if there be occaſion, and place them in a ſhady Situation when they are brought out of the Green-houſe, where, if they are duly ſupplied with Water, they will break out again very ſtrong and well.

The Bark in the Beds of the Stoves will now require to be ſtirr'd up, and ſome freſh Bark added to them to renew their Heat, which will now begin to decline, and, if not timely renew'd, the Plants will ſuffer greatly: But this muſt be done in a warm Day, when the Air is ſoft; for in very cold Weather the Glaſſes muſt not be open'd, ſo that the Bark could not be then put in.

Waſh and clean the Leaves of your Coffee-trees and other woody Plants in the Bark-Stove from Inſects and Filth, and pick off all decay'd Leaves, which, if left on, would infect the Air of the Houſe. The Surface of the Earth in the Pots ſhould alſo be frequently ſtirr'd, to prevent its binding, and muſt always be kept free from Weeds.

The Anana Plants will now ſhew their Fruit apace, ſo that they ſhould be frequently water'd to bring them forward; and the Heat of the Stove muſt be kept up; for if that is ſuffer'd to decline, the Plants will change their Colour, and the Fruit will be render'd ſmall and worth little. Toward the End of this Month you muſt prepare ſome freſh Bark to make the Summer-beds for the Anana's, into which they ſhould be plung'd ſome time the next Month.

The Aloes, Euphorbiums, Torch-Thiſtles, Melon-thiſtles, and other tender ſucculent Plants, ſhould have very little Water given them at this Seaſon; but the Ficoides's, Sedums, Cotyledons, and other hardy Kinds muſt be frequently refreſh'd: But theſe muſt not have it in too large Quantities, becauſe much Wet at this Seaſon will often rot them. You muſt now make freſh Hot-beds of Tan, to ſow the Seeds of ſuch tender Exoticks as are annual, or that you may have received from abroad; into which you ſhould plunge ſmall Pots filled with light freſh Earth, that the Mould may be warm before the Seeds are ſown. This Method of ſowing the Seeds in Pots, is preferable to any other, becauſe the Plants may be ſhaken out of the Pots, when they are fit to tranſplant, with the Earth about their Roots, whereby they will be in little Danger of ſuffering, becauſe their Roots will be preſerved intire.

Plants now in Flower in the GREEN-HOUSE *and* STOVE.

Indian yellow Jaſmine, Ilix-leav'd Jaſmine, *Spaniſh* Jaſmine, Geranium with a ſcarlet Flower, Geranium with a variegated Flower, ſeveral Sorts of Ficoides's, Polygala arboreſcens, Aleppo Cyclamens, Senecio Africanus folio retuſo, Doria Africana atriplicis folio, Doria Africana Coronopi folio, Hermannia Alni folio, Aloes of ſeveral Sorts, Anemonoſpermos's, Turnera, Euphorbiums, Cotyledon with broad cut Leaves, *Malpighia mali punici facie*, with ſome others.

FENCES. In hotter Climates than *England*, where they have not Occaſion for Walls to ripen their Fruit, their Gardens lie open, where they can have Water-Fences and Proſpects; or elſe they bound their Gardens with Groves, in which are Fountains, Walks, *&c.* which are much more pleaſing to the Sight than a dead Wall: but in colder Countries and in *England* we are oblig'd to have Walls to ſhelter and ripen our Fruit, altho' they take away much from the pleaſant Proſpect of the Garden.

Since therefore we are under a Neceſſity to have Walls to ſecure our Gardens from the Injury of Winds, as well as for the Conveniency of Partitions or Incloſures, and alſo to ripen our Fruit, Brick-Walls are accounted the warmeſt and beſt for Fruit: And theſe Walls being built Pannel-wiſe, with Pillars at equal Diſtances, will ſave a great deal of Charge; in that the Walls may be built thinner, than if they were built plain without theſe Pannels; for then it would be neceſſary to build them thicker every where: and beſides, theſe Pannels make theſe Walls look the handſomer.

Stone-Walls are to be preferr'd to thoſe of Brick, eſpecially thoſe of ſquare-hewn Stones. Thoſe that are made of rough Stones, tho' they are very dry and warm, yet, by reaſon of their Unevenneſs, are inconvenient to nail up Trees to, except Pieces of Timber be laid in them, here and there, for that Purpoſe.

But in large Gardens it is better to have the Proſpect open to the Pleaſure-Garden, which ſhould be either ſurrounded with Water, or a Foſſe, ſo that from the Garden the adjacent Country may be view'd.

A Kitchen-Garden, if rightly contriv'd, will contain Walling enough to afford a Supply of ſuch Fruits as require the Aſſiſtance of Walls for any Family; and this Garden being ſituated on one Side of the Houſe, may be ſurrounded with Walls, which will ſcreen the Kitchen-herbs from the Sight of Perſons in the Pleaſure-Garden; and being lock'd up intire, the Fruit will be much better preſerv'd than it can be in the publick Garden: And the having too great a Quantity of Walling, is often the Occaſion that ſo many ſcandalous Trees are frequently to be ſeen in large Gardens, where there is not due Care obſerv'd in their Management.

And beſides, the Borders of Pleaſure-Gardens are generally too narrow for the Roots of Fruit-Trees, as will be ſhewn in its proper Place.

The Height of Garden-Walls ſhould be twelve Feet, which is a moderate Proportion; and if the Soil be good, it may in Time be well furniſh'd with bearing Wood in every Part, eſpecially that Part planted with *Pears*, notwithſtanding the Branches being train'd horizontally from the Bottom of the Walls.

I would recommend the *White Thorn*, the *Holly*, the *Black Thorn*, and *Crab*, for outward Fences to a good Ground; but I do not approve of the intermixing them.

The *White Thorn* is the beſt *Quick* to plant; becauſe it is the moſt common, and may be clipp'd ſo as to render it the cloſeſt and hardieſt Fence of any other Tree, and being very durable, is preferr'd to all others for outward Fences, or for the Diviſion of Fields, where they are expoſed to Cattle, *&c.*

The *Black Thorn* and *Crab* make very good Fences, and are to be rais'd as the *White Thorn*. But if the Kernels of *Apples* or *Crabs* be ſown, it is beſt to ſow the *Pommace* with them, and they will come up the ſooner, *i. e.* the firſt Year.

If *Crab*-Stocks be planted while young, in the ſame Manner as *Quick*, they make excellent Hedges, and ſo will ſome Sorts of *Plums*.

The *Black Thorn* is not accounted ſo good for *Fences* as the *White Thorn*, becauſe it is apt to run more into the Ground, and is not certain as to the Growing; eſpecially if the Plants are not ſet very young: But then, on the other Hand, the Buſhes are by much the better, and are alſo more laſting than the *White Thorn*, or any other, for dead Hedges, or to mend Gaps: Nor are they ſubject to be cropt by Cattle, as the others are. The richer the Mould is, the better they will proſper; but yet they will grow on the ſame Sort of Soil that the *White Thorn* does.

The *Holly* will make an excellent *Fence*, and is preferable to all the reſt: But it is difficult to be made to grow at the firſt, and is a ſlow Grower; but when once it does grow, it makes amends by its Height, Strength, and Thickneſs.

It is raiſed either of *Sets* or *Berries*, as the *White Thorn* is; and will lie as long in the Ground before it comes up. It delights moſt in ſtrong Grounds, but will grow upon the drieſt Gravel, amongſt Rocks or Stones.

The *Berries* lie till the ſecond Spring before they come up, therefore they ſhould be prepar'd before they are ſown. (For this, ſee the Article *Aquifolium.)* It will be beſt to ſow 'em in the Place where you deſign they ſhould grow; and they ſhould be well weeded both before they come up, and afterwards.

French Furs will alſo do well upon dry ſandy Banks, where few other Plants will grow; but they muſt be kept very clean at the Bottom, and cut thin, and never ſuffer'd to grow too high: Nor ſhould they be cut in dry Weather, nor late in Autumn, nor early in the Spring; the doing either of which, is ſubject to make it die in Patches, which is irrecoverable: Nor will it ever break out again from old Wood, if cut cloſe in, after it has been ſuffer'd long to grow out.

Fences may likewiſe be made of *Elder*: If the Soil be any Thing good, you may ſtick Sticks of *Elder*, or Truncheons ten or twelve Feet long, ſlopewiſe in your Bank, ſo as to make Chequer-work, and they will make a *Fence* for a Garden the quickeſt of any Thing, and be a good Shelter.

Elder planted on a Bank, the Side of which is waſh'd with a River or Stream, will make an extraordinary *Fence*, and will preſerve the Bank from being undermin'd by the Water; becauſe it is continually ſending Suckers from the lower Roots, which is of great Advantage where the Stream waſhes away the Bank.

For middle *Fences* in a Garden, the *Yew* is the more tonſile, governable, and durable Plant.

For ſurrounding Wilderneſs Quarters, *Elm*, *Lime*, *Hornbeam*, and *Beach* are very proper.

FENNEL. *Vide* Fœniculum.

FENNEL-FLOWER. *Vide* Nigella.

FERRUM EQUINUM; [ſo call'd, becauſe the Huſk and Seed are ſo bended as to reſemble a Horſe-ſhoe] Horſe-ſhoe Vetch.

The *Characters* are;

It hath a papilionaceous Flower, which is ſucceeded by a flat Pod, diſtinguiſh'd into Joints reſembling a Half-Moon, or an Horſe-ſhoe, containing Seeds of the ſame Form.

The *Species* are;

1. FERRUM EQUINUM *ſiliqua ſingulari. C. B.* Horſe-ſhoe Vetch, with a ſingle Pod.

2. FERRUM EQUINUM *ſiliqua multiplici. C. B.* Horſe-ſhoe Vetch, with many Pods.

3. Ferrum Equinum *Germanicum, ſiliquis in ſummitate. C. B.* Common Horſe-ſhoe Vetch.

There are ſome other Varieties of this Plant, which are preſerv'd in curious botanic Gardens; but it is rare that any of them are propagated, except for Variety-ſake, they having no great Beauty. The two firſt Species are brought from Abroad; but the third Sort grows wild upon Chalky Hills in divers Parts of *England*.

They may be propagated by ſowing their Seeds in *March* upon a dry Soil, in the Places where they are to remain; for they do not well bear Tranſplanting. The Diſtance they ſhould be allow'd, ought to be at leaſt a Foot from each other; for they ſpread upon the Ground, and will cover that Space: Theſe produce their Flowers in *June*, and perfect their Seeds in *Auguſt* and *September*.

FERULA; [takes its Name of ***Ferendo***, Lat. becauſe the Stalks of this Plant are made uſe of in ſupporting the Branches of Trees; or of ***Feriendo***, becauſe in Old Time, Sticks or Staves were made of them with which School-Maſters uſed to correct their Scholars] Fennel-Giant.

The *Characters* are;

It hath a large ſucculent Milky Root; the Stalks are ſpongy and fill'd with Pith; the Flowers conſiſt of many Leaves, which expand in form of a Roſe, *and grow in an Umbel; each Flower is ſucceeded by two large Oval-ſhap'd flat Seeds, which are very thin, and for the moſt Part turn black when they are ripe; to which may be added, The Leaves are like thoſe of* Fennel.

The *Species* are;

1. Ferula *major, ſeu fœmina Plinii. M. Umb. Pliny's* Female Fennel-Giant.
2. Ferula *galbanifera. Lob. Obſ.* Broad-leav'd Fennel-Giant.
3. Ferula *Tingitana, folio latiſſimo lucido. H. Edin.* Broad-leav'd ſhining Fennel-Giant from *Tangier*.
4. Ferula *Tingitana, folio anguſto lucido. H. L.* Narrow-leav'd Fennel-Giant from *Tangier*.
5. Ferula *tenuiore folio.* Narrow-leav'd Fennel-Giant.
6. Ferula *Africana galbanifera, folio & facie liguſtici. Par. Bat. African* Fennel-Giant, with the Face and Leaf of Lovage.
7. Ferula *Africana galbanifera, folio Myrrhidis. H. Amſt. African* Fennel-Giant with a Seſeli Leaf.

There are ſeveral other Varieties of this Plant, which are preſerv'd in curious botanic Gardens; but as they are of no great Uſe or Beauty, I ſhall paſs them over in this Place.

The firſt of theſe Plants is pretty common in the *Engliſh* Gardens: This, if planted in a good Soil, will grow to the Height of ten or twelve Feet and more, and divides into many Branches, ſo that it ſhould have a great deal of Room: For if it be planted too near to other Plants, it will over-bear and deſtroy them. It dies to the Surface every Autumn, and riſes again the ſucceeding Spring. The Flowers are produc'd in *June*, and the Seeds are ripe in *September*.

Mr. *Ray* ſays, That the People of *Sicily* uſe the Pith of this Plant for Tinder to light their Fires. And if this was practis'd by the Antients, we may eaſily gueſs why the Poets feign'd, that *Prometheus* ſtole Fire from Heaven, and carry'd it to the Earth in an hollow *Ferula*.

The ſecond, ſixth, and ſeventh Sorts are ſuppos'd by ſome Authors to afford *Galbanum*, which, they ſay, is an Exudation from ſome of theſe Plants: But this at preſent is not determin'd; for, if any of the three, the ſeventh is thought to be the beſt.

Theſe Plants are all very hardy; except the ſixth and ſeventh Sorts, which being Natives of a warm Country, do require to be hous'd in Winter. They are all propagated by ſowing their Seeds, which ſhould be done ſoon after they are ripe: But if they are kept until Spring, they ſeldom grow until the following Spring; they muſt be ſown very early, and in a ſhady Situation, otherwiſe the Seeds are ſubject to miſcarry. They delight in a light, moiſt Soil, and muſt be planted at leaſt two Feet and an half aſunder; for they ſpread very far. The Roots will abide many Years, if ſuffer'd to remain undiſturb'd: But if they are tranſplanted when old, they ſeldom thrive well afterwards. Theſe being Plants only for Curioſity, one of each Sort is ſufficient for a Garden; ſince they are of no great Beauty, and require much Room.

The ſixth and ſeventh Sorts ſhould be ſown ſoon after the Seeds are ripe, in a Pot of good Earth, which ſhould be plac'd under a Hot-bed Frame during the Winter-Seaſon, to preſerve it from the Froſts: And when the Plants are come up in the Spring, they ſhould be tranſplanted each into a ſeparate Pot, and may be expos'd in Summer, but in Winter ſhould be defended from Froſts. They muſt be ſhifted into larger Pots, as they increaſe in Bulk. The beſt Seaſon for removing them is in *September*, before they are hous'd. They require frequent Waterings, and to have as much Air as poſſible in mild Weather.

FICOIDEA. [This Plant is ſo called from its Reſemblance to the Ficoides.]

The *Characters* are;

It hath a ſtamineous Flower, whoſe Calyx is divided into five roundiſh Segments: When the Flower is paſt, the Pointal (which is terminated by five Threads) becomes a five-corner'd Fruit; which when ripe opens into five Cells, each of which is filled with ſmall Seeds.

The *Species* are;

1. Ficoidea *procumbens, portulacæ folio. Acad. Reg. Scien.* Trailing Ficoidea, with a purſlain Leaf.
2. Ficoidea *Hiſpanica annua, folio longiore. Vaill.* Annual *Spaniſh* Ficoidea, with a longer Leaf.

Theſe two Plants are propagated by Seeds, which ſhould be ſown on a Hot-bed in the Spring, and when the Plants are come up, they ſhould each be tranſplanted into a Half-penny Pot, and plunged into another moderate Hot-bed, obſerving to let them have Air in proportion to the Warmth of the Seaſon; and they muſt be frequently refreſhed with Water. Toward the End of *June*, they ſhould be inured to bear the open Air by degrees; and in *July* they may be removed into the open Air, and placed amongſt Ficoides's and other hardy ſucculent Plants, where they will flower, and produce ripe Seeds in Autumn.

FICOIDES; [is ſo call'd of *Ficus*, Lat. a *Fig*, becauſe the Fruit of it reſembles a Fig; it is alſo call'd *Aizoides*, of Αιζωον, Gr. i. e. *Ever-living*, becauſe it is always green, and reſembles the *Sedum*] Fig-Marygold.

The *Characters* are;

The whole Plant is ſucculent, and has the Appearance of Houſeleek: *The Leaves grow oppoſite by Pairs; the Cup of the Flower is fleſhy, and divided into five Parts almoſt to the Bottom; the Flower conſiſts of many Leaves, which are divided into ſmall Parts, and do expand in form of a* Marygold; *the Flower is ſucceeded by a ſucculent Fruit, which is divided into five or more Cells, which are full of ſmall Seeds.*

The *Species* are;

1. Ficoides *ſeu ficus Aizoides, Africana major, procumbens triangulari, folio enſiformi. H. L. Boerh. Ind.* Great trailing *African* Ficoides, with a triangular Sword-ſhap'd Leaf.
2. Ficoides *ſeu ficus Aizoides, Africana major, procumbens triangulari, folio fructu maximo eduli. Ficus Hottentottorum, vulgo. H. L.* Great trailing *African* Ficoides, with a triangular Sword-ſhap'd Leaf, and a large eatable Fruit, *commonly call'd*, the *Hottentot* Fig.
3. Ficoides *Afra, caule lignoſo erecta, folio triangulari, enſiformi ſcabro, flore luteo magno. Boerh. Ind.* Upright *African* Ficoides, with a woody Stalk, and a triangular rough Sword-ſhap'd Leaf, and a large yellow Flower.
4. Ficoides *Afra, arboreſcens erecta, folio triangulari, longiſſimo confertim nato purpuraſcente, flore luteo magno. Boerh. Ind.* Upright Tree-like *African* Ficoides, with a long triangular Leaf, and a large yellow Flower, *commonly call'd*, Pink-leav'd Ficoides.
5. Ficoides *Afra, folio triangulari enſiformi, glauco craſſo, ad margines laterales paucis, inermibus ſpinis aculeato, flore in longo pedunculo aureo. Boerh. Ind. African* Ficoides, with a thick triangular Sword-ſhap'd Leaf, arm'd with Spines on the Edges, and a yellow Flower growing upon a long Foot-ſtalk, *commonly call'd*, the Dog's-Chap Ficoides.
6. Ficoides *Afra, folio triangulari enſiformi, craſſo brevi, ad margines laterales multis, majoribuſque ſpinis aculeato, flore aureo ex calyce longiſſimo. Boerh. Ind. African* Ficoides, with a triangular Sword-ſhap'd Leaf, having many large Spines upon their Edges, and a yellow Flower with a long Calyx, *commonly call'd*, the prickly Dog's-Chap Ficoides.
7. Ficoides *Afra, folio triangulari ſecuris forma, flore aureo ſtellato. Boerh. Ind. African* Ficoides, with a triangular Hatchet-ſhap'd Leaf, and a yellow ſtarry Flower, *commonly call'd*, the Stag's-Horn Ficoides. This Sort expands its Flowers only in the Evening.
8. Ficoides *Afra, folio triangulari longo, marginis inferioris ſupremo aculeato, flore violaceo. Boerh. Ind.* African

Ficoides, with a long triangular Leaf, having Spines at the Extremity on the under Part of the Leaves, and a Violet-colour'd Flower, *commonly call'd* the Daiſy-colour'd *Ficoides.*

9. FICOIDES *Africana fruteſcens perfoliata, folio triangulari glauco punctato, cortice lignoſo candido tenui. T. Ac. Reg.* Shrubby African *Ficoides*, with perfoliated, triangular, glaucous Leaves, and a ſlender, white, lignous Bark, *commonly call'd* the leſſer Horn'd *Ficoides.*

10. FICOIDES *Afra, folio triangulari glauco perfoliato breviſſimo, apice ſpinoſo. Boerh. Ind. flore purpureo.* African *Ficoides*, with a triangular, ſhort, perfoliate, glaucous Leaf, having Spines upon the Top, and a Purple Flower, *commonly call'd*, the large Horn'd *Ficoides.*

11. FICOIDES *Africana, aculeis longiſſimis, & foliatis naſcentibus ex alis foliorum. Tourn. Ac. Reg.* African *Ficoides*, with long Spines growing from the Wings of the Leaves.

12. FICOIDES *Afra, folio triangulari enſiformi breviſſimo, flore dilute purpuraſcente filamentoſo. Boerh. Ind.* African *Ficoides*, with a ſhort triangular Sword-ſhap'd Leaf, and a purpliſh-colour'd Flower.

13. FICOIDES, *ſeu ficus aizoides Africana, folio triangulari craſſo glauco brevi, ad tres margines aculeato. Boerh. Ind. flore purpuraſcente.* African *Ficoides*, with a ſhort, thick, glaucous, triangular Leaf, with three Spines on the Edges, and a purpliſh Flower.

14. FICOIDES *Afra folio triangulari, glauco breviſſimo craſſiſſimo, margine non ſpinoſo. Boerh. Ind. flore purpuraſcente.* African *Ficoides*, with a very ſhort, thick, triangular, glaucous Leaf, without Spines on the Edge, and a purpliſh-colour'd Flower.

15. FICOIDES *Afra, folio triangulari glauco breviſſimo craſſiſſimo, margine ſpinoſo, caule & flore purpureo.* African *Ficoides*, with a very ſhort, thick, glaucous Leaf, with Spines upon the Edge, and a purple Stalk and Flower.

16. FICOIDES *Afra fruticans, folio triangulari ſcabro tenui, flore violaceo. Boerh. Ind.* African ſhrubby *Ficoides*, with a triangular, rough, narrow Leaf, and a Violet-colour'd Flower.

17. FICOIDES *Afra, folio triangulari viridi longo aſpero, flore violaceo. Boerh. Ind.* African *Ficoides*, with a long green, rough, triangular Leaf, and a Violet-colour'd Flower.

18. FICOIDES *Afra, folio triangulari craſſo ſucculentiſſimo. Boerh. Ind. flore aureo.* African *Ficoides*, with a thick, ſucculent, triangular Leaf, and a yellow Flower.

19. FICOIDES *Afra, folio triangulari longo ſucculento, caulibus rubris. Boerh. Ind. flore luteo.* African *Ficoides*, with a long, ſucculent, triangular Leaf, red Stalks, and a yellow Flower.

20. FICOIDES, *ſeu ficus aizoides Africana erecta arboreſcens lignoſa, flore radiato, primo purpureo, dein argenteo, interdiu clauſo, noctu aperto. Boerh. Ind.* African upright Tree-like *Ficoides*, with a radiated Flower, firſt of a Purple, and afterwards a Silver Colour, opening in the Night, but clos'd in the Day.

21. FICOIDES *Afra arboreſcens, folio tereti, flore candido, noctu aperto, interdiu clauſo. Boerh. Ind.* African Tree-like *Ficoides*, with a taper Leaf and white Flower, opening in the Night, but ſhut in the Day.

22. FICOIDES *Afra arboreſcens, folio tereti glauco, apice purpureo, craſſo. Boerh. Ind. flore violaceo.* African Tree-like *Ficoides*, with a thick, taper, glaucous Leaf, tipt with Purple, and a Violet-colour'd Flower.

23. FICOIDES *Afra, folio tereti, procumbens, flore coccineo. H. L.* African trailing *Ficoides*, with a taper Leaf, and a ſcarlet Flower.

24. FICOIDES, *ſeu ficus aizoides Africana, folio longo tenui, flore aurantio. Boerh. Ind.* African *Ficoides*, with a long narrow Leaf, and an Orange-coloured Flower.

25. FICOIDES *Afra fruticoſa, caule lanuginoſo, folio tereti parvo brevi guttato, flore violaceo. Ind.* African ſhrubby *Ficoides*, with a woolly Stalk, a ſmall, taper, ſpotted Leaf, and Violet-colour'd Flower.

26. FICOIDES *Afra fruticoſa, caule lanugine argentea ornato, folio tereti parvo longo, guttulis argenteis quaſi ſcabro, flore violaceo. Boerh. Ind.* African ſhrubby *Ficoides*, with a white woolly Stalk, a long, taper, Silver-ſpotted, rough Leaf, and a Violet-coloured Flower.

27. FICOIDES, *ſeu ficus aizoides, Africana, folio variegato aſpero, ad apicem ſtella ſpinoſa ornato, flore violaceo. Boerh. Ind.* African *Ficoides*, with a rough Party-coloured Leaf, tip'd with a Star of Spines, and a Violet-coloured Flower.

28. FICOIDES *Afra lignoſa, folio tereti aſpero, ad apicem ſtella ſpinoſa, flore violaceo.* African woody *Ficoides*, with a taper rough Leaf, tip'd with a Star of Spines, and a Violet-coloured Flower.

29. FICOIDES, *ſeu ficus aizoides Africana erecta, tereti folio, floribus albis umbellatis. Par. Bat.* Upright African *Ficoides*, with a taper Leaf, and white Flowers, growing in an Umbel.

30. FICOIDES *folio tereti, caule viridi ramoſiſſimo, flore parvo candido.* African *Ficoides*, with a taper Leaf, a green branching Stalk, and a ſmall white Flower.

31. FICOIDES *Africana, folio tereti longo tenui guttulis argenteis, flore parvo purpuraſcente, radice craſſiſſima.* African *Ficoides*, with a long taper Leaf ſpotted with white, a ſmall purpliſh Flower, and a thick knobbed Root.

32. FICOIDES *Africana humilis, folio tereti craſſo ſucculento, flore ſulphureo, pedunculo brevi.* Dwarf African *Ficoides*, with a thick taper ſucculent Leaf, and a Sulphur-colour'd Flower, with a ſhort Foot-ſtalk, *commonly call'd*, the Quince-leav'd *Ficoides.*

33. FICOIDES *Africana, procumbens, folio tereti longo, flore violaceo.* African trailing *Ficoides*, with a long taper Leaf, and Violet-colour'd Flower.

34. FICOIDES *Afra acaulos, foliis latiſſimis craſſis lucidis conjugatis, flore aureo ampliſſimo. Tourn. Ac. Reg.* African *Ficoides* without Stalks, and with broad thick ſhining Leaves growing by Pairs, and a large yellow Flower.

35. FICOIDES *Afra acaulos, foliis latiſſimis craſſiſſimis lucidis conjugatis, flore aureo amplo, ſine pedunculo. Boerh. Ind.* African *Ficoides* without Stalks, and broad thick ſhining Leaves growing by Pairs, and a large yellow Flower without Foot-ſtalks.

36. FICOIDES *Afra foliis latiſſimis craſſis lucidis cruciatim poſitis. Boerh. Ind.* African *Ficoides*, with broad thick Leaves, growing croſs-wiſe.

37. FICOIDES *Africana procumbens, foliis latis craſſis cruciatim poſitis, flore albo, medio purpuraſcente.* African trailing *Ficoides*, with broad thick Leaves growing croſs-wiſe, and a white Flower with a purpliſh Middle.

38. FICOIDES *Africana procumbens, foliis latis conjugatis, flore candido.* African trailing *Ficoides*, with broad Leaves growing by Pairs, and a white Flower.

39. FICOIDES *Africana, folio plantaginis undulato, micis argenteis adſperſo. Tourn. Ac. Reg.* African *Ficoides*, with a wav'd Plantain Leaf cover'd with Silver Drops, *commonly call'd* the Diamond *Ficoides.*

40. FICOIDES *Hiſpanica annua, Lychnidis folio. Jeſſ.* Spaniſh annual *Ficoides* with a Campion Leaf.

41. FICOIDES *Canarienſis procumbens, portulacæ folio. Jeſſ.* Canary trailing *Ficoides*, with a Purſlain Leaf.

42. FICOIDES *Neapolitana, flore candido. H. L. Neapolitan* Ficoides, with a white Flower, commonly called *Egyptian Kali.*

43. FICOIDES *folio viridi triangulari tenuiore, flore luteo in extremitate rubente. Schw. Cat.* Fig-marygold, with a narrow green triangular Leaf, and a yellow Flower with red Tops.

44. FICOIDES *ſeu Ficus aizoides Africana, folio viridi, mici quaſi glaciatis ſplendentibus ornato, flore coccineo. Boerh. Ind* 1. *African* Ficoides with green Leaves, beſet with ſhining glaſs-like Drops, and a ſcarlet Flower.

45. FICOIDES *Africana, folio calamiforme, flore flaveſcente. African* Ficoides, with a quill-ſhaped Leaf, and a yellowiſh Flower.

46. FICOIDES *Africana procumbens, foliis ſempervivi congeſtis, flore candido. African* trailing Ficoides, with houſleek Leaves, and a white Flower.

47. FICOIDES *Africana procumbens, foliis ſempervivi expanſis, flore flaveſcente. African* trailing Ficoides, with an expanded houſleek Leaf, and a yellowiſh Flower.

The firſt thirty eight Sorts are all abiding Plants, and ma be propagated by planting Cuttings of any of the Kinds, eithe in *June* or *July*; obſerving to let them lie two or three Days or more, in a dry Place after they are cut off from the Plants before they are planted, according as they are more or leſs ſucculent: The Sorts that are woody, need only to be planted upon an old Hot-bed, ſhading and watering them according t the Heat and Drought of the Seaſon; but the ſucculent Kind ſhould be planted in Pots fill'd with light ſandy freſh Earth and ſhould be plung'd into a moderate Hot-bed, to facilitat their taking Root; and theſe ſhould have but little Moiſture eſpecially before they are rooted, for much Wet will certainly deſtroy them.

When the Plants have taken Root, which will be in about Month's Time, you ſhould expoſe them to the open Air gradually: Thoſe which were planted in Pots, may be draw out of the Hot-bed at firſt, and remov'd into a Glaſs Stove where they may be inur'd, by Degrees, to bear the Weather

Bu

But thoſe planted upon the old Hot-bed may remain unremov'd until *Auguſt*, when they ſhould be carefully taken up, and planted into Pots fill'd with light freſh ſandy Earth, and ſet in a Situation where they may enjoy the Morning Sun only, until they have taken freſh Root, when they may be expos'd to the open Air until the latter End of *September*, or the Beginning of *October*; at which time they muſt be remov'd into the Conſervatory, which ſhould be a light airy Glaſs-caſe, ſo built and contriv'd as to admit of a large Portion of free Air whenever the Weather is mild; but in hard froſty Weather, the Cold may be excluded. The Structure of this will be defin'd under the Article *Stove*, to which I ſhall refer the Reader.

During the Winter-ſeaſon you muſt carefully obſerve to open the Glaſſes every Day when the Weather is mild; for if you keep them cloſely ſhut up, the Plants will grow ſickly, and drop their Leaves. You muſt alſo obſerve to pick off all decay'd Leaves as often as they appear, which, if ſuffer'd to remain upon the Plants, would communicate a Diſtemper to them, and be very apt to rot them. You ſhould alſo give them frequent Waterings in mild Weather, eſpecially ſuch of 'em as are woody: but do not give 'em too much at once; for when the Earth, in Pots which are placed in the Houſe, is too much ſaturated with Moiſture, it will not dry again during the Winter-ſeaſon, for want of the Benefit of the Sun and Air, which are the two great Inſtruments in diſſipating Humidity; and this is often the entire Deſtruction of the Plant: whilſt on the other hand, ſome People, out of too great Care to theſe Plants, let them ſuffer for want of Water and free Air in Winter, under a Notion of their being ſo very tender as to be impatient of the leaſt Cold or Moiſture: whereas in fact, they are very hardy, and are ſeldom deſtroy'd with leſs Cold than hard Froſt; for I have had ſome Sorts endure the open Air in a warm Border for two or three Winters which prov'd mild; and ſuch of theſe Plants as had thus endured the Cold, produced a much greater Quantity of Flowers, than thoſe which had been preſerv'd in a Stove with great Care: and it hath been chiefly owing to our managing them tenderly in Winter, that we annually loſt ſo many of them; for ſince I have treated 'em in a different Manner, I have rarely loſt a ſingle Plant.

The 39th, 40th, and 41ſt Sorts are Annuals, and require to be ſown every Year. The 39th Sort is a very beautiful Plant, being all over ſet very thick with tranſparent Cryſtal-like Drops, as if cover'd with ſmall Iſicles; from whence it is, by ſome, call'd the *Froſty Ficoides*. The Seeds of this Plant ſhould be ſown very early in the Spring upon a good Hot-bed; and when the Plants are come up, they muſt be planted into ſmall Pots fill'd with freſh light ſandy Earth, and plung'd into another Hot-bed; and as that Hot-bed declines its Heat, they ſhould be remov'd into a third Hot-bed, which will bring them forward towards Flowering; and in *July* theſe Plants may be expoſed to the open Air by Degrees, by which Time their Flowers will appear, and be hereby render'd ſtrong, and capable to produce good Seeds: But you ſhould always confine in ſmall Pots ſuch Plants as you deſign for Seed, never ſuffering them to root thtough the Hole in the Bottom of the Pot into the Ground, which would occaſion their growing to be much larger and ſtronger Plants: But then their Strength would be diverted from the Seed-veſſels to nouriſh and produce ſtrong Shoots; ſo that it ſeldom happens that the ſtrongeſt Plants produce good Seeds. But if you would have ſome of theſe Plants of a large Growth, you ſhould ſhake them out of the Pots into an old Hot-bed of Tanners Bark, where their Roots and Branches will extend to a conſiderable Length. I have had one of theſe Plants in ſuch a Bed, which has ſpread above a Yard ſquare; and the Leaves and Branches were of a prodigious Size.

The Flowers of this Plant are of no great Beauty; but the Oddneſs of the whole Plant renders it worthy of a Place in every curious Garden.

The fortieth Sort is a Plant of little Beauty; and is ſeldom preſerv'd but in curious Botanick Gardens, for Variety.

The 1ſt, 2d, and 21ſt Sorts I have never yet ſeen flower, altho' there are many large Plants of each Kind in divers Gardens in *England*. I had one Plant of the 21ſt Sort, which had been planted into an open Border againſt a Wall, that was ſet very thick with Buds in almoſt every Part of the Plant, late in the Autumn 1726; but a ſudden, ſharp Froſt happening, deſtroy'd the whole Plant.

The 3d, 4th, 16th, 17th, 22d, 23d, 24th, and 25th Sorts do branch out and grow ſhrubby, and produce large Quantities of very beautiful Flowers; which being expanded in the Heat of the Day, afford a very agreeable Proſpect, and are well worth cultivating in every Collection of Plants, for their Beauty; as are all the Dwarf ſucculent Sorts, for their Oddneſs: and ſome of them produce beautiful Flowers, tho' not in ſuch Plenty as the former.

Theſe are, ſome or other of their Sorts, continually in Flower; but their chief Seaſon of flowering is from *April* to *September*; and many of them produce good Seeds: But as their Cuttings ſeldom fail to take Root, ſo they are rarely propagated by Seeds in *England*.

The 40th Sort is the *Kali*, the Aſhes of which is brought into *England*, and is an Ingredient in making clear Glaſs, as alſo in making the beſt hard Soap.

The forty ſecond Kind is an annual Plant, which ſhould be ſown on a Hot-bed early in the Spring; and when the Plants are come up, they ſhould be tranſplanted each into a ſeparate ſmall Pot, filled with light ſandy Earth, and plunged into a moderate Hot-bed of Tanners-bark; being careful to admit a large Share of Air to them in warm Weather, otherwiſe they will draw up weak. In *July* theſe Plants ſhould be inured to bear the open Air by degrees, when they ſhould be taken out of the Hot-bed, and placed in a warm Situation, where they will produce their Flowers; and if the Autumn proves favourable, will perfect their Seeds. This is the *Egyptian Kali*, or Glaſs-wort, whoſe Aſhes is ſo uſeful in making of Glaſs and hard Soap.

The other Sorts are propagated by Cuttings, as above directed.

FICUS; the Fig-tree.

The *Characters* are;

The Flowers, which are always incloſed in the Middle of the Fruit, conſiſt of one Leaf, and are Male and Female in the ſame Fruit: The Male Flowers are ſituated toward the Crown of the Fruit; and the Female, which grow near the Stalk, are ſucceeded by ſmall hard Seeds: The intire Fruit is, for the moſt part, turbinated and globular, or of an oval Shape, is fleſhy, and of a ſweet Taſte.

The *Species* are;

1. Ficus *ſativa, fructu violaceo longo, intus rubente. Tourn.* The long blue Fig.
2. Ficus *ſativa, fructu oblongo albo mellifluo. Tourn.* The long white Fig.
3. Ficus *ſativa, fructu præcoci albidi fugaci. Tourn.* The early white Fig, *by ſome falſly call'd the Marſeilles* Fig.
4. Ficus *ſativa, fructu globoſo albo mellifluo. Tourn.* The great round white Fig.
5. Ficus *ſativa, fructu parvo fuſco, intus rubente. Tourn.* The ſmall brown Fig.
6. Ficus *ſativa, fructu longo majori nigro, intus purpuraſcente. Tourn.* The great long black Fig.
7. Ficus *ſativa, fructu globoſo fuſco, intus rubente.* The *Brunſwick* Fig.
8. Ficus *ſativa, fructu præcoci ſubrotundo albido ſtriato, intus roſeo. Tourn.* The roundiſh white-ſtriped Fig.
9. Ficus *ſativa, fructu viridi, longo pediculo inſidente. Tourn.* The green Fig.
10. Ficus *ſativa, fructu parvo ſerotino albido, intus roſeo, mellifluo, cute lacera. Tourn.* The *Marſeilles* Fig.
11. Ficus *ſativa, fructu flaveſcente, intus ſuave rubente. Tourn.* The Yellow Fig.
12. Ficus *ſativa, fructu majori violaceo oblongo, cute lacera. Tourn.* Great long Violet Fig.
13. Ficus *ſativa, fructu magno rotundo depreſſo ſpadiceo, circa umbilicum dehiſcente, intus ſuave rubente. Garid.* The Roſe Fig.
14. Ficus *ſativa, fructu magno rotundo albo mellifluo, foliis magis diſſectis.* The great White Turkey Fig, with deeply-cut Leaves.
15. Ficus *ſativa, fructu longo majori nigro, intus albo ſerotino. Tourn.* The great Black Fig, with a white Pulp.
16. Ficus *ſylveſtris Cretica, folio non diviſo, leviter crenato. T. Cor.* The Candia wild Fig, with undivided Leaves, *falſly call'd the* Sycamore-tree.
17. Ficus *Americana, latiori folio venoſo, ex Curacao. Pluk. Alm.* The Broad-leav'd *American* Fig.
18. Ficus *Malabarenſis, folio cuſpidato, fructu rotundo parvo gemino. D. Syen. Pluk. Alm.* The *Malabar* Fig, or *Indian* God Tree.

The firſt fifteen Sorts are cultivated in curious Gardens for their Fruits, which are eſteem'd, by all delicate Palates, amongſt the richeſt Sorts of Fruits; tho' few vulgar Taſtes care for 'em, ſo that they are often planted in Places expos'd, where few other Fruits would eſcape being ſtolen. In *England* we have but few Sorts of this Fruit, compar'd with the vaſt Varieties with which the Southern Parts of *France* and *Italy* abound: Tho' it is to be hop'd that in a few Years we ſhall be ſupply'd with moſt of their curious Sorts; eſpecially ſince we ſee yearly, that great Numbers of People come to reliſh them. But one great Diſcouragement to the Propagation of theſe Trees, was the Unſkilfulneſs of the *Engliſh* Gardeners in their Culture and Management. I ſhall therefore begin with an Account of the Planting, Increaſing, and Pruning of theſe Trees; which I ſhall treat as clear as poſſibly I can, and only mention the Methods uſed, with which I have had great Succeſs.

The common Method of propagating theſe Trees is from Suckers which come up from the Roots of old Trees. But this is what I would never adviſe; for theſe Plants, when grown large, are much more ſubject to produce Suckers again, than thoſe raiſed by Layers, which are by far the beſt rooted and moſt promiſing Plants: Therefore I would always make choice of the latter Method, eſpecially ſince they are very eaſy to be propagated that way; for if you lay down the Branches in *February*, they will be fit to remove by the ſucceeding *February*, which is the beſt Time to tranſplant them; becauſe thoſe planted in Autumn are very apt to be deſtroy'd, eſpecially if the Winter ſhould prove hard, or the Soil be moiſt into which they are planted.

The beſt Soil for *Figs* in *England*, is ſuch as hath a gravelly, chalky, or ſtony Bottom, with a light dry Surface: for altho' a ſtrong Soil will produce vigorous Branches and large Leaves; yet the Fruit will not be in ſuch Plenty, nor ſo well taſted, as thoſe which grow on a poor and dry Soil.

Fig-trees ſhould always be planted in a free open Situation, not under the Drip of Trees, nor ſhaded by Buildings, *&c.* But there are very few Sorts that will ripen well with us in *England*, moſt of them requiring a good South, South-Eaſt, or South-Weſt Wall: for although they will grow very well againſt a North or Eaſt-aſpected Wall; yet the Fruit will be very poor, (if any are produc'd) ill-taſted, and late ripe.

Thoſe Trees which are planted for Standards in the open Air will require very little Culture or Management: The chief Thing to be obſerv'd, is, to cut out all dead or decaying Branches, as alſo all ſuch as croſs each other, that the Middle of the Tree may not be too much crowded with Branches. The beſt Seaſon for this Work is in *October*, when the Leaves begin to decay; at which time you ſhould alſo diveſt the Branches of all the latter Crop of *Figs*, which, by being ſuffer'd to remain upon the Tree, will, with the firſt Froſt, rot and decay, and thereby infect the tender Branches: For by ſeveral Experiments made by the Reverend and Learned Dr. *Hales* and myſelf, we found that all thoſe Branches which were diveſted of the *Figs* at that Seaſon, remain'd perfectly ſound, and produc'd Fruit in plenty the ſucceeding Year; whereas the other Branches of the ſame Tree whereon the Fruit were left, were almoſt totally deſtroy'd in the Winter. The Reaſon for my making choice of this Seaſon, is becauſe at that Time they are not ſo ſubject to bleed; and the Wounds then made, if cut cloſe and ſmooth, will heal over in a ſhort Time: but it muſt be done early in the Autumn, before the froſty Weather comes on, which would be very apt to enter the Places where ſuch Wounds were made, and prove very hurtful to the Tree.

But I ſhall next treat of the Management neceſſary for *Wall Fig-trees*, which is, perhaps, as little underſtood as any Part of Gardening, not only in *England*, but alſo in *France*, *Holland*, and moſt other Countries. In *France*, great Numbers of theſe Trees are planted in Tubs or Caſes, and are every Winter preſerv'd in Green-houſes, with Oranges, Myrtles, *&c.* This indeed may be a very good Method to obtain early *Figs*, provided they are rightly manag'd; which, I think, can hardly be done, if intermix'd with other Kinds of Trees, whereby their Branches are apt to mould and ſuffer, for want of a ſufficient Quantity of free Air, which theſe Trees ſhould always have in open mild Weather. Beſides, the Fruit will be apt to come out very early in the Spring, eſpecially if the Houſe is kept warm, whereby they will be liable to many Accidents when they are expoſed to the open Air. So that, upon the whole, I would never adviſe this Practice in *England*, unleſs in ſuch Places where they have an open airy Glaſs-caſe, in which there are no other Sorts of Plants.

Therefore the ſureſt Method is, to plant 'em againſt warm Walls, and upon a dry warm Soil. The Diſtance theſe Trees ſhould be planted ought never to be leſs than twenty Feet, ſuppoſing the Wall to be fourteen or more Feet in Height; for when they are planted too near, the Branches are train'd upright, and thereby cover the Walls in a few Years with old Wood, ſo that there are no younger Branches to produce Fruit but what are ſituated at the extreme Parts of the Tree, or ſtand forward from the Wall, which is a very great Fault, as ſhall be hereafter demonſtrated. In the Middle, between the *Fig-trees*, may be planted a Vine, which may be preſerv'd to bear Fruit until the *Fig-trees* do cover the Wall; at which Time they ſhould be intirely taken away; for they ſhould by no means be ſuffer'd to intermix their Shoots amongſt the *Figs*, which would prevent the Ingreſs of the Air, which is abſolutely neceſſary to give the Fruit a fine racy Flavour.

In the Summer, when the *Fig-trees* begin to ſhoot, you ſhould train the Branches horizontally to the Walls, (as is directed for other Fruit-trees) for if they are ſuffer'd to grow all the Summer without Management, their Shoots will be too ſtubborn to be drawn regularly to the Wall: Nor ſhould you ſuffer any foreright Shoots to be produc'd upon your young Trees; but, on the contrary, as faſt as they appear, you ſhould rub off their Buds. At *Michaelmas*, (as I ſaid before) is the beſt Seaſon for pruning and nailing theſe Trees, not only for the Reaſons before aſſign'd, but alſo becauſe their Shoots being nail'd cloſe to the Wall before the ſevere Froſts come on, will be leſs liable to be injur'd thereby.

The main Things to be obſerv'd in the pruning of older Trees, are, 1ſt, Always to take care to have a Supply of young Branches in every Part of the Tree, for it is thoſe only which produce Fruit: 2dly, Never to ſhorten any of the Shoots at the Autumn Pruning, which would intirely deprive you of Fruit, ſince it is chiefly upon the Wood of the laſt two Years that it is produc'd: 3dly, Always obſerve to nail your young Fruit-branches cloſe to the Wall, whereby they will not be deſtroy'd by Froſt, and the Fruit will be forwarded at leaſt a Fortnight or three Weeks in the Spring, which is of great Conſequence to us in *England*: 4thly, Never lay in your old Branches too thick, which is a very common Fault amongſt Gardeners; for as the Shoots are vigorous, and the Leaves of theſe Trees very large, ſo their Diſtance ought never to be leſs than ten or twelve Inches: So that as young Branches increaſe, the old ones ſhould be intirely cut out; which may be done in the Autumn with as much Safety as to any other Tree: 5thly, In order to produce young Branches, you may ſtop the leading Bud of young vigorous Shoots in *April*, or the Beginning of *May*, which will occaſion the Side-buds to break out into lateral Branches, whereby the Wall may be kept conſtantly furniſh'd with young Wood; but I would by no means adviſe the doing of this too often, nor ſhould it be done later in the Year; for multiplying Branches too much, is of as bad Conſequence as having too few, for it will occaſion their being weak and unfruitful; and if it is done in *June* or *July*, it will only occaſion the Buds to produce *Figs* in great Plenty, which will never come to good ſo late in the Year, and will greatly weaken the tender Fruit-branches, and prevent their bearing the next Spring.

If the Winter ſhould prove extreme ſharp, it will be neceſſary to cover your choiceſt Sorts of *Fig-trees*, either with Straw, Reeds, Peaſe Haulm, or ſome other ſuch like Covering, which will preſerve the tender Fruit-branches from being injur'd; for want of which Care, in the Winter *Anno* 1728, the *Fig-trees* ſuffer'd very much in moſt Parts of *England*: By this Method your Fruit will be greatly forwarded, but you ſhould be very careful not to remove your Covering too early in the Spring, nor to do it all at once, but open them firſt in the Day-time, and cover them again at Night, and ſo by Degrees inure them to the open Air. In ſome Places where this Method has been carefully obſerv'd, I have ſeen ripe *Figs* almoſt a Month ſooner than where they were not cover'd, and the Fruit in much greater Plenty.

Theſe Trees do very well againſt the warm Side of a Houſe, or other large Building, where they have a great Compaſs of Walling; and the higher theſe Trees are train'd from the Ground, the better the Fruit is taſted, eſpecially, if it b againſt a Chimney, where it may enjoy ſome Share of Warmt thro' the Bricks: And *Figs*, tho' the moſt delicate of Fruits being very little eſteem'd by vulgar Palates, are leſs liable to b ſtolen by Servants or common People than ſome of the mor common Sorts of Fruits.

I am aware, that what I have here advanc'd, in relation t the pruning and dreſſing of *Fig-trees*, will be condemn'd b great Numbers of People, who will not give themſelves Tim to conſider and examine the Reaſons upon which I have founded this Practice, nor to make one ſingle Experiment to try t Truth of it, as being vaſtly different from the general Practic of moſt Gardeners, who always imagine, that *Fig-trees* ſhou never have much pruning, or at leaſt, that they ſhould alwa be ſuffer'd to grow from the Wall to ſome Diſtance: That b this Management, I have often ſeen great Quantities of Frui I cannot deny, but then this has been only in mild Winter for it is very certain, that in ſharp Froſts few of theſe outſi Shoots eſcape being greatly injured; whereas it rarely happe that thoſe Shoots which are cloſely nail'd to the Wall at *M*

chaelm

chaelmas, do ſuffer the leaſt Damage, and the Fruits are always produc'd a Fortnight ſooner upon theſe Branches than they are upon thoſe which grow from the Wall.

The Seaſon alſo for pruning, which I have laid down, being vaſtly different from the common Practice and Opinion of moſt Gardeners, will alſo be objected againſt; but this I am ſure, if any one will but make Trial of it, I doubt not but his Experience will confirm what I have here advanc'd; for as one great Injury to this Tree proceeds from the too great Effuſion of Sap at the wounded Parts, ſo by this Autumn-pruning this is prevented; for at that Seaſon, all the Parts of *European* Trees which caſt their Leaves, are leſs replete with Moiſture than at any other Time of the Year; for by the long Continuance of the Summer's Heat, the Juices of Plants having been exhauſted in the Nouriſhment and Augmentation of Wood, Leaves, Fruits, *&c.* and alſo great Quantities being evaporated by Perſpiration, the Root not being able to ſend up a Supply equivalent to this great Conſumption, the Branches muſt contain a much leſs Quantity of Sap than in the Spring, when it has had ſeveral Months Supply from the Root, which tho' but ſmall in proportion to what is ſent up when the Heat is greater, yet there being little or no Waſte, either by Perſpiration or Augmentation, there muſt be a greater Quantity contain'd in the Branches; which alſo is eaſily to be obſerv'd, by breaking or cutting off a vigorous Branch of a *Fig-tree* at both Seaſons (the Sap being milky may be readily diſcern'd) when that cut in Autumn ſhall be found to ſtop its bleeding in one Day's Time, or leſs; whereas that cut in the Spring will often flow a Week or more, and the Wound will be proportionably longer before it heals.

Tho' the Liſt of *Figs*, which I have here added, may be greater in Number of Sorts than many People at preſent know, yet it is very ſmall when compared with the great Variety of Sorts which are known in the more Southern Countries of *Europe*; from whence I am in Hopes, in a ſhort Time, I ſhall be ſupply'd with many more Kinds than are here mentioned: Nor do I think there is any Sort of Fruit deſerves more our Care to cultivate and improve than this; and yet it rarely happens that we meet with more than four or five Sorts in moſt of our curious Fruit-Gardens, when at the ſame time, perhaps, the Walls are fill'd with great Collections of *Pears* and *Plums*, few of which either deſerve the Place or Care taken in their pruning, *&c.* or at leaſt would thrive as well if planted in Eſpaliers or Standards.

Fig-trees do very well in Eſpaliers, eſpecially the ſmall White, the early Blue, and the *Brunſwick Figs*; but theſe are liable to Injury from ſharp Froſts in Winter, being more expoſed than thoſe planted againſt Walls: However, if we ſhould be at the Expence of covering them in hard Winters, there is no doubt but they would ſucceed very well.

The ſixteenth Sort is by many People ſuppoſed to be the true *Sycamore-tree* mention'd in Scripture, which is a Sort of *Fig* which produces its Fruit out of the old Wood of the Tree, and is very ſmall; but as this Tree has not produced any Fruit with us, ſo I cannot determine whether it be the right Kind, or not.

It may not be improper in this Place to mention the great Pains which the Inhabitants of the *Levant* are at in the Culture of their *Figs*; and without which (it is generally ſaid by all the Travellers who have wrote on this Subject, as alſo by *Pliny*, and other old Naturaliſts) that their Fruit would fall off, and be good for nothing. I ſhall here ſet it down, as I find it in the *Travels* of Monſieur *Tournefort*, chief Botaniſt to the late King of *France*.

“ *Pliny* (ſays he) obſerv'd, that in *Zia* they uſed to dreſs their *Fig-trees* with much Care; they ſtill continue to do ſo. To underſtand aright this Huſbandry of *Figs*, (call'd in Latin *Caprificatio*) we are to obſerve, that in moſt of the Iſlands of the *Archipelago*, they have two Sorts of *Fig-trees* to manage: The firſt is call'd *Ornos*, from the old Greek *Erinos*, a wild *Fig-tree*: or *Caprificus* in Latin; the ſecond is the Domeſtick or Garden *Fig-tree*: The wild Sort bears three Kinds of Fruit, *Fornites*, *Cratitires*, and *Orni*, of abſolute Neceſſity towards ripening thoſe of the Garden *Fig*.

“ The *Fornites* appear in *Auguſt*, and continue to *November* without ripening; in theſe breed ſmall Worms, which turn to a Sort of Gnats, no where to be ſeen but about theſe Trees: In *October* and *November* theſe Gnats of themſelves make a Puncture into the ſecond Fruit, which is call'd *Cratitires*, and don't ſhew themſelves till towards the End of *September*; and the *Fornites* gradually fall away after the Gnats are gone: The *Cratitires*, on the contrary, remain on the Tree till *May*, and incloſe the Eggs depoſited by the *Fornites* when they prick'd them. In *May* the third Sort of Fruit begins to put forth from the ſame wild *Fig-trees* which produced the other two; this is much bigger, and is call'd *Orni*: When it grows to a certain Size, and its Bud begins to open, it is prick'd in that Part by the Gnats of the *Cratitires*, which are ſtrong enough to go from one Fruit to the other to diſcharge their Eggs.

“ It ſometimes happens, that the Gnats of the *Cratitires* are ſlow to come forth in certain Parts, while the *Orni* in thoſe very Parts are diſpos'd to receive them: In which Caſe the Huſbandman is obliged to look for the *Cratitires* in another Part, and fix them at the End of the Branches of thoſe *Fig-trees*, whoſe *Orni* are in fit Diſpoſition to be prick'd by the Gnats: If they miſs the Opportunity, the *Orni* falls, and the Gnats of the *Cratitires* fly away. None but thoſe who are well acquainted with this Sort of Culture, know the critical Minutes of doing this; and in order to it, their Eye is perpetually fix'd on the Bud of the *Fig*; for that Part not only indicates the Time that the Prickers are to iſſue forth, but alſo when the *Fig* is to be ſucceſsfully prick'd: If the Bud be too hard, and too compact, the Gnat can't lay its Eggs, and the *Fig* drops when this Bud is too open.

“ Theſe three Sorts of Fruit are not good to eat; their Office is to help ripen the Fruit of the Garden *Fig-trees*, in manner following: During the Months of *June* and *July*, the Peaſants take the *Orni* at a Time that their Gnats are ready to break out, and carry them to the Garden *Fig-trees*: If they don't nick the Moment, the *Orni* falls, and the Fruit of the Domeſtick or Garden *Fig-tree* not ripening, will, in a very little Time, fall in like manner. The Peaſants are ſo well acquainted with theſe precious Moments, that every Morning, in making their Inſpection, they only transfer to their Garden *Fig-trees* ſuch *Orni* as are well-condition'd, otherwiſe they loſe their Crop. 'Tis true, they have one Remedy, tho' an indifferent one; which is, to ſtrew over the Garden *Fig-trees* the *Aſcolimbro's*, a very common Plant there, and in whoſe Fruit there are a Sort of Gnats proper for pricking: Perhaps they are the Gnats of the *Orni*, which are us'd to hover about and plunder the Flowers of this Plant.

“ To ſum up all in a Word: The Peaſants ſo well order the *Orni*, that their Gnats cauſe the Fruit of the Garden *Fig-tree* to ripen in the Compaſs of forty Days. Theſe *Figs* are very good green: When they would dry 'em, they lay 'em in the Sun for ſome Time, then put 'em into an Oven to keep 'em the reſt of the Year. Barley-bread and dry'd Figs are the principal Subſiſtence of the Boors and Monks of the *Archipelago*. But theſe *Figs* are very far from being ſo good as thoſe dry'd in *Provence*, *Italy*, and *Spain*; the Heat of the Oven deſtroys all their Delicacy and good Taſte: But then, on the other hand, this Heat kills the Eggs which the Prickers of the *Orni* diſcharged therein; which Eggs would infallibly produce ſmall Worms that would prejudice theſe Fruits.

“ What an Expence of Time and Pains is here for a *Fig*, and that but an indifferent one at laſt! I could not ſufficiently admire the Patience of the *Greeks*, buſied above two Months in carrying theſe Prickers from one Tree to another. I was ſoon told the Reaſon; One of their *Fig-trees* uſually produces between two and three hundred Pounds of *Figs*, and ours in *Provence* ſeldom above twenty-five.

“ The Prickers contribute, perhaps, to the Maturity of the Fruit of the Garden *Fig-tree*, by cauſing to extravaſate the nutritious Juice, whoſe Veſſels they tear aſunder in depoſiting their Eggs: Perhaps too, beſides their Eggs, they leave behind them ſome Sort of Liquor proper to ferment gently with the Milk of the *Fig*, and to make their Fleſh tender. Our *Figs* in *Provence*, and even at *Paris*, ripen much ſooner for having their Buds prick'd with a Straw dipt in Olive-oil. *Plums* and *Pears* prick'd by ſome Inſect, do likewiſe ripen much the faſter for it; and the Fleſh round ſuch Puncture is better-taſted than the reſt. It is not to be diſputed but that conſiderable Change happens to the Contexture of Fruits ſo prick'd; juſt the ſame as to the Parts of Animals pierc'd with any ſharp Inſtrument.

“ 'Tis ſcarce poſſible well to underſtand the ancient Authors who have treated of Caprification, (or huſbanding and dreſſing the wild *Fig-tree*) if one is not well appriz'd of the Circumſtances; the Particulars whereof were confirmed to us not only at *Zia*, *Tinos*, *Micone*, and *Scio*, but in moſt of the other Iſlands.”

The ſeventeenth and eighteenth Sorts here mentioned are very tender Plants, being Inhabitants of very warm Countries: I receiv'd Seeds of both theſe Sorts from *Jamaica*, from which I rais'd many Plants, ſome of which are grown to a conſiderable Size; and the ſeventeenth Sort has puſh'd out many ſmall *Figs* from the Joints, but they dropt off in a ſhort Time without coming to Maturity.

The eighteenth Sort is call'd the *Indian God-tree*, it being a Tree under which the religious *Indians* perform their Worſhip.

Theſe are both very handſome Plants, and deſerve a Place in all curious Collections of Exotick Trees: They may be propagated by Layers, as the common *Fig*, but ſhould be planted in Pots of freſh Earth, and preſerv'd in Stoves: In the Summer they may be expos'd during the Months of *July* and *Auguſt*, but muſt be removed into Shelter early in *September*. During the Winter-ſeaſon they will require frequent Waterings, provided the Stove is kept to a good Degree of Heat, otherwiſe they muſt be watered very ſparingly. The Temper of Heat which theſe Plants do beſt agree with in the Winter, is about the temperate Point, as mark'd on Mr. *Fowler's Botanical Thermometers*; for in a much greater Degree of Heat they will grow too freely in Winter; and in a leſs, they will be apt to drop their Leaves, and loſe their leading Bud, whereby the Beauty of the Tree will be greatly impaired. But if you are deſirous to have theſe Trees grow to a large Size, and in a ſhort Time, you ſhould plunge their Pots into Tanners Bark, which will cauſe them to make a conſiderable Progreſs. I have had Plants of the ſeventeenth Sort, which, by this Management, have been eight Feet high in two Years from the Time of ſowing the Seeds, and the Leaves have been prodigiouſly large and fair.

FICUS INDICA. *Vide* Opuntia.

FILACEOUS ROOTS; ſuch as are full of Filaments, *i. e.* of ſmall Threads or Strings.

FILAGO. *Vide* Gnaphalium.

FILBERT. *Vide* Corylus.

FILIPENDULA, [of *Filum*, a *Thread*, and *pendere*, Lat. to *hang*; ſo called of pendent Threads of the Roots, having little Nodes at the Ends] Dropwort.

The *Characters* are;

It hath a fibroſe Root, with oblong Bulbs or Tubers faſtened to the Bottom of the Fibres: The Leaves are finely cut into narrow Segments: The Flowers, which conſiſt of ſix or ſeven Petals, are diſpoſed into a looſe Panicle: The Fruit is almoſt round, containing many Seeds, which are gather'd into a Head reſembling a Tub.

The *Species* are;

1. FILIPENDULA *vulgaris, An, Molon Plinii. C. B.* Common Dropwort.
2. FILIPENDULA *vulgaris, An, Molon Plinii folio variegato. H. R. Par.* Common Dropwort, with a variegated Leaf.
3. FILIPENDULA *omni parte major, folio anguſtiori. Boerh. Ind.* Larger Dropwort, with a narrower Leaf.

The firſt of theſe Species is uſed in Medicine, but is ſeldom cultivated in Gardens: It grows wild in moſt Parts of *England* upon open Heaths and Commons, as alſo upon chalky Hills.

The ſecond Sort is a Variety of the firſt, with ſtriped Leaves, and is preſerved in ſome curious Gardens by ſuch as delight in variegated Plants.

The third Sort I brought from *Holland*, *Anno* 1727. This differs from the common Sort in being larger in every Part; but the Leaves are narrower, and finer cut.

Theſe Plants may be eaſily propagated by taking up their Roots in Autumn when the Leaves begin to decay, and parting them into ſmall Heads; which, if planted in an open Situation, will thrive and increaſe exceedingly. They may alſo be propagated by ſowing their Seeds in Autumn, which will come up the ſucceeding Spring, and the ſecond Seaſon will flower: But this is not the ſureſt Way to preſerve the Kinds; for they may be apt to vary from the Sorts ſown.

FILIUS ANTE PATREM, [i. e. *the Son before the Father*] an Expreſſion which *Botaniſts* apply to Plants whoſe Flower comes out before their Leaves.

FILIX, Fern. There are great Varieties of this Plant in the different Parts of the World, but particularly in *America*, as may be ſeen in the *Natural Hiſtory of Jamaica*, publiſhed by Sir *Hans Sloane*, Bart. and in *Plumier's American Ferns*: But as they are Plants which are ſeldom propagated in Gardens, I ſhall paſs them over in this Place.

FILM; that woody Skin which ſeparates the Seeds in the Pods of Plants.

FIMBRIATED; [of *Fimbria*, Lat. a *Fringe*] a Term relating to the Leaves of Plants when they are jagged on the Edges, having, as it were, a Fringe about them.

FIRE. However foreign, at the firſt View, this Article may ſeem to our preſent Purpoſe, yet I am of Opinion, that a tolerable Acquaintance with its Nature, as far as it can be attain'd, and its Effects, will contribute no ſmall Aſſiſtance in forwarding the Work of Vegetation. And tho' the Theory of *Fire* is indeed Philoſophical; yet the Conſideration of its Effects, and how it operates on Vegetables, will be of no ſmall Uſe in the Culture of them.

That which beſt defines and diſtinguiſhes *Fire* from every Thing elſe, is its Heating; and ſo it may be defined, whatſoever warms or heats Bodies.

Heat is ſomething, the Preſence of which is beſt perceiv'd by the Dilatation of the Air or Spirit in the Thermometer. So then, *Fire* is a Body, and a Body in Motion too. The Motion of it is prov'd by its expanding the Air, and that it is a Body, by Experiment.

Pure *Mercury* being incloſed in a Phial with a long Neck, and kept in a gentle Heat for the Space of a Year, will be reduced into a Solid, and the Weight alſo will be increaſed conſiderably; which Increaſe cannot proceed from any Thing elſe but the Acceſſion of *Fire*.

The Nature of *Fire* is ſo obſcure and wonderful, that it was held, by many of the Antients, as a Deity; and ſeveral Authors of prime Note have taken great Pains to diſcover the Myſtery of it, without having been able to explain many of the principal Effects thereof. The learned *Herman Boerhaave* has uſed no leſs Induſtry in making a new Set of Experiments in order to come to a clearer Knowledge of them; and having laid down a new Doctrine of *Fire*, in a Courſe of Publick Lectures, I ſhall briefly take notice of ſuch of them as I apprehend may be of Uſe.

" *Fire*, (ſays he) in effect, appears to be the general Inſtrument of all the Motion in the Univerſe: The conſtant Tenor of a great Number of Experiments leaves no Room to doubt, but that if there were no *Fire*, all Things would inſtantly become fix'd and immoveable. Of this there are Inſtances every Winter: For while Froſt prevails, the Water, which before was fluid, by a mere Privation of Heat, becomes ſolid, *i. e.* hardens into Ice, and ſo remains, 'till reſolv'd again by *Fire*. Thus, were a Man intirely deſtitute of Heat, he would immediately freeze into a Statue. And thus the Air itſelf, which is found in continual Motion, being always either expanding, or condenſing, would, upon the Abſence of *Fire*, contract itſelf, and cohere into a firm, rigid Maſs. So alſo Animals and Vegetables, all Oils, Salts, *&c.* would, upon the like Occaſion, immediately congeal."

Altho' this Doctrine of *Fire*, here laid down by *Boerhaave*, ſeems new and extraordinary, at leaſt to thoſe who have been us'd to conſider *Fire* in the Light that it has been ſet in by the Lord *Bacon*, Mr. *Boyle*, and Sir *Iſaac Newton*; and tho' we ought to pay great Veneration to thoſe illuſtrious Authors; yet, in the Judgment of themſelves, we ſhould be inexcuſable, if we ſhould abſolutely acquieſce in what they have done, and ſhut the Door againſt farther and better Information.

It may reaſonably be ſuppos'd that Dr. *Boerhaave* has had an Opportunity of going beyond them; in that, beſides all the Experiments and Obſervations that they have had to build upon, he has had the Advantage of a new Set, which they were unacquainted with.

As to the Nature of *Fire*, the great and fundamental Difference is, Whether it be originally ſuch, form'd thus by the Great Creator Himſelf, at the Beginning of Things? or, Whether it be mechanically producible from other Bodies, by inducing ſome Alteration in the Particles of it?

Among the modern Writers, *Homberg*, *Boerhaave*, the Younger *Lemery*, and Dr. *Graveſande* maintain the former, and the *Engliſh* Authors chiefly maintain the latter.

Monſ. *Homberg* holds, That the Chymical Principle or Element *Sulphur*, which is ſuppos'd one of the Simple, Primary, Pre-exiſtent Ingredients of all Natural Bodies, is Real *Fire*; and of Conſequence, *Fire* is coeval with all Bodies. *Eſſai du Souffre Principe*, Mem. de l'Acad. Anno 1705.

Dr. *Graveſande* proceeds much on the ſame Principle: According to him, *Fire* enters the Compoſition of all Bodies, is contain'd in all Bodies, and may be ſeparated or procured from all Bodies, by rubbing them againſt each other, and thus putting their *Fire* in Motion. And he adds, That *Fire* is by no means generated by ſuch Motion. *Elem. Phyſ. tom.* 2. *cap.* 1.

Mr. *Lemery* the Younger aſſerts the abſolute and ingenerable Nature of *Fire*; and alſo extends it farther. Not contented to confine it, as an Element, to Bodies, he endeavours to ſhew, that it is "Equably diffus'd thro' all Space; is preſent in all Places; in the void Space between Bodies, as well as the inſenſible Interſtices between their Parts." *Mem. de l'Acad.* Anno 1713.

This laſt Sentiment falls in with that of *Boerhaave*.

Of the contrary Opinion is the Lord *Bacon*, who, in his Treatiſe *de Forma Calidi*, deduces from a great Number of Particulars, That *Heat* in Bodies is no other than *Motion*; only a Motion ſo and ſo circumſtantiated; ſo that, to produce *Heat* in a Body, nothing is requir'd but to excite ſuch Motion in the Parts of it.

His Opinion is ſeconded by Mr. *Boyle*, in his Treatiſe of the *Mechanical Origin of Heat and Cold*, where he maintains the ſame Doctrine, with new Obſervations and Experiments; of which, two are as follow:

He ſays, "In the Production of *Heat*, there appears nothing on the Part either of the Agent or Patient but Motion, and its natural Effects. When a Smith briſkly hammers a ſmall Piece of Iron, the Metal thereby becomes exceedingly hot; yet there is nothing to make it ſo, except the forcible Motion of the Hammer, impreſſing a vehement and variouſly-determin'd Agitation on the ſmall Parts of the Iron; which being a cold Body before, becomes, by that ſuper-induc'd Commotion of its ſmall Parts, *Hot*: firſt, in a more looſe Acceptation of the Word, with regard to ſome other Bodies, compar'd with which, it was Cold before: then, ſenſibly Hot; becauſe this Agitation ſenſibly ſurpaſſes that of the Parts of our Fingers. And in this Inſtance, oftentimes the Hammer and Anvil continue cold after the Operation, Which ſhews, that the Heat acquir'd by the Iron was not communicated by either of theſe Implements, as Heat, but produc'd in it by a Motion great enough ſtrongly to agitate the Parts of ſo ſmall a Body as the Piece of Iron, without being able to have the like Effect upon ſo much greater Maſſes of Metal as the Hammer and Anvil: Tho' if the Percuſſions were often and briſkly renew'd, and the Hammer were ſmall, this alſo might be heated: Whence it is not neceſſary that a Body itſelf ſhould be hot, to give Heat.

"If a large Nail be driven by a Hammer into a Plank of Wood, it will receive ſeveral Strokes on its Head e're it grows hot: but when it is once driven to the Head, a few Strokes ſuffice to give it a conſiderable Heat. For while at every Blow with the Hammer the Nail enters farther into the Wood, the Motion produc'd is chiefly progreſſive, and is of the whole Nail tending one Way: but when the Motion ceaſes, the Impulſe given by the Stroke being unable to drive the Nail farther on, or break it, muſt be ſpent in making a various, vehement, and inteſtine Commotion of the Parts among themſelves, wherein the Nature of Heat conſiſts." See *Heat*.

That *Fire* is the real Cauſe of all the Changes in Nature, will appear from the following Conſideration.

All Bodies are either *ſolid* or *fluid*; the *ſolid* of themſelves are either commonly ſuppos'd to be unactive or motionleſs; the *fluid* both move, and are moved.

And all Solids are found to be ſo much the more firm and contracted, as they have the leſs *Fire* in them: This is evident in Iron, which, when heated, expands itſelf into a much greater Space than when it was cold; ſo that any ſolid and hard Body, by being freed from all *Fire*, would ſink into a much leſs Bulk, and its Parts would cohere more nearly, and with greater Force than before.

As to *Fluids*, they all harden, ſo as to be viſible to the Eye upon the Abſence of Fire: as Water, by the Cold of a ſevere Winter, will form itſelf into a ſolid Globe, and yet even then contains a great deal of *Fire*; as appears evidently upon applying a Thermometer to it, which is capable of falling twenty Diviſions lower before it arrive at the Point of the moſt intenſe Cold: And hence it is that the Spirit of Wine is kept from freezing in the Thermometer, which would undergo the common Fate of other Things, were there not abundantly more *Fire* in it.

So the Air itſelf expands by a greater Quantity of *Fire*, and condenſes by a leſs; but it ſtill contains a large Quantity of *Fire* where it is moſt of all contracted: This is evident from the ſtriking of a Flint againſt a Steel, which is follow'd by Sparks of *Fire*.

Likewiſe, if this *Fire* could be taken from the *Air*, it would become ſolid and perfectly at reſt, and by Conſequence uncapable of Change.

"*Fire* (ſays Dr. *Graveſande*, in *Element. Phyſ.*) naturally unites itſelf with Bodies: And hence it is that a Body brought near to the Fire grows *Hot*; in which Caſe it alſo expands or ſwells; which Expanſion is not only obſerv'd in very ſolid Bodies, but in thoſe whoſe Parts do not cohere; which Caſe they likewiſe acquire a great Degree of Elaſticity, as is obſerved in Air and Vapours."

Fire being thus acknowledg'd the Inſtrumental Cauſe of all Motion; it remains, that itſelf be moved. Nay, to move, muſt be more natural and immediate to *Fire* than to any other Body; and hence ſome have ventur'd to make *Motion* eſſential to *Fire*. But as this is inconſiſtent with the Notion of Matter, which is defin'd to be inert and paſſive, and as *Fire* is capable of being prov'd material; we ought rather to agree, that the Motion of *Fire* itſelf is derived from ſome higher and metaphyſical Cauſe. A Property of perpetual Mobility may indeed be ſuperadded to the other Properties of *Fire*: but it has no natural neceſſary Connection with them; nor can it be maintain'd with them otherwiſe than by ſome extrinſick Efficacy of a ſuperior Cauſe.

However, that it is by *Motion* that *Fire* produces its Effects, is evident: And hence the Action of *Fire* cannot make any Alteration in the elementary Subſtance of Bodies: For it is neceſſary that what acts upon an Object, be without that Object; *i. e.* the *Fire* muſt not penetrate the elementary Parts, but only enter the Pores and Interſtices of Bodies: ſo that it does not ſeem capable of making thoſe Tranſmutations which Sir *Iſaac Newton* aſcribes to it.

In effect, as to all our Purpoſes, it may perhaps be ſaid, that *Fire* is always in Motion. For Inſtance: Take ſix ſeveral Sorts of Thermometers, and two Veſſels of Water with *Sal Armoniac* mix'd therein, and apply the Thermometers to it; and the Conſequence will be, that the Air being condenſed in them, the Spirit will deſcend in all of 'em: Remove the Veſſels of Water, and the Air growing warmer, and ſo rarefying, the Spirit will aſcend again. So that the active Force in Air which produces ſo many Effects, does really all ariſe from the *Fire* contain'd in it.

Again: As all Bodies plac'd in a very ſolid Air, do by Degrees grow cold, motionleſs, rigid, &c. *i. e.* tho' there be ſtill ſome Remains of *Fire*; and in Proportion, as that is diminiſh'd, the Effect is accelerated: It follows, that *Cold*, a leſs Degree of *Heat*, is the Effect of a leſſer Action of *Fire*. And ſo, all Action ariſes apparently from the ſame Source.

Then as *Fire* can render the moſt ſolid Bodies, as Stone, Metals, &c. fluid, (as appears very evident in large Burning-Glaſſes, in which Gold itſelf immediately calcines, and emits Fumes, *i. e.* becomes fluid) ſo the Want of *Fire* would convert the moſt fluid Bodies, as Spirits of Wine, &c. into Solids.

Fire is diſtinguiſh'd into two Kinds, call'd *elementary* or *pure Fire*, which is ſuch as exiſts in itſelf, and alone is properly call'd *Fire*; or *common* or *culinary Fire*, which is raiſed and kindled from the former, and is that which agitates and affects ignited, combuſtible, and moveable Bodies, the Particles of which joining with thoſe of the pure *Fire*, conſtitute pure *Flame*.

This latter is improperly call'd *Fire*, in that only a ſmall Part of it is real or pure *Fire*; and in ignited Bodies, that which flames, ſmokes, &c. is not ſimply *Fire*; whereas pure *Fire*, ſuch as is collected in a Burning-Glaſs, yields no Flame, Smoke, Aſhes, or the like.

Fire may be preſent in the greateſt Abundance, yet without any Heat: This is evident in the Tops of the higheſt Mountains, illuminated by the Sun, where the Cold is always extremely pinching, and this even under the *Equator*, there being Mountains there which are perpetually cover'd with Snow, tho' there can be no Want of *Fire*.

So a large Burning-Glaſs has no Effect, the ſmalleſt Warmth cannot be felt in its *Focus*, in a Place where the Sun does not ſhine, or when the Sun is cover'd with a Cloud; but a Piece of Metal may be ſeen to melt the very Moment the Sun emerges.

Fire may be in exceeding ſmall Quantity, and yet burn with great Violence: Thus Spirit of Wine, when ſet on fire, does not burn the Hands, and tho' pour'd on a Piece of red-hot Iron, does not take Fire; ſo that the Fire that is in ſhould not appear very great, yet if it meet with ſome harder Body while it is burning, the Particles of which Body it is capable to agitate by the Attrition of its own, it will yield a fierce Flame capable of burning a harder Body than the Hand.

From this it appears, that the Relation of heterogeneous Particles agitated by the *Fire*, has more Effect in reſpect to Heat than the Action of the *Fire* itſelf: Nor need we be far to ſeek for the mechanical Reaſon of this; for the Particles of

Fire being all equal and ſpherical, muſt of themſelves be harmleſs; but if they carry certain *Spicula*, or any other Bodies along with them, they then become capable of doing much Harm.

Hence, tho' the Flame of a Piece of Wood may give a Senſe of Heat, and burn ſuch Things as are apply'd to it, it does not therefore neceſſarily follow, that there is any pure *Fire* in it, ſo that the Diſtinction of pure and common *Fire* is abſolutely neceſſary: Tho' this Diſtinction has been overlook'd by moſt or all the Authors before Dr. *Boerhaave*, who have written on *Fire*, which has led them into egregious Miſtakes, inſomuch, that moſt of them have held, that the Flame of a Piece of Wood is all *Fire*; which appears to be falſe from what has been already ſaid, and alſo what follows.

Elementary or *pure Fire* is of itſelf imperceptible, and only diſcovers itſelf by certain Effects that it produces in Bodies; and theſe Effects are only to be learnt by the Changes which ariſe in Bodies: Theſe Effects are three; 1ſt, *Heat*; 2dly, *Dilatation* in all ſolid Bodies, and *Rarefaction* in all Fluids; 3dly, *Motion*.

The firſt Effect of *elementary Fire* on Bodies is *Heat*: *Heat* ariſes wholly from *Fire*, and in ſuch a manner, that the Meaſure of Heat is always the Meaſure of *Fire*; and that of *Fire*, of *Heat*; ſo the *Heat* is inſeparable from the *Fire*.

The ſecond Effect of *elementary Fire* is *Dilatation* in all ſolid Bodies, and *Rarefaction* in all Fluids.

Numerous Experiments make it evident, that both theſe are inſeparable from *Heat*: If you heat an Iron Rod, it will increaſe in all its Dimenſions, and the more it is heated, the farther it will be increas'd; and being again expos'd to the Cold, it will contract, and ſucceſſively return thro' all Degrees of its Dilatation, till it arrives at its firſt Bulk, being never two Minutes ſucceſſively of the ſame Magnitude.

The like may be obſerv'd in Gold, the heavieſt of all Bodies, which takes up more Space when it is fuſed than it did before; nay, even Mercury, the heavieſt of all Fluids, has been known to aſcend to above thirty Times its Height, being plac'd over the Fire in a narrow Tube.

The Laws of this Expanſion are;

1ſt, That the ſame Degree of *Fire* rarefies Fluids ſooner and in a greater Degree than it does Solids. Without this, the Thermometer would be of no Uſe; ſince if it were otherwiſe, the Cavity of the Tube would be dilated in the ſame Proportion as the Fluid is rarefied.

2dly, By how much the Liquid is lighter, by ſo much the more it is dilated by *Fire*: Thus *Air*, which is the lighteſt of all Fluids, expands the moſt; and Spirit of Wine the next after Air.

The third Effect of *Fire* on Bodies is *Motion*: For *Fire*, in warming and dilating Bodies, muſt neceſſarily move their Parts. And in effect, all the Motion of Nature ariſes from *Fire* alone; and if this were taken away, all Things would become immoveable. All Oils, Fats, Waters, Wines, Ales, Spirits of Wine, Vegetables, Animals, *&c.* become hard, rigid, and inert upon the Abſence of only a certain Degree of *Fire*; and this Induration will be both the ſooner and the more violent, the leſs the Degree of *Fire* is.

Hence if the *Fire* was abſolutely taken away, and there were the greateſt Degree of Cold, all Nature would grow into one concrete Body, ſolid as Gold, and hard as a Diamond; but upon the Application of *Fire*, it would recover its former Mobility.

And of conſequence, every Diminution of *Fire* is attended with a proportionable Diminution of Motion.

Pure *Fire* is found in two different Manners, either as it exiſts every where, and is diffus'd equally in all Places; or as it exiſts in certain Bodies, in which it makes no great Alteration.

That *Fire* ſhould exiſt in the ſame Quantity in all Places, will ſeem a ſtrange Paradox, and yet that it does ſo, is demonſtrable from innumerable Experiments.

This *elementary Fire* is preſent every where, in all Bodies, all Space, and at all Times, and that in equal Quantities; for let a Perſon go where he will, to the Top of the higheſt Mountains, or deſcend into the loweſt Cavern, whether the Sun ſhine or not; either in the moſt ſcorching Summer, or the ſharpeſt Winter, *Fire* may be collected by ſeveral Methods, as Attrition, or otherwiſe. In a Word, there is no Phyſical Point aſſignable without *Fire*; no Place in Nature where the Attrition of two Sticks will not render it ſenſible.

The *Carteſians*, as *Marriotte*, *Perrault*, &c. hold, That there is a large Stock of *Fire* in a perfect *Vacuum*, *i. e.* a Space out of which all the Air has been exhauſted, as ſuppoſing an abſolute *Vacuum* impoſſible: Now the moſt perfect *Vacuum* that we can arrive at, is that of Mr. *Huygens*'s Contrivance, which is as follows: Heat a Quantity of the pureſt Mercury to the Heat of boiling Water, and pour it into a hot Tube of about forty Inches long; and when the Tube is fill'd, apply a Finger upon the Orifice of it, and thus invert it into a Baſon full of Mercury: The Mercury will now be ſuſpended in the Tube to the whole Height; but then if you give it but a little Shake, it will ſink down to the Height of about twenty-nine Inches, and thus leave a perfect Vacuity of eleven Inches.

Yet here the Philoſophers above-mention'd deny there is any *Vacuum*, and urge, that now ſo much the more *Fire* is enter'd into the Space as there was of other Matter: But this is contrary to Experience, at leaſt, the *Fire* contain'd there is no hotter than the Mercury itſelf; for if a Drop or two of Water be in a froſty Seaſon ſprinkled both upon the upper Part of the Tube, ſuppos'd to be full of *Fire*, and on the lower that is full of Mercury, they will in each Place freeze alike; ſo that there is no more pure *Fire* in a perfect *Vacuum* than in any other Place.

But whereas it has been ſaid, that *Fire* is found in all Bodies: To prove this, ſet Gold againſt the *Vacuum* before-mention'd, and this Gold, tho' the moſt ponderous of all Bodies, will not contain more *Fire* than *Huygens*'s *Vacuum*, as appears from the Thermometer.

But the *Fire* in Gold, when ready to fuſe, is pure *Fire*; for a Maſs of this being once heated red-hot, will retain this *Fire* perfectly for three Days: Nay the Prince of *Mirandola* and others have kept Gold ignited for two Months without any Diminution of Weight.

Mr. *Graveſande*, *Phyſ. Element.* ſays, That Bodies of any Kind being violently mov'd againſt one another, will grow hot by ſuch Friction, and this to a conſiderable Degree, which ſhews that all Bodies have *Fire* in them: For *Fire* may be put in Motion, and ſeparated from a Body by ſuch rubbing, but can never be generated that Way.

Mr. *Boyle*, *Mech. Prod.* of *Heat*, ſays, That whereas Quickſilver is allow'd to be the coldeſt of all Fluids, inſomuch that many deny that it will produce any Heat by its immediate Action on any other Body, and particularly on Gold; but ſeveral Trials have aſſured me, that a particular Mercury may by Preparation be inabled ſuddenly to inſinuate itſelf into the Body of Gold, whether calcin'd or crude, and become manifeſtly hot with it in leſs than two or three Minutes.

Mr. *Graveſande* ſays, That Quickſilver contains *Fire*, is evident hence, that if you ſhake it about in an exhauſted Glaſs, it will appear all luminous.

Elementary Fire of itſelf always lies conceal'd, nay, it may be perfectly undiſcoverable, where it is in the greateſt Quantity, as is evident in the Torrid Zone, where the Snow never melts, notwithſtanding the great Abundance of *Fire*.

This *Fire*, in itſelf thus perfectly latent, may diſcover itſelf to be preſent by five Effects; 1ſt, By rarefying Bodies, and particularly Air; 2dly, By Light; 3dly, By Colour; 4thly, By Heat; and 5thly, By Burning.

That there is a good Quantity of *Fire* even in the coldeſt Places, and in the coldeſt Bodies, is confirmed by the following Experiment: If you take two large Iron Planes, and rub them briſkly together in *Iceland*, which is only twelve Degrees ſhort of the North-Pole, in the moſt froſty Seaſon, and at Midnight, they will grow warm, glow, ſhine, and heat to ſuch a Pitch, as not only to rarefy the Spirit in the Thermometer, but even to ignite, and at laſt to fuſe.

Now the *Fire* here found is either created *de novo*, or it was there before; but nobody will aſſert its Creation, and accordingly, unleſs it be furniſh'd with a proper Fuel, it will be ſoon diſſipated again, but not annihilated, and of conſequence it pre-exiſted, and it appears to be true *Fire* by its rarefying the Spirit in the Thermometer.

From this, and many other Experiments, it is evident, that *Fire* is always found in all Parts of Space, and in all Bodies equally ſpread on the utmoſt Top of the higheſt Mountain, as in the ſubject Valley, or in the deepeſt Cavern under-ground, and in every Climate, and at every Seaſon.

The equable Diſtribution of *Fire* in all Places being prov'd, it ſhould thence follow, that there is the ſame Degree thereof every where; which would really be ſo, were it not that *Fire* happens by one Means or other to be more collected in one Place than another.

But, notwithſtanding, the equable Difference, *&c.* of Fire through all the Mundane Space, does not hinder, but that, to our Senſes, it appears very unequal in different Places: And hence we have two vulgarly reputed Sources or Funds of Fire, viz. in the Sun, and the Centre of the Earth.

As for the firſt, we have the concurrent Opinions of the Philoſophers of all Ages, but one excepted, who held the Sun to be cold.

As to the ſecond, the *central Fire*; it is manifeſt that there is an ample Proportion of *Fire* under ground; and even, that

Fire appears much more abundant there than on the Surface; ſo that at leaſt, a *ſubterraneous Fire* muſt be granted.

Thus they who dig Mines, Wells, *&c.* conſtantly obſerve, that while they are but a little below the Surface, they find it a little cool, and as they proceed lower it proves much colder, as being then beyond the Reach of the Sun's Heat, inſomuch that Water will freeze almoſt inſtantaneouſly; and hence is the Uſe of Ice-Houſes.

But a little lower, about forty or fifty Feet deep, it begins to grow warmer, ſo that no Ice can bear it; and then the deeper they go ſtill the greater the Heat; till at length it endangers the Stoppage of Reſpiration, and puts out their Candles: If they venture yet farther with a lighted Candle, the Place ſhall be immediately found full of Flame, as once happen'd in the Coal-Pits in *Scotland*, where an hardy Digger deſcending to an unuſual Depth, with a Light in his Hand, the Fumes, which were there found very copious, caught Fire thereby, and burnt the whole Mountain down.

Therefore it ſeems as if Nature had lodg'd another Sun in the Centre of the Earth, to contribute on its Part to the giving of Motion to Bodies, and for the promoting of Generation, Nutrition, Vegetation, Germination, *&c.* of Animals, Vegetables, and Foſſils.

As to the Origin of this ſubterraneous Sun, ſome Doubt whether it were form'd there in the Beginning, like the Sun in the Firmament, or gradually produc'd by a ſecondary Collection of vague *Fire* into this Place.

What makes in Favour of the former Opinion, are Vulcano's, or burning Mountains, which ſeem to have exiſted from the firſt Ages; for the Flames of Mount *Ætna* are mention'd as of great Antiquity; and there are likewiſe ſuch Fountains found in the coldeſt Regions, viz. *Nova Zembla*, and *Iceland*, as well as the hotteſt, as *Borneo*, &c.

It cannot be reaſonably pretended, ſays Mr. *Boyle*, that the ſubterraneous Heat proceeds from the Rays of the Sun, ſince they heat not the Earth above ſix or ſeven Feet deep, even in the Southern Countries; and if the lower Part of the Earth were of its own Nature cold, and receiv'd the Heat it affords only from the Sun and Stars, the deeper Men deſcend therein, the leſs Degree of Heat and Steams they would meet with.

The Sun contributes much in bring *Fire* to light, by reaſon of his rapid Motion round his Axis, whereby the fiery Particles, every where diffus'd, are directed and determin'd in parallel Lines towards certain Places where its Effects become apparent.

And from thence it is that the *Fire* is perceiv'd by us when the Sun is above; but that when he diſappears, his Impulſe or Preſſion being then taken away, the Fire continues diſpers'd at large through the Ethereal Space.

There is not, in effect, leſs Fire in our Hemiſphere in the Night-time than there is in the Day-time, only it wants the proper Determination to cauſe it to be perceiv'd.

The Effects of *Elemental Fire* may be increaſed divers Ways; *viz.* firſt, by *Attrition*, or a ſwift rubbing or agitating one Body againſt another. This is very manifeſt in Solids: The Attrition of a Flint againſt a Steel produces Sparks of *Fire:* And likewiſe in Fluids, the violent Agitation of Cream, by churning, will produce a ſenſible Warmth, and ſeparate it into Butter; and this Effect is render'd ſtill more diſcernible by a Barometer.

And the Heat of Animal Bodies is owing to the Agitation and Attrition of the Parts of theſe Juices againſt each other, and the Sides of the Veſſels.

The ſecond Manner of increaſing the Effect of *Elementary Fire*, is by throwing a Quantity of moiſt or green Vegetables, cut down while full of Sap, into a large Heap, and preſſing them cloſe down; by which they grow warm, hot, ſmoak, and break out into Flame.

A third Way, is by mixing certain cold Bodies: Thus Water and Spirit of Wine, being firſt warm'd, grow much hotter by being mixed; alſo Oil of Cloves, Cinnamon, *&c.* being mixed with Spirit of Wine, become exceeding hot, and burſt forth like Vulcano's.

The like Effects may be had from ſeveral hard and dry Bodies, as Sulphur and Steel-filings.

To conclude: Of *Fire*, and the Effects thereof, depend all Fluidity of Humours, Juices, *&c.* all Vegetation, Putrefaction, Fermentation, Animal Heat, *&c.*

As all the four Elements, *Water*, *Air*, *Earth*, and *Fire*, are very conducive to the Work of Vegetation, and no one of them more than this of *Fire*; I conclude, that theſe few Hints, which I have collected from the moſt approved Authors, concerning the Nature and properties of it, as they may be uſeful, would not be unacceptable to the ingenious and ſtudious Practiſers of *Horticulture*, which induced me to inſert them here. See alſo the Article *Heat*.

FIR-TREE. *Vide* Abies.

FISTULAR FLOWERS, [*Flores Fiſtulares*, of *Fiſtula*, Lat. a *Pipe*] ſuch as are compounded of many long, hollow, ſmall Flowers like Pipes.

FLAMMULA JOVIS. *Vide* Clematis.

FLESH, (among *Botaniſts*) is all the Subſtance of any Fruit that is between the Outer Rind and the Stone, or that Part of any Root that is fit to be eaten.

FLORIFEROUS, [*florifer*, Lat.] bearing Flowers.

FLORIST, One who is converſant with, or ſkill'd in Flowers.

FLORULENT, FLORULOUS, [*florulentus*, *florulus*, Lat.] Flowery, full of Flowers; alſo Bloſſoming.

FLOS AFRICANUS. *Vide* Tagetes.

FLOS PASSIONIS. *Vide* Granadilla.

FLOS SOLIS. *Vide* Corona Solis.

FLOS TRINITATIS. *Vide* Viola.

FLOWER: A *Flower* is a natural Production which precedes the Fruit, and yields the Grain or Seed. Tho' a *Flower* is a Thing ſo well known, yet the Definition of this Part of a Plant is as various almoſt as the Authors who define it. *Jungius* defines it to be the more tender Part of a Plant, remarkable for its Colour, or Form, or both, cohering with the Fruit. Yet this Author himſelf confeſſes that this Definition is too narrow; for ſome of thoſe Bodies which he allows to be Flowers, are remote from the Fruit.

Mr. *Ray* ſays, it coheres, *for the moſt part*, with the Rudiments of the Fruit. Thus the Words *for the moſt part*, are hardly to be admitted into Definitions.

Tournefort defines it to be *a Part of a Plant* very often *remarkable for its peculiar Colours*, for the moſt part *adhering to the young Fruit*, *to which* it ſeems *to afford the firſt Nouriſhment*, *in order to explicate its moſt tender Parts*. Which Definition is ſtill more deficient than the preceding, by this uncertain Mode of Expreſſion.

Pontedera, Profeſſor of Botany at *Padua*, defines it to be *a Part of a Plant, unlike the reſt in Form and Nature*; *always, when the Flower has a Tube, adhering or fixed very near to the Embryon, to the Uſe of which it is ſubſervient*; *but if the Flower has no Tube, not adhering to the Embryon*. Which Definition is not much clearer, being ſcarce intelligible to any Perſon who has not ſtudied Botany a conſiderable Time; as Mr. *John Martyn* well obſerves; and alſo, that it is liable to this Objection, that it may include ſome Parts, which no Perſon ever called by the Name. For a Root, or a Stalk, or a Leaf, are Parts of a Plant unlike the reſt in Form and Nature, having no Tube, and ſo adhering to no Embryons; and thus, by *Pontedera*'s Definition, are Flowers.

Monſ. *Jeſſieu*, the *Paris* Profeſſor, ſeems not to have ſucceeded much better in this Affair; he ſays, *that it is properly call'd a Flower which is compos'd of Chives, and a* Piſtillum, *and is of Uſe in Generation*. But this is too defective; for that there are many Plants in which the *Piſtillum* or Stile is found a conſiderable Diſtance from the Chives; many Flowers that have no *Piſtillum*, whether that Word be taken to ſignify the Embryon of the Fruit, or its *Appendix*; and many which have no Chives.

But the late Monſ. *Vaillant* ſeems to be happier, in forming a clearer Idea of this Part of a Plant. We find, in the Lecture he read in the Royal Garden at *Paris*, that the *Flowers*, ſtrictly ſpeaking, ought to be reckon'd the Organs which conſtitute the different Sexes in Plants; ſeeing they are ſometimes found without any Covering, and that the Coats, or Petals, which immediately incompaſs them, are deſign'd only to cover and defend them: But (ſays he) as theſe Coats are the moſt conſpicuous and moſt beautiful Part of the Compoſition, which is call'd by the Name of *Flower*; to theſe Coats therefore I give the Name of *Flower*, of whatſoever Structure or Colour they be, whether they incompaſs the Organs of both Sexes together, or contain only one of them, or only ſome Part, depending on one of them, provided always that they be not of the ſame Figure of the Leaves of the Plant.

But, in my Opinion, Mr. *John Martyn* has been happier, in his Definition of a *Flower*, than all thoſe above-mention'd: He defines a *Flower* to be the *Organs of Generation of both Sexes adhering to a common* Placenta, together with their common Coverings; or of either Sex ſeparately, with its proper Coverings, if it have any.

The Parts of a *Flower* are, 1. The *Ovary*, which is the Rudiment of the Fruit, and ſo is properly the Female Organ of Generation.

2. The *Stile*, which is a Body accompanying the *Ovary*, either ariſing from the Top of it, or ſtanding as an *Axis* in the Middle, with the Embryons of the Seeds round it,

3. The *Summits*, or *Apices*, which are thoſe Bodies that contain the Prolifick Power, analogous to the Male Sperm in Animals; and generally hang upon ſlender Threads, which are call'd the *Chives*.

The *Petals* are thoſe tender, fine-coloured Leaves which are generally the moſt conſpicuous Parts of a *Flower*.

The *Impalement*, or *Calyx*, is thoſe tender Leaves which cover the other Parts of a *Flower*.

Flowers, according to the Number of their *Petals*, are call'd Monopetalous, Dipetalous, Tripetalous, Tetrapetalous, *&c*.

The Structure of *Flowers* is indeed very various: But, according to Dr. *Grew*, the Generality have theſe three Parts in common, *viz.* the *Impalement*, the *Foliation*, and the *Attire*.

Mr. *Ray* reckons that every perfect *Flower* has the *Petala*, *Stamina*, *Apices*, and *Stylus* or *Piſtil*: and ſuch as want any of theſe Parts, he accounts imperfect *Flowers*.

In moſt Pants there is a *Perianthum*, *Calyx* or *Flower-cup*, which is of a ſtronger Conſiſtence than the *Flower* itſelf, and deſign'd to ſtrengthen or preſerve it.

Flowers are diſtinguiſh'd into *Male*, *Female*, or *Hermaphrodite*.

The *Male Flowers* are thoſe in which are the *Stamina*, but bear no Fruit; the ſame which *Botaniſts* call *Stamineous Flowers*.

The *Female Flowers* are ſuch as contain the *Piſtil*, which is ſucceeded with Fruit, and are call'd *Fruitful* or *Knitting Flowers*.

The *Hermaphrodite Flowers* are ſuch in which the two Sexes are contained; *i. e.* the Male and Female Parts are found in the ſame *Flower*, which are the moſt general Kind; ſuch are the *Daffodil*, *Lily*, *Tulip*, *Althæa*, *Geranium*, *Roſemary*, *Sage*, *Thyme*.

The Structure of Parts is much the ſame in thoſe where the Sexes are divided; the Difference between them conſiſting in this, that the *Stamina* and *Apices*, i. e. the Male Parts in theſe are ſeparate from the *Piſtils*, being ſometimes on the ſame Plants, and ſometimes on different ones.

Among the Plants which bear both Male and Female Parts, but at a Diſtance from each other, are reckon'd the *Cucumber*, *Melon*, *Gourd*, *Turkey Wheat*, *Turnſol*, *Wall-nut*, *Oak*, *Beech*, &c.

FLOWERAGE: The ſetting of ſeveral Sorts of *Flowers* together in Huſks, and hanging them up in Strings.

FLUIDITY, [*Fluiditas*, of *fluere*, Lat. *to flow.*] Having Occaſion to mention *Fluids* and *Fluidity*, in ſpeaking of the Properties of the Elements *Air*, *Water*, *Fire*, &c. I thought neceſſary, in this Place, to give the following Account of that Property, which I have extracted from the moſt approved Authors.

A *Fluid*, or *Fluid Body*, is, by ſome, defin'd to be a Body whoſe Particles are but weakly connected, their mutual Coheſion being, in a great meaſure, prevented from ſome external Cauſe: In which Senſe a *Fluid* ſtands oppos'd to a *Solid*; and is, by the excellent Sir *Iſaac Newton*, defin'd to be one whoſe Parts eaſily give Place, or move out of the Way, on any Force impell'd upon them, and by that Means do ſo eaſily move one over another. Which Definition is much better than that of *Des Cartes*, That a *Fluid* is a Body whoſe Parts are in continual Motion: Becauſe 'tis neither apparent that the Parts of all *Fluids* are ſo; nor, that the Parts of ſome *Solid Bodies* are not ſo.

Fluidity is the State or Affection of Bodies, which denominates or renders them *fluid*, and ſtands in direct Oppoſition to *Firmneſs* and *Solidity*.

It is diſtinguiſh'd from *Liquidity* and *Humidity*, in that the Idea of *Fluidity* is abſolute, and the Property contain'd within the Thing itſelf; whereas that of *Humidity* is relative, and implies Wetting, or adhering, *i. e.* ſomething that gives us the Senſation of Wetneſs or Moiſture, and would have no Exiſtence, but for our Senſes.

Thus melted Metals, Air, Æther, and even Smoke, and Flame itſelf, are *fluid* Bodies, and not *liquid* ones; the Parts of them being actually dry, and not leaving any Senſe of Moiſture. See *Liquidity* and *Humidity*.

Fluidity ſeems to conſiſt in this; That the Parts of any Bodies being fine and ſmall, are ſo diſpos'd by Motion and Figure, as that they can eaſily ſlide over one another's Surfaces all manner of ways. Mr. *Boyle* alſo obſerves, That it is requiſite they ſhould be variouſly and ſeparately agitated to and fro, and that they ſhould touch one another but in ſome Parts only of their Surfaces. And the ſame Gentleman ſays, in his *Hiſtory of Fluidity*, That the Conditions requiſite to conſtitute a *fluid Body*, are chiefly the three following:

1ſt: The *Minuteneſs* or *Smallneſs* of its Parts: Thus we ſee the Fire, by dividing Metals into Parts very fine and ſmall, will melt them, and make them fluid. And after the ſame manner do acid Menſtruums diſſolve them, ſuſpend their Liquor, and render them fluid. And that Fire turns the hard Body of common Salt almoſt wholly into a Liquor by Diſtillation: Tho' 'tis not improbable but that the Shape and Figure of theſe ſmall Parts may conduce much towards producing this Quality of *Fluidity*; for it is found in the Diſtillation of *Olive* Oil, (which is a Fluid made only by Preſſure) that moſt of the Oil will, by the Action of the Parts of the Fire, (if it be done in a Retort) be turn'd into a kind of conſiſtent Subſtance like Butter.

Likewiſe *Mercury*, whoſe Parts are, without doubt, much groſſer than thoſe of Oil and Water, is yet more fluid than either of them.

2dly: It ſeems requiſite to *Fluidity*, that there be Store of Vacuities, or vacant Spaces interſpers'd between the Corpuſcles of the fluid Body; for elſe there will not be Room for each Particle to continue its Motion and Agitation on the Surfaces of the neighbouring ones. For,

3dly: The chief Condition requiſite to conſtitute a fluid Body, is, that its Particles be agitated variouſly and apart, either by their own proper Motion, or by ſomething of Subſtance that tumbles them up and down by its Paſſage thro' them.

That this Qualification is chiefly requiſite to *Fluidity*, you may gather from that common Experiment of putting a little dry Powder of *Alabaſter*, or *Plaiſter of Paris*, finely ſifted, in a flat-bottom'd Veſſel over the Fire; for in a little Time it will boil like Water, and imitate all the Motions of a boiling Liquor; it will tumble variouſly over in great Waves *like that*; it will bear ſtirring with a Stick or Ladle without reſiſting, as it will do when cold; nay, if it be ſtirr'd ſtrongly near the Side of the Veſſel, its Waves will apparently daſh up againſt the Sides; yet if any of it be ſpeedily taken out, and laid on a Piece of Paper, you will ſee nothing but a dry Powder.

So that it is evident from hence, that there is a real Difference between a *fluid Body* and a *wetting Liquor*; for not only this boiling Powder and melted Metals, but the Air and Æther, and even Flame itſelf, are properly fluid Bodies, tho' not moiſt Liquors.

This ingenious Gentleman found alſo, that, by blowing the Smoke of *Roſemary* into a Glaſs Pipe, and then holding the Pipe (when fill'd) upright, the Surface of the Smoke would accommodate itſelf to a level Situation; and which Way ſoever the Tube was inclin'd, the Superficies of the Smoke would be parallel to the Horizon; and when the Glaſs was much inclin'd, would run along it like Water.

From whence he infers, that, in order to the rendring a Body fluid, there is no Need that its Parts ſhould be cloſely condens'd as thoſe of Water are.

And Dr. *Hook*, in his *Micograph.* p. 12. preſents us with a very pretty Experiment or two to prove this Account of *Fluidity*; viz. That a Diſh of Sand being ſet on a Drum-head, briſkly beaten by the Sticks, or on the upper Stone of a Mill, turning ſwiftly round on the (empty) lower one, it in all reſpects emulates the Properties of a fluid Body; for a heavy Body will immediately ſink in it to the Bottom, and a light one emerge to the Top; each Grain of Sand hath a conſtant vibrating, dancing Motion; and if a Hole be made in the Side of the Diſh, the Sand will ſpin out like Water.

The Corpuſcular Philoſophy, before it was wonderfully improv'd by Sir *Iſaac Newton*, did not go to the Bottom of this Matter; for it gave no Account of the Cauſe of the chief Condition requiſite to conſtitute a fluid Body, viz. *the various Motions and Agitations of its Particles*: But this may, in a great meaſure, be accounted for, for if it be ſuppoſed to be one of the primary Laws of Nature, that as all Particles of Matter do attract one another when they come within a certain Diſtance, ſo likewiſe do they fly away from, and avoid one another, at all greater Diſtances from one another.

For then, tho' their common Gravity may keep them together in a Maſs, (it may ſometimes be) together with the Preſſure of other Bodies upon them, yet their continual Endeavours to avoid one another *ſingly*, and the adventitious Impulſes of Light, Heat, or other external Cauſes, may make the Particles of Fluids continually move round about one another, and ſo produce this Quality.

It is indeed a Difficulty not eaſily got over, to account for the Particles of Fluids always keeping at ſuch a Diſtance from one another, as not to come within the Sphere of one another's Attraction.

The Fabrick and Conſtitution of that fluid Body, Water, is amazing; that a Body ſo very rare, and which has a vaſt Over-proportion of Pores, or interſper'd Vacuity, to ſolid Matter, ſhould yet be perfectly incompreſſible by the greateſt Force; and yet this Fluid is eaſily reducible to that firm, tranſparent, friable Body which we call Ice, by being only expos'd to a certain Degree of Cold.

One would think, that tho' the Particles of Water cannot come near enough to attract each other; yet the intervening frigorifick Matter doth, by being mingled *per minima*, ſtrongly attract them, and is itſelf likewiſe ſtrongly attracted by them, and ſo wedges or fixes all the Maſs into a firm Body; which ſolid Body loſes its Solidity again, when, by Heat, the *Vinculum* is ſolved, and theſe frigorifick Particles are disjoin'd from thoſe of the Water, and are forced to fly out of it; and, perhaps, juſt thus may the Fumes of Lead fix Quickſilver.

When a firm, ſolid Body, ſuch as a Metal, is, by Heat, reduc'd into a Fluid, doth not the Fire disjoin and ſeparate its conſtituent Particles, which *mutual Attraction* caus'd to cohere before, and keep them ſuch a Diſtance from each other, as that they are without the Sphere of one another's Attraction as long as that violent Motion laſts? And don't they, when that is over, and the Heat is flown out, come nearer to, attract one another, and coaleſce again?

As therefore the Cauſe of Coheſion of the Parts of ſolid Bodies appears to be their mutual Attraction, ſo the chief Cauſe of *Fluidity* ſeems to be a contrary Motion impreſs'd on the Particles of Fluids, by which they avoid and fly one another, as ſoon as they come at, and as long as they keep at ſuch a Diſtance from each other.

It is obſerved alſo in Fluids, that the Direction of their Preſſure againſt the Veſſels which contain them, is in Lines perpendicular to the Sides of ſuch Veſſels; which Property being the neceſſary Reſult of the Particles of any Fluids being ſpherical, it ſhews that the Parts of all Fluids are ſo, or of a Figure nearly approaching thereto.

Dr. *Clark* ſays, That if the Parts of a Body do not touch each other, or eaſily ſlide over one another, and are of ſuch a Magnitude as that they may be eaſily agitated by Heat, and the Heat be ſufficiently great to agitate them; tho', perhaps, it may be leſs than ſuffices to prevent Water from freezing; or even tho' the Parts be not actually mov'd, yet if they be ſmall, ſmooth, ſlippery, and of ſuch a Figure and Magnitude, as diſpoſes them to move and give way, that Body is fluid:

And yet the Particles of ſuch fluid Bodies do, in ſome meaſure, cohere; as is evident hence, that *Mercury*, when well purg'd of Air, will be ſuſtain'd in the Barometer to the Height of ſixty or ſeventy Inches; that Water will aſcend in capillary Tubes, even in *Vacuo*; and that the Drops of Liquors in *Vacuo* run into a ſpherical Form, as adhering by ſome mutual Coheſion, like that between poliſh'd Marble Planes.

To this may be added, That theſe fluid Bodies, if they conſiſt of Particles, which are eaſily intangled with each other, as *Oil*; or if they be capable of being ſtiffen'd by Cold, and joined by the Interpoſition of certain *Cunei* or Wedges, as *Water*, they are eaſily render'd hard: But if their Particles are ſuch as can neither be intangled, as *Air*, nor ſtiffen'd by Cold, as *Quickſilver*, then they never grow hard and fixed.

In ſhort, the *Carteſians* define a *Fluid* to be a Body, the Parts of which are in continual inteſtine Motion; and Dr. *Hook*, Mr. *Boyle*, and Dr. *Boerhaave*, tho' they differ in Opinion widely from *Carteſianiſm*, ſubſcribe to the Definition, and alledge Arguments to prove, that the Parts of Fluids are in continual Motion; and even that it is this Motion which conſtitutes Fluidity; and the latter of them aſcribes this and all Motion to Fire. See *Fire*.

Fluids then are either natural, as *Water*, and *Mercury*; or animal, as *Blood*, *Milk*, *Bile*, *Lympha*, *Urine*, &c. or factitious, as *Wines*, *Spirits*, *Oils*, &c.

FŒNICULUM; [This Plant ſeems to take its Name of *Fœnum*, Lat. *Hay*, q. d. *ſmall* or *fine Hay*; but ſome derive it from *Venus*, becauſe this Plant ſows itſelf among others, and becomes fruitful, or becauſe it provokes the *Semen* in Men.] Fennel.

The *Characters* are;

It is an umbelliferous Plant, whoſe Leaves are divided into capillaceous Jags: The Petals of the Flower are intire, and plac'd orbicularly, expanding in form of a Roſe: Each Flower is ſucceeded by two oblong, thick, gibboſe Seeds, which are channel'd on one Side, and plain on the other.

The *Species* are;

1. Foeniculum *vulgare Germanicum. C. B.* Common Fennel.
2. Foeniculum *foliis atro-virentibus. H. Edin.* Common Fennel, with dark-green Leaves.
3. Foeniculum *dulce. C. B.* Sweet Fennel.
4. Foeniculum *ſylveſtre. C. B.* Wild Fennel.
5. Foeniculum *dulce Azoricum. Pluk. Almag. Finochia*; vulgo.

The firſt Sort is ſo common in *England*, that it will be needleſs to ſay any thing concerning it.

The ſecond Sort is a Variety of the firſt, which is very common amongſt it in moſt Gardens in *England*.

The third Sort is the *Sweet Fennel*, whoſe Seeds are us'd in Medicine: This is by many People ſuppos'd to be only a Variety of the common Sort, or at leaſt that the common Sort is a Degeneracy from it; but this is a great Miſtake, for the *Sweet Fennel* is an annual Plant, and never ſurvives a Winter with us, whereas the common Sort will abide many Years.

The firſt and ſecond Sorts are promiſcuouſly brought to the Markets for Kitchen Uſes. Theſe are propagated by ſowing the Seeds ſoon after they are ripe; and when the Plants are come up, they ſhould be either tranſplanted or houghed out to the Diſtance of ſixteen or eighteen Inches, Plant from Plant, for they will ſpread and increaſe in Bulk greatly: Their Roots will abide many Years, but you muſt be careful not to ſuffer their Seeds to ſhed upon the Ground; for the Plants will come up, and over-run every thing that grows near them, and they are with much Difficulty extirpated.

The *Sweet Fennel* is an Annual, and muſt be ſown upon a warm Soil, and in an open Situation in *February* or the Beginning of *March*; and when theſe Plants are come up, they ſhould be houghed out to ten Inches or a Foot Diſtance from each other, and kept clear from Weeds: In *Auguſt* this Plant will perfect its Seeds, and ſoon after the Roots will decay. The Seeds of this Plant which are ſav'd in *England*, are not near ſo good as thoſe which are brought from abroad, which are generally imported at a very reaſonable Price, ſo that it is not worth cultivating with us.

The *Finochia* is a Plant which of late Years has been introduced into the *Engliſh* Gardens, where it is cultivated as a Sallad-herb, and is by ſome People very much eſteem'd, tho' the Generality of *Engliſh* Palates do not at preſent reliſh it; but ſince it is likely to become of more general Uſe, I ſhall give a ſhort Account of its Culture.

Firſt, you muſt provide yourſelf with a Parcel of good Seeds from *Italy*, for thoſe ſav'd in *England* are very apt to degenerate: In *February* you may ſow ſome for the firſt Crop, which ſhould be in a warm Situation, and upon a light dry Soil. The manner of doing this is as follows: After having well dug and levell'd the Ground ſmooth, you ſhould make a ſhallow Rill by a Line, into which you muſt ſcatter your Seeds pretty thin; for if your Plants are ſix Inches aſunder in the Rows, it will be full near enough; but however, you muſt expect ſome of your Seeds to fail; and therefore you ſhould ſcatter them about two Inches Diſtance; then cover the Seeds about half an Inch thick with Earth, laying it ſmooth: Theſe Rills ſhould be made ſixteen Inches aſunder, or more, that there may be Room to clear the Ground, as alſo to earth up the Plants when they are full grown. When the Plants come up, which will be in about three Weeks or a Month after ſowing, you muſt with a ſmall Hough cut up all the Weeds between them, and cut out the Plants to about four Inches Diſtance; and as they advance, and the Weeds ſpring again, ſo they ſhould, from Time to Time, be hough'd: And at the laſt Time of thinning them, they ſhould be left ſix or ſeven Inches aſunder at leaſt. If your Kind be good, the Stems of the Plants will increaſe to a conſiderable Bulk juſt above the Surface of the Ground, which Part ſhould be earth'd up in the manner of Celery, to blanch, about a Fortnight before it is us'd, and this will cauſe it to be very tender and criſp.

Your ſecond Crop ſhould be ſown about three Weeks after the firſt, and ſo continue ſowing every three Weeks or a

Month till *July* ; after which Time it will be too late for the Plants to come to any Perfection. But you ſhould obſerve to ſow in *April* and *May* on a moiſter Soil than that which you ſow'd the firſt on : As alſo what you ſow in the latter Part of *June*, or the Beginning of *July*, ſhould be ſown on a drier Soil, and in a warmer Situation ; becauſe this Crop will not be fit for Uſe till late in the Autumn, and therefore will be ſubject to Injuries from too much wet or cold Weather, if on a moiſt Soil. But as the Ground is very often extreme dry in *June* and *July*, and ſo the Seeds are more apt to miſcarry, or not to come up, you ſhould therefore obſerve to water and ſhade the Beds where this Seed is ſown at that Seaſon until the Plants come up.

A ſmall Bed of this Plant will be ſufficient at each Sowing for a middling Family ; and for a large Family, a Bed of about twenty Feet long, and four Feet broad, will be full enough at a Time.

FŒNUM BURGUNDIACUM. *Vide* Medica Sativa.

FŒNUM GRÆCUM, [*Grecian Hay*, is ſo call'd, becauſe being dry'd, it looks like Hay, and the Seeds were brought from *Greece*. It is alſo call'd *Buceras*, from Βοῦς an *Ox*, and Κέρας a *Horn*, q. d. *Ox-horn*, from the Shape of the Huſk ; alſo *Ægoceras*, of Αἲξ αἰγὸς a *Goat*, and Κέρας a *Horn*, q. d. *Goat's-horn*, from the ſame Cauſe.] Fenugreek.

The *Characters* are ;

It hath a papilionaceous Flower, out of whoſe Impalement riſes the Pointal, which afterwards becomes a Pod ſomewhat plain, ſhap'd like a Horn, and full of Seeds, for the moſt part Rhomboid, or Kidney-ſhap'd.

The *Species* are ;

1. Foenum Græcum *ſativum. C. B.* Common Fenugreek.
2. Foenum Græcum *ſylveſtre. C. B.* Wild Fenugreek.
3. Foenum Græcum *ſylveſtre alterum polyceration. C. B.* Another wild Fenugreek with many Pods.

There are ſeveral other Varieties of this Plant, which are preſerv'd in curious Botanick Gardens : but as they are Plants of little Uſe or Beauty, ſo I ſhall omit mentioning them here.

The firſt Sort here mentioned, is that of which the Seeds are us'd in Medicine.

The other two Sorts are Varieties which are preſerv'd in ſome Gardens. They may be propagated by ſowing their Seeds in *February* or *March* upon a light Soil, and in an open Expoſure. The Plants, when they come up, ſhould be ſingled out to about four or five Inches Diſtance each Way ; and the Ground ſhould be conſtantly kept clear from Weeds, which, if ſuffer'd to grow, would ſoon overſpread and deſtroy the Plants : But you muſt obſerve, theſe Plants will not bear tranſplanting, therefore they ſhould be ſown in the Places where they are to remain. In *June* they will flower, and their Seeds will be perfected in *Auguſt*.

This Plant is cultivated in the open Fields in the South Parts of *France* and *Italy*, from whence the Seed is brought to *England* for Uſe ; for it is too uncertain a Crop to cultivate here, being very apt to miſcarry in cold wet Summers.

FOLIATION, is one of the Parts of a Flower of a Plant, being a Collection of thoſe fine-colour'd Leaves which conſtitute the Compaſs of the Flower.

FOOT-HUSKS are ſhort Heads out of which Flowers grow.

FOUNTAINS are Sources or Springs of living Water ariſing out of the Ground. As to the Original of them, ſee under the Article *Springs*.

Of artificial *Fountains* there is a great Variety ; the Mechaniſm of which not being to my Purpoſe, I will not dwell upon it : Tho' I may aſſert, that they are not only great Ornaments to a fine Garden, but alſo of great Uſe. But they ought not to be plac'd too near the Houſe, by reaſon of the Vapours that ariſe from the Water, which may be apt to ſtrike a Damp to the Walls, and ſpoil the Paintings, *&c.* and the Summer Vapours may cauſe a Malignity in the Air, and ſo be prejudicial to the Health of the Family ; and likewiſe the Noiſe may be incommodious in the Night.

Fountains in a Garden ſhould be ſo diſtributed, that they may be ſeen almoſt all at one Time, and that the Water-ſpouts may range all in a Line one with another ; which is the Beauty of them ; for this occaſions an agreeable Confuſion to the Eye, making them to appear to be more in Number than really they are. See *Jet d'Eau*, *Springs*, *Vapours*, *Water*, &c.

FRAGARIA ; [is ſo call'd for its fragrant, aromatick Scent] Strawberry.

The *Characters* are ;

It hath a perennial fibroſe Root : The Leaves are vein'd, growing upon each Foot-ſtalk : The Stalks trail upon the Ground : The Cup of the Flower conſiſts of one Leaf, which is divided into ten equal Parts, and expands in form of a Star : The Flower conſiſts for the moſt part of five Leaves, which expand in form of a Roſe, *and have many* Stamina *in the Middle, round the Baſe of the Ovary : The Fruit is globoſe or oval, and conſiſts of a fleſhy, eatable Pulp, full of Protuberances.*

The *Species* are ;

1. Fragaria *vulgaris. C. B.* Common *or* Wood-Strawberry.
2. Fragaria *fructu albo. C. B.* Common Strawberry, with white Fruit.
3. Fragaria *fructu parvi pruni magnitudine. C. B.* The Hautboy Strawberry ; *vulgo.*
4. Fragaria *Virginiana, fructu coccineo. M. H. Virginian* Strawberry, with ſcarlet Fruit.
5. Fragaria *Chilienſis, fructu maximo, foliis carnoſis hirſutis* ; vulgo *frutilla. Frez. Voy.* Large *Chili* Strawberry.
6. Fragaria *fructu globoſo majore ſuaviſſimo.* The Globe Hautboy Strawberry.
7. Fragaria *fructu parvo ex albo vireſcente.* Strawberry, with a ſmall greeniſh white Fruit.

The firſt and ſecond Sorts of *Strawberry* are found wild in the Woods in divers Parts of *England*, from whence the Plants are taken and tranſplanted into Gardens ; by which the Fruit is improv'd. The beſt Seaſon for this Work is in *September*, that the Plants may be rooted in their new Quarters before the Froſt begins, which is very apt to looſen the Earth ſo much about their Roots, that when the Froſt goes off, the Plants are apt to be turn'd out of the Ground. They may alſo be tranſplanted in *February* ; but then, if the Spring ſhould prove dry, they will require a great Expence of Water to preſerve them alive.

The Soil which is moſt proper for theſe Plants, is a fre hazily Loam, not over-rich, which would cauſe the Plants t ſpread and flouriſh, but they would not be ſo fruitful as upo a moderate Soil. The Ground ſhould be well dug, and clear' from the Roots of all noxious Weeds ; and after it is levell' even, you muſt mark it out into Beds about three Feet and half wide, leaving a Path between each Bed two Feet broa for the Conveniency of walking between them to water a clean them, as alſo to gather the Fruit : In theſe Beds may planted four Rows of Plants, whereby they will be about Foot aſunder Row from Row ; and in the Rows they ſhou be planted at leaſt eight Inches diſtant Plant from Plant ; if they are planted nearer, they will in one Year's Time be thick, that they will not have Room to thrive. *Note*, t Diſtance here aſſign'd being for the Wood-Strawberry, whi is of the leaſt Growth, the other large growing Kinds m have a greater Share of Room, according to their differe Degrees of Growth ; as for Example, the *Scarlet Strawbe* ſhould be planted a Foot ſquare Plant from Plant, and *Hautboy* ſixteen or eighteen Inches Diſtance each Way ; a the *Chili Strawberry* twenty Inches or two Feet.

In the Spring of the Year, when the *Strawberries* begin flower, if the Seaſon be dry, you muſt obſerve to water th plentifully, otherwiſe the Flowers will fall away without p ducing any Fruit. You muſt alſo carefully clean your Beds *Strawberries* from Weeds from Time to Time, as they ſh require ; for if they are once ſuffer'd to over-bear the Pla they will decay in large Patches, and alſo greatly weaken thoſe that may continue alive. About *Michaelmas* you ſho clear off all the Weeds from the Beds, as alſo cut off the Strings or Runners from the Roots, pulling out all w Plants where they are too cloſe ; then dig up the Walks tween the Beds, burying the Seeds that came off in the B tom, and throw a little fine Earth over the Beds between Plants, being very careful not to lay it ſo thick as to bury Plants : This will greatly ſtrengthen them, and cauſe t Fruit to be larger and in greater Quantities, than they w be if left undreſs'd.

Theſe few Rules will be ſufficient, if duly obſerv'd, cultivating theſe Plants. I would only farther obſerve, theſe Beds will not continue bearing well more than Years ; therefore, in order to have a conſtant Supply, ſhould plant a freſh Plat of Ground a Year before you deſtroy the old Beds, otherwiſe (your young Plantation producing few or no Fruit the firſt Year) you will be deſtitute a whole Seaſon.

The *Wood Strawberry* is by many People preferr'd for the Firmneſs of its Fruit, and Delicacy of Flavour: Others greatly admire the Scarlet Sort for its Goodneſs, and the Hautboy is eſteem'd for the Largeneſs of its Fruit. But the Sort with white Fruit is by far the beſt flavour'd of all the Kinds, tho' it is a bad Bearer. The *Chili Strawberry* was brought firſt into *Europe* by Monſieur *Frezier*, Engineer to the late *French* King, and given to Monſieur *de Jeſſieu*, Profeſſor of Botany to the Royal Garden at *Paris*, who hath ſpread it into divers Parts of *Europe*. This Plant, Monſieur *Frezier* ſays, is cultivated in the Fields near *Chili* in great Plenty, and that it differs from the *European* Kinds, in having larger, thicker, and more hairy Leaves: The Fruit is generally as large as a Walnut, and ſometimes as big as an Hen Egg, of a whitiſh red Colour, and ſomewhat leſs delicious in Taſte than our *Wood Strawberries*. This has produc'd Fruit ſeveral Years in the Royal Garden at *Paris*, where Monſieur *Jeſſieu* aſſur'd me, it was commonly as large as a ſmall Apple. I brought ſome of the Plants from *Holland Anno* 1727, which thrive and increaſe exceedingly; but theſe bear very indifferently, and the Fruit being leſs delicate than the Hautboys, few Perſons care to propagate this Sort in *England*. Theſe Plants have been placed in the Sun, and cultivated with Care, but have never ſucceeded where they have been thus treated. I have obſerved, that they have ſucceeded beſt where they have grown under the Shade of Trees, in a loamy Soil, and little more Care taken of them than to keep them clear from Weeds.

The ſixth Sort is now much cultivated by moſt curious Perſons near *London*, it being a more plentiful Bearer than the common *Hautboy*, and is a better taſted Fruit. In a kindly Seaſon I have ſeen this Fruit as large as Walnuts, and of an extraordinary fine Flavour. This may be cultivated in the ſame Manner as the common *Hautboy* Strawberry, and muſt be planted at the ſame Diſtance.

The ſeventh Sort is a very firm Fruit, about the Size of the Wood Strawberry, or a little larger; this is greatly eſteemed for the Firmneſs of the Fruit, and the quick agreeable Flavour; which ſome Perſons have imagined to reſemble the *Pine-apple*, and from thence have given it the Name of the *Pine-apple Strawberry*. This may be propagated in the ſame Manner as the Wood Strawberry, but ſhould be every Autumn carefully diveſted of Suckers; otherwiſe they will grow very thick, and produce but little Fruit.

The *Chili* Strawberry, which is above deſcribed, is now but little eſteemed in *England*, the Fruit being ill-taſted. This Kind has produced Fruit of late Years in many Gardens; but in general the Fruit is not ſo large as thoſe of the *Globe Hautboy Strawberry*, and is of a very irregular Form: This Sort produces more Fruit, where they grow neglected, and under Shade, than when they are planted in an open Situation, and are cultivated with great Care.

FRANGULA; [is ſo call'd of *frangendo*, *breaking*, becauſe of the Brittleneſs of its Wood] Berry-bearing Alder.

The *Characters* are;

It hath roundiſh Leaves, ſomewhat like thoſe of the Alder-Tree, but ſmaller: The Flower conſiſts of five Leaves, which expand in form of a Roſe: The Flowers are ſucceeded by ſmall round Berries, in each of which are contain'd two ſmall flat Seeds.

The *Species* are;

1. Frangula, *ſive Alnus, nigra baccifera. Park. Theat.* Black Berry-bearing Alder.
2. Frangula *rugoſiore & ampliore folio. Tourn.* Berry-bearing Alder, with a larger and rougher Leaf.
3. Frangula *montana pumila ſaxatilis, folio ſubrotundo. Tourn.* Low Mountain rocky Berry-bearing Alder, with a round Leaf.
4. Frangula *montana pumila ſaxatilis, folio oblongo. Tourn.* Low Mountain rocky Berry-bearing Alder, with an oblong Leaf.
5. Frangula *ſempervirens, folio rigido ſubrotundo. Hort. Elth.* Ever-green Berry-bearing Alder, with a round ſtiff Leaf, commonly called the *Hottentot Cherry*.

The firſt Sort is very common in moiſt Woods in divers Parts of *England*, and is rarely cultivated in Gardens, except for Variety: It ſeldom grows above fourteen or ſixteen Feet in Height, and is not very regular in its Growth, ſo that as it is a Plant of no great Beauty, it leſs deſerves a Place in curious Gardens. It may be propagated by Layers, or from Suckers, which ariſe from the Foot of old Plants, and muſt be planted in a moiſt Soil, and a ſhady Situation, where it will thrive exceedingly.

The Fruit of this Tree is often brought into the Markets of *London*, and ſold for *Buckthorn-berries*; of which Cheat, all ſuch as make *Syrup of Buckthorn* ſhould be particularly careful: They may be eaſily diſtinguiſh'd by breaking the Berries, and obſerving how many Seeds are contain'd in each; the Berries of this Tree having but two, and thoſe of *Buckthorn* generally four Seeds in each Berry.

The ſecond Sort is leſs common than the former in *England*, but may be propagated in the ſame Manner as hath been directed for that Sort, and requires a moiſt Situation; this is much like the former in its Growth, and may be admitted for Variety.

The third and fourth Sorts are of humble Growth, ſeldom riſing above two Feet high; theſe grow on the *Pyrenean* Mountains, and are ſeldom preſerved unleſs in botanic Gardens for Variety: They may be increaſed by laying down their Branches, but muſt have a ſtrong Soil, ſomewhat drier than what has been directed for the two former.

The fifth Sort is a Native of *Africa*, and has been a long Time preſerved by the Curious in their Gardens, under the Title of *Ceraſus Hottentotorum*, or *Hottentot Cherry*; but it having produced Flowers and Fruit in the Garden of Dr. *James Sherard* of *Eltham*, is figured and deſcribed by Dr. *Dillenius*, in the *Hortus Elthamenſis*, by the Name I have here given it. This Plant may be propagated by Cuttings, which ſhould be the former Year's Shoots, and muſt be planted the latter End of *April*, in Pots filled with freſh rich Earth; which ſhould be plunged into a moderate Hot-bed of Tanners-bark, being careful to ſhade the Glaſſes in the Heat of the Day, as alſo to refreſh them often with Water; this muſt be duly obſerved, until the Cuttings have taken Root, which cannot be expected ſooner than the Middle of *July*, when they muſt be inured to bear the open Air by degrees; and toward the End of the Month, they muſt be taken out of the Hot-bed, and placed in the open Air, in a warm Situation, where they may be ſcreened from violent Winds; in this Place they may remain till the Beginning of *October*, when they muſt be removed into the Green-houſe, and placed in a warm Situation; and during the Winter Seaſon, they muſt be frequently refreſhed with Water, but this muſt not be given them in too large Quantities, while they continue in the Houſe. In the Spring theſe Plants may be ſhaken out of the Pots, and ſeparated, putting each into a ſmall Pot filled with freſh rich Earth, and placed in a ſhady Situation, until they have taken new Root; after which Time they may be expoſed to the open Air, with *Myrtles*, *Oranges*, and other hardy exotic Plants, till Autumn, when they muſt be houſed with thoſe Trees. This Sort will grow to the Height of twelve or fourteen Feet, and may be trained up with a regular Stem; ſo that it deſerves a Place in every curious Green-houſe; for their thick ſhining ever-green Leaves make a pleaſing Variety amongſt other hardy exotic Plants.

FRAXINELLA, [is ſo call'd of *Fraxinus*, Lat. *the Aſh-tree*; becauſe its Leaves reſemble thoſe of the *Aſh-tree*, q. d. *the little Aſh*: It is call'd *Dictamnus*; becauſe it has the Smell, Taſte, and Virtues of it] Baſtard, or White Dittany.

The *Characters* are;

It hath a perennial Root: The Leaves are pennated like thoſe of the Aſh: *The Flower conſiſts of many Leaves, and are of an anomalous Figure, four of theſe Petals growing on the Upper-ſide, and one or more on the Under-ſide of the Flower; in the Center of which are produced nine or ten crooked* Stamina *or* Threads: *Each Flower is ſucceeded by many Pods, which are turn'd back like a Rams Horn, and open in two Parts, emitting ſeveral large, hard, black, ſhining Seeds.*

The *Species* are;

1. Fraxinella, *Cluſ.* White Baſtard Dittany; or, Fraxinella, with white Flowers.
2. Fraxinella *purpurea major multiflora. H. R. Par.* Great purple Fraxinella, with many Flowers.
3. Fraxinella *minor purpurea Belgarum. H. R. Par.* Small purple white Dittany of *Holland*.
4. Fraxinella *niveo flore. Cluſ. Hiſt.* White Dittany with Snow-white Flowers.

The firſt two Sorts are propagated either by ſowing their Seeds, or parting the Roots: The latter Method being the moſt expeditious, is generally us'd; tho', if we would ſupply ourſelves with a Quantity of theſe Plants, we muſt procure them from Seeds, for the Roots do not multiply very faſt; nor ſhould they be diſturb'd by parting them oftener than every other Year; for if you part them frequently, or into ſmall Heads, the Flowers will be few in Number, and very weak.

The beſt Seaſon to tranſplant theſe Roots, is towards the latter End of *September*, or Beginning of *October*, that they may be rooted before the hard Froſts begin, by which Means they will be enabled to reſiſt the Cold, and produce much fairer Flowers than thoſe which are tranſplanted in the Spring. The Soil in which theſe Plants thrive beſt, is a freſh, rich, gentle Loam, not too ſtiff, or wet, in both of which they are apt to rot in Winter.

If you would propagate them by Seeds, you muſt ſow them on a Bed of good freſh Earth in an open Expoſure, ſoon after the Seeds are ripe; for if they are kept 'till Spring before they are ſown, they either miſcarry, or lie in the Ground 'till the next Spring before they come up: But you muſt carefully obſerve to weed the Bed; for if you ſuffer the Weeds to root deep in the Ground, they will endanger the drawing of the Seeds out of the Earth, when the former are pull'd up. If the Spring ſhould prove dry when your Plants firſt appear, you ſhould gently water the Bed, and ſhade it with Mats in the Heat of the Day, until the Plants have got Strength, obſerving, as before, to keep them clear from Weeds: In this Bed they may remain until *Michaelmas* following; at which Time you ſhould prepare one or more Beds (according to the Number of your Plants) of the like freſh Earth, into which you muſt plant your Plants at about five or ſix Inches Diſtance each Way, being careful, in taking them out of the Seed-bed, not to break or wound their Roots, as alſo to cloſe the Earth faſt to their Roots, when planted, with your Hands, to prevent their being turn'd out of the Ground by Froſt. In theſe Beds they may remain one Year, by which Time, (if they have thriven well) they will be ſtrong enough to produce Flowers the ſucceeding Year; ſo that now it will be Time to tranſplant them into the Borders of the Flower-Garden where they are deſigned to remain.

The third and fourth Sorts are at preſent more rare in *England*, than the two other Kinds; but of late they have been procured by ſome curious Perſons from abroad. Theſe are as hardy as the other Sorts, and may be propagated in the ſame Manner; and as they produce very beautiful Flowers, ſo they add greatly to the Variety in the Flower-Garden; and requiring but little Care to cultivate them, they deſerve a Place in every good Garden.

FRAXINUS; The Aſh-Tree.

The *Characters* are;

It hath pennated Leaves, which moſtly end in an odd Lobe: The Male Flowers (which grow at a remote Diſtance from the Fruit) have no Petals, but conſiſt of many Stamina: *The Ovary becomes a Seed-veſſel, containing one Seed at the Bottom, which is ſhaped like a Bird's Tongue.*

The *Species* are;

1. FRAXINUS *vulgaris. Park. Theat.* The Common Aſh-Tree.
2. FRAXINUS *vulgaris, foliis ex luteo variegatis.* The ſtriped Aſh.
3. FRAXINUS *folio rotundiore. C. B.* The Manna Aſh.
4. FRAXINUS *florifera botryoides. M. H. R. Blaſ.* The flowering Aſh.
5. FRAXINUS *ex Nova Anglia, pinnis foliorum in mucronem productioribus. Rand. New-England* Aſh, with ſharp-pointed Leaves.
6. FRAXINUS *Caroliniana, latiori fructu. Rand. Carolina* Aſh, with broad Keys.

The firſt Sort is a common Timber-Tree in every Part of *England.*

The ſecond is a Variety of the firſt, from which it only differs in having its Leaves beautifully ſtriped with Yellow.

The third Sort is ſuppoſed to be the Tree from whence the true *Calabrian* Manna is taken.

The fourth Sort was rais'd from Seeds by Dr. *Uvedale* at *Enfield*, which were brought from *Italy* by the late curious Botaniſt Dr. *William Sherrard*, who ſuppos'd this was different from Dr. *Moriſon*'s Tree. But by the Specimens now in Poſſeſſion of that worthy Encourager of Botanical Studies, Sir *Hans Sloane*, Bart. it appears to be the very ſame; notwithſtanding Mr. *Ray* ſuppoſes Dr. *Moriſon*'s Tree to be of *American* Growth.

The fifth and ſixth Sorts were both rais'd from Seeds which came from *America*, but are both of them very hardy. All theſe Kinds may be propagated by Budding them into the common *Aſh*, upon which they will all take very well, and become hardier than upon their own Stock.

The common *Aſh* is propagated by ſowing the Keys, in *October* or *November*, on a Bed of freſh Earth, which ſhould be well dug, and cleans'd from Roots, and noxious Weeds: A ſmall Bed will be ſufficient to raiſe a great Quantity of theſe Trees. The Seeds ſhould be ſown pretty thick, and cover'd about half an Inch thick with Earth.

Theſe Seeds, many times, continue until the ſecond Spring before they come up; you ſhould therefore let the Bed remain undiſturb'd, and keep it clean from Weeds. When your Plants come up, you muſt alſo keep them very clear from Weeds; and if the Seaſon ſhould prove very dry, if you give them now and then a little Water, it will greatly promote their Growth: In this Bed they ſhould remain no longer than the Autumn following, provided they have grown well; at which Time you ſhould prepare a Nurſery, which ſhould be well dug, and clear'd, as before; then with your Spade looſen the Roots of the Plants before you draw them up, otherwiſe you will endanger the breaking of them. When you have drawn them out of the Ground, ſhorten the down-right Tap-root; but do not cut off any of the lateral Fibres: Then having prepared your Ground, plant them in Rows, three Feet Diſtance Row from Row, and a Foot aſunder in the Rows, cloſing the Earth to their Roots with your Feet. In this Nurſery they may remain three or four Years, obſerving to keep them clear from Weeds, as alſo to trim up the Side-branches every Winter, and dig the Ground between the Rows; after which Time you may remove them where they are to remain for good.

This Tree will grow upon almoſt any Soil; but the better the Soil is, the more the Tree will increaſe in Bulk. Notwithſtanding which, it ſhould not by any means be planted too near to other Trees or Plants; for it will exhauſt all the Goodneſs of the Soil from them; and the Shade of this Tree is malignant to moſt other Plants. The Diſtance they ſhould be planted is eight Feet ſquare; and after they have been planted one Year, you may cut down every other Tree, chuſing ſuch of 'em as are crooked, within ſix or eight Inches of the Ground; this will cauſe 'em to make many ſtrong, vigorous Shoots, which, in four or five Years time, will be fit for Arbour-poles, or to make Hoops: And the other remaining ſtrait Trees may be ſuffered to grow for other Timber; the Number of which Trees may be leſſen'd as they increaſe in Bulk, leaving ſtill the moſt promiſing ones to grow for larger Timber.

If a Wood of theſe Trees is rightly manag'd, it will turn greatly to the Advantage of its Owner; for by the Underwood, which will be fit to cut every five or ſix Years for the Uſes above-mentioned, there will be a continual Income more than ſufficient to pay the Rent of the Ground, and all other Charges, and ſtill there will be a Stock preſerv'd for Timber, which, in a few Years, will be worth forty or fifty Shillings *per* Tree.

This Timber is of excellent Uſe to the *Wheelright* and *Cartright* for *Ploughs*, *Axletrees*, *Wheel-rings*, *Harrows*, *Bulls*, *Oars*, *Blocks* for *Pullies*, and many other Purpoſes.

The beſt Seaſon for Felling of theſe Trees is from *November* to *February*; for if it be done either too early in Autumn, or too late in the Spring, the Timber will be ſubject to be infeſted with Worms, and other Inſects: But for Lopping of *Pollards*, the Spring is preferable for all ſoft Woods.

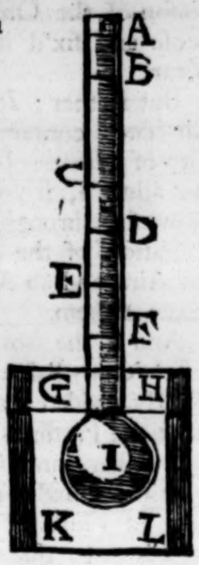
FREEZING, is the fixing of a Fluid, or the depriving it of its natural Mobility by the Action of *Cold*; or it is the Act of converting a *fluid* Subſtance into a *firm*, *coherent*, *rigid* one, call'd *Ice*.

The principal Phænomena of *Freezing*, are;

1ſt: That Water being dilated or rarefied, and all Fluids, *Oil* excepted, *i. e.* in *freezing*, take up more Space, and are ſpecifically lighter than they were before.

That the Bulk and Dimenſions of Water are increas'd by *Freezing*, is found by many Experiments: And it may not be improper here to take notice of the Proceſs of Nature.

A Glaſs Veſſel then, I A, full of Water to A, being immerg'd in a Veſſel of Water mix'd with Salt G H K L, the Water preſently riſes from D to C; which ſeems owing to the ſudden Conſtruction of the Veſſel, haſtily plung'd into ſo cold a Medium: Soon after, from the Point C, it continually deſcends condenſing, 'till it arrives at the Point F; where, for ſome time, it ſeems to remain at reſt: But it ſoon recovers itſelf, and begins to expand, riſing from F to E, and from thence ſoon after, by one violent Leap, mounts to B; and here the Water in I is immediately ſeen all thick and cloudy, and in the very Inſtant of this Leap, is converted into Ice. Add, that while the Ice is growing harder, and ſome of the Water near the Neck of the Veſſel I is *freezing*, the Flux of the Water is continu'd above B towards A, and at length runs out at the Veſſel.



2dly: That they loſe not only of the ſpecifick, but alſo of their abſolute Gravity, by *freezing*; ſo that when they are thaw'd again, they are found conſiderably heavier than before.

3dly: That *frozen* Water is not quite ſo tranſparent as when it was liquid; and that Bodies don't perſpire ſo freely through it.

4thly: That Water, when frozen, evaporates almoſt as much as when fluid.

5thly: That Water does not freeze *in Vacuo*, but requires the Preſence and Contiguity of Air.

6thly: That Water which has been boil'd, does not freeze ſo readily as that which has not.

7thly: That Water being cover'd over with a Surface of Oil of Olives, does not freeze ſo readily as it does without it; and that Nut-oil abſolutely preſerves it under a ſtrong Froſt, when Olive-oil will not.

8thly: That Spirit of Wine, Nut-oil, and Oil of Turpentine, do not freeze at all.

9thly: That the Surface of the Water, in *freezing*, appears all wrinkled; the Wrinkles being ſometimes in parallel Lines, and ſometimes like Rays proceeding from a Centre to the Circumference.

The Theories of *freezing*, or the Method of accounting for theſe *Phænomena*, are very many.

The chief Principles that different Authors have gone upon, are either, that ſome foreign Matter is introduced within the Pores of the Fluid, by Means of which it is fixed, its Bulk increaſed, *&c.*

Or that ſome Mater which was naturally contain'd in the Fluid, is now expell'd; by reaſon of the Abſence of which, the Body becomes fluid, *&c.*

Or that there is ſome Alteration produc'd in the Texture or Form, either of the Particles of the Fluid itſelf, or of ſomething that is contain'd within it.

To ſome one of theſe Principles all the Syſtems of *freezing* are reducible.

The *Carteſians* explicate *freezing* by the Receſs or going out of the Ethereal Matter from the Pores of the Water, or other Liquor; which being once done, the finer Parts are too ſmall and flexible to keep the long, ſlender, and Eel like Particles of Water fluent, or in the Form of a Liquor.

But the *Corpuſcularians*, or *Gaſſendiſts*, aſcribe the *freezing* of Water, with more Probability, to the Ingreſs of Multitudes of cold or frigorifick Particles, as they call 'em; which entring the Liquor in Streams, and diſperſing themſelves every way through it, do croud into the Pores of the Water, and hinder the wonted Agitation of its Parts, and wedge it up, as it were, into the hard or conſiſtent Body of Ice; and from hence proceeds its Increaſe of Dimenſions, Coldneſs, *&c.*

That Ice is ſpecifically lighter than the Water out of which it is by *freezing* made, is certain by its ſwimming in it; and that this Lightneſs of Ice proceeds from thoſe numerous Bubbles which are produced in it by its Congelation, is equally plain: But how thoſe Bubbles come to be generated in *freezing*, and what Subſtance they contain in them, if they are not quite empty, is an Inquiry of great Importance; and, perhaps, if diſcovered, may contribute much to the underſtanding the Nature of Gold.

Mr. *Hobbs* will have it common Air, which intruding into the Water in Congelation, intangles itſelf with the Particles of the Fluid, prevents their Motion, and produces thoſe numerous Bubbles, thus expanding its Bulk, and rendering it ſpecifically lighter.

But, in anſwer to this, no ſuch Ingreſs of Air into Water appears in its Coagulation; and that it does not get into frozen Oil, is plain, becauſe that Body is condens'd by being frozen.

And Mr. *Boyle* has alſo ſhewn, by undoubted Experiments, that Water will freeze in Veſſels hermetically ſealed, and in braſs Bodies or Veſſels cloſely ſtop'd, and into which the Air can have no Ingreſs, hath yet been turn'd into Ice, abounding with theſe Bubbles as numerous as thoſe frozen into the open Air.

He alſo has prov'd by Experiment, that Water kept a while in the exhauſted Receiver, 'till all its Bubbles were emerg'd and gone, being afterwards turn'd into Ice by a *freezing* Mixture, the Ice had ſcarce any Bubbles in it: Whence it is plain, that theſe Bubbles are fill'd with ſome Matter which is within the Water, if they are fill'd with any thing: But he proves alſo, by plain Experiments, that they have none, or exceedingly little true elaſtick Air contained in them.

Others, and thoſe of the greateſt Number, are of Opinion, that the *freezing* Matter is a Salt; and they argue, that an Exceſs of Cold will render Water torpid, but never congeal it without Salt: They ſay, that thoſe Particles that are the chief Cauſe of *freezing*, are ſaline, mix'd in a due Proportion; Congelation bearing a near Relation to Cryſtallization.

This Salt is ſuppoſed to be of the nitrous Kind, and to be furniſh'd by the Air, which is generally found to abound in Nitre.

It is indeed no difficult Matter to account for the Particles of Nitre preventing the Fluidity of Water. Theſe Particles are ſuppos'd to be ſo many rigid pointed *Spicula*, which are eaſily impell'd, or driven into the *Stamina* or Globules of Water; which, by this Means, becoming variouſly mingled and intangled with it, do, by degrees, weaken and deſtroy the Motion of it.

The Reaſon that this Effect ariſes only in ſevere Winter Weather, is, that it is then only that the retracting Action of the nitrous *Spicula* is more than equal to the Power or Principle by which the Fluid is otherwiſe kept in Motion, or diſpos'd for Motion.

Several Experiments of artificial *freezing* ſupport this Opinion.

For if you mix a Quantity of common Saltpetre with Snow, or Ice pulveriz'd, and diſſolve the Mixture in the Fire, and then immerge a Tub full of Water in the Solution; the Water, that Part of it next the Mixture, will freeze preſently, even in a warm Air.

Whence they argue, that the *Spicula* of the Salt is driven through the Pores of the Glaſs, and mix'd with the Water, by the Gravity of the Mixture, and of the incumbent Air: For that it is evident that the Salt has this Effect, inaſmuch as it is certainly known, that the Particles of Water cannot find their Way through the Pores of the Glaſs.

In theſe artificial *freezings*, in whatever Part the Mixture is apply'd, there is preſently a Skin or *Lamma* of Ice produc'd, whether at the Top, Bottom, or Sides; by reaſon that there is always a Stock of ſaline Corpuſcles ſufficient to overpower theſe Particles of Fire, but *natural Congelations* are confin'd to the Top of the Water, where the laſt moſt abounds.

But this Syſtem is oppos'd by the Author of the *Nouvelle Conjecture pour expliquer la Nature de la Glace*, who objects, that it does not appear that Nitre always enters the Compoſition of Ice; but if it did, it would fall ſhort of accounting for ſome of the principal Effects; as,

How ſhould the Particles of Nitre, by entering the Pores of the Water, and fixing the Parts, cauſe the Water to dilate, and render it ſpecifically lighter? They ſhould naturally augment its Weight.

This, and ſome other Difficulties, ſhew the Neceſſity of a new Theory; and therefore the ingenious Author advances this which follows, which ſeems to ſolve the *Phænomena* in a Manner that is more eaſy and ſimple, as not depending upon the Admiſſion or Extruſion of any heterogeneous Matter.

That Water freezes in the Winter only; becauſe its Parts then being more cloſely join'd together, do mutually imbaraſs one another, and loſe all the Motion they had; and that the Air, or rather an Alteration in the Spring and Force of the Air, is the Cauſe of this cloſer Union of Water.

It is evident from Experiment, that there are an infinite Number of Particles of groſs Air interſpers'd among the Globules of Water; and it is allow'd, that each Particle of Air has the Virtue of a Spring: And hence this Author argues, that the ſmall Springs of groſs Air mixed with Water, have more Force in cold Winter Weather, and do then unbend themſelves more than at other Times. Hence thoſe Springs thus unbending themſelves on one Side, and the external Air continuing to preſs the Surface of the Water on the other, the Particles of the Water being thus conſtringed and lock'd up together, muſt loſe their Motion and Fluidity, and form a hard, conſiſtent Body, 'till a Relaxation of the Spring of the Air, from an Increaſe of Heat, reduce the Particles to their old Dimenſions, and leave Room for the Globules to flow again.

But this Syſtem ſeems to be built upon a falſe Principle; for the Spring or Elaſticity of the Air is not increas'd by Cold, but diminiſh'd: Air condenſes by Cold, and expands itſelf by Heat; and it is demonſtrable in Pneumaticks, that the elaſtick Force of expanded Air is of that to the ſame Air as condens'd, as the Bulk when rarefied is to its Bulk when condens'd.

Indeed, ſome Authors, in order to account for the Increaſe of the Bulk and Dimenſion of the ſpecifick Gravity of frozen Water, have advanc'd as follows; *viz.* That the aqueous Particles, in their natural State, were nearly Cubes, and ſo fill'd their Space without the Interpoſition of many Pores; but that they are chang'd from Cubes to Spheres, by Congelation: From whence it will neceſſarily follow, that there muſt be a great deal of empty Space between them.

But, in Oppoſition to this Hypotheſis, the Nature of Fluidity and Firmneſs eaſily ſuggeſts, that ſpherical Particles are much properer to conſtitute a Fluid than cubical ones, and leſs diſpos'd to form a fix'd than cubick one.

But, after all, in order to come at a conſiſtent Theory of *Freezing*, we muſt either have Recourſe to the frigorifick Matter of the *Corpuſcularians*, conſidered under the new Light and Advantages of the *Newtonian* Philoſophy, or to the Ethereal Matter of the *Carteſians*, under the Improvements of Monſ. *Gauteron*.

The true Cauſe of *Freezing*, or the Congelation of Water into Ice, ſay the former, ſeems plainly to be the Introduction of the frigorifick Particles into the Pores or Interſtices between the Particles of the Water, and by that Means getting ſo near them, as to be juſt within the Spheres of one another's *attracting Force*, and then they muſt cohere into one ſolid or firm Body: But Heat afterwards ſeparating them, and putting them into various Motions, breaks this Union, and ſeparates the Particles ſo far from one another, that they get out of the Diſtance of the *attracting Force*, and into the Verge of the *repelling Force*, and then the Water reaſſumes its fluid Form.

Now that *Cold* and *Freezing* do proceed from ſome Subſtance of a ſaline Nature floating in the Air, it ſeems probable from hence;

That all *Salts*, and more eminently ſome particular ones, do prodigiouſly increaſe the Force and Effects of *Cold*, when mix'd with *Snow* or *Ice*. It is alſo evident, that all ſaline Bodies do produce a Stiffneſs and Rigidity in the Parts of thoſe Bodies into which they enter.

It appears, by microſcopical Obſervations upon *Salts*, that the Figure of ſome *Salts*, before they ſhoot into Maſſes, are thin, double-wedg'd, like Particles which have abundance of Surface, in reſpect to their Solidity; and is the Reaſon why they ſwim in Water, when once rais'd in it, tho' ſpecifically heavier.

Theſe ſmall Points getting into the Pores of the Water, whereby they are alſo, in ſome meaſure, ſuſpended in the Winter-time, when the Heat of the Sun is not ordinarily ſtrong enough to diſſolve the Salts into a Fluid, to break their Points, and to keep them in perpetual Motion; being leſs diſturb'd, are at more liberty to approach one another; and, by ſhooting into Cryſtals of the Form above-mention'd, do, by both their Extremities, inſinuate themſelves into the Pores of the Water, and by that Means freeze it into a ſolid Form. And it is apparent, that the Dimenſions of Water are increas'd by *freezing*, the Particles of it being kept at ſome Diſtance from one another by the Intervention of the frigorifick Matter.

But beſides this, there are many little Volumes, or ſmall Particles of Air, included at ſeveral Diſtances, both in the Pores of the watery Particles, and in the Interſtices form'd by their ſpherical Figure. Now, by the Inſinuation of the Cryſtals, the Volumes of Air are driven out of the watery Particles, and many of them uniting, from larger Volumes, which thereby have a greater Force to expand themſelves than when they are diſpers'd; and ſo both enlarge the Dimenſions, and leſſen the ſpecifick Gravity of Water thus congeal'd into Ice.

And hence (ſays Dr. *Cheyne*, from whom this laſt Account is taken) we may gueſs at the Manner how Water impregnated with Salts, Sulphurs, or Earths, which are not eaſily diſſolvable, may Form itſelf into Metals, Minerals, Gums, and other Foſſils; the Parts of theſe Mixtures becoming a Cement to the Particles of Water, or getting into their Pores, change them into theſe different Subſtances.

For the *ſecond*: As an Ethereal Matter or Medium is generally allow'd to be the Cauſe of the Motion of Fluids; and as the Air itſelf has all its Motion from the ſame Principle; it follows, that all Fluids muſt remain in a State of Reſt or Fixity, when that Matter loſes of its neceſſary Force. And conſequently, the Air being leſs warm'd in the Winter-time, by reaſon of the Obliquity of the Sun's Rays, the Air is more denſe and fix'd in Winter than any other Seaſon of the Year.

But farther: It is evident from divers Experiments, that the Air does contain a Salt which is ſuppos'd to be of the Nature of Nitre. If this be granted, and the Denſity of the Air allow'd, it will follow, that the Particles of this Nitre muſt likewiſe be brought nearer together, and thicken'd by the Condenſation of the Air: As, on the contrary, a Rarefaction of the Air, and an Augmentation of its Fluidity, muſt divide and ſeparate them.

And if the ſame happens to all Liquors that have imbib'd or diſſolv'd any Salt; if the Warmth of the Liquid kept the Salt exactly divided; and if the Coolneſs of a Cellar, or of Ice, cauſe the Particles of the diſſolv'd Salt to approach, run into each other, and ſhoot into Cryſtals; Why ſhould the *Air*, which is allow'd to be a Fluid, be exempt from the general Law of Fluids?

'Tis true, that the Nitre of the Air being groſſer in cold Weather than in hot, muſt have a leſs Velocity; but ſtill the Product of its augmented Maſs into the Velocity that remains, will give it a greater *Momentum* or Quantity of Motion. Nor is there any thing farther requir'd to make this Salt act with greater Force againſt the Parts of Fluids; and this may probably be the Cauſe of the great Evaporation in froſty Weather.

This aereal Nitre muſt neceſſarily promote the Concretion of Liquids; for it is not the Air, nor yet the Nitre that it contains, which gives the Motion to Fluids; 'tis the Ethereal Medium: Therefore a Diminution of the Motion of Reſt ariſes from the Diminution of that Force.

Now the Ethereal Matter, which in the Winter-time is weak enough, muſt ſtill loſe more of its Force by its Action againſt Air condens'd, and loaded with large Particles of Salt. It muſt therefore loſe of its Force in cold Weather, and become leſs diſpos'd to maintain the Motion of the Fluids.

In fine: The Air, during Froſt, may be eſteem'd like the Ice impregnated with Salt wherewith Liquors are iced in Summer-time. It is very probable that theſe Liquors *freeze* by reaſon of a Diminution of the Motion of the Ethereal Medium, by its acting againſt the Ice and Salt together; and the Air is not liable to prevent its Concretion by all its ſcorching Heat.

The Air (ſays Mr. *Boyle*) being a Fluid as well as Water, and impregnated with Salts of different Kinds, 'tis not improbable, that what happens in Water impregnated with ſuch Salts, may alſo happen in the Air. Two proper Quantities of different Salts being diſſolv'd in hot Water, they floated undiſtinguiſhably in it, and retain'd a Capacity to act in Conjunction upon ſeveral Occaſions; yet when the Liquor becomes cold, the ſaline Particles of one Kind being no longer agitated by a due Degree of Heat, ſhot into Cryſtals, and loſing their Fluidity and Motion, viſibly ſeparated themſelves from the other, which ſtill continu'd fluid in the Liquor, and capable of acting ſeparately.

We have divers Accounts in the *Philoſophical Tranſactions*, of a *freezing Rain* which fell in the Weſt of *England* in *December* 1672. This Rain, as ſoon as it touch'd any thing above the Ground, as a Bough, or the like, immediately ſettled into Ice, and by multiplying and enlarging, the Iſicles broke all down with its Weight; the Rain that fell on the Snow immediately froze into Ice, without ſinking into the Snow at all.

It made an incredible Deſtruction of Trees beyond any thing in all Hiſtory. A certain Gentleman weigh'd a Sprig of an *Aſh-tree* of juſt three Quarters of a Pound: The Ice which was on it, weigh'd 16 Pounds: That ſome Perſons were frighted with the Noiſe in the Air, 'till they underſtood that it was the Clatter of Icy Boughs daſh'd againſt each other.

Dr. *Beale* obſerves, that there was no conſiderable Froſt obſerv'd on the Ground during the whole time; whence he concludes, that a Froſt may be very fierce and dangerous on the Tops of ſome Hills and Plains; while in other Places it keeps at two, three, or four Feet Diſtance above the Ground, Rivers, Lakes, *&c.* and may wander about very furious in ſome Places, and remiſs in others not far off. The Froſt was followed by glowing Heats, and a wonderful Forwardneſs of Flowers and Fruits.

FRITILLARIA; Fritillary or Chequer'd Tulip.

The *Characters* are;

The Flower conſiſts of ſix Leaves, and is of the Bell-ſhap'd Lily *Flowers, pendulous, naked, and for the moſt part chequer'd:*

quer'd: The Style of the Flower becomes an oblong Fruit, which is divided into three Cells, and fill'd with flat Seeds, lying in a double Row: The Root conſiſts of two fleſhy Knobs, which are for the moſt part ſemi-globular, betwixt which ariſes the Flower-ſtalk.

The *Species* are;

1. **Fritillaria** *ſerotina, floribus ex flavo virentibus. C. B.* The late flowering Fritillary, with greeniſh yellow Flowers, *commonly call'd*, the Leather Coat, or Common Fritillary.

2. **Fritillaria** *alba præcox. C. B.* The early white Fritillary.

3. **Fritillaria** *alba variegata. C. B.* The white chequer'd Fritillary.

4. **Fritillaria** *ſerotina, floribus ex flavo-virentibus, major. Boerh. Ind.* The great late flowering Fritillary, with a greeniſh yellow Flower; or the Common Fritillary, by ſome call'd Snake's-head Iris.

5. **Fritillaria** *flavo flore. Cluſ.* The yellow Fritillary.

6. **Fritillaria** *præcox purpureo-variegata. C. B.* Early purple variegated Fritillary.

7. **Fritillaria** *folio ſplendente, flore majore, ex viridi & purpura variegato, ſplendente. Boerh. Ind.* Shining-leav'd Fritillary, with a large green and purple-ſhining variegated Flower, *commonly call'd* the Monſter.

8. **Fritillaria** *umbellifera. C. B.* Many-leav'd Fritillary.

9. **Fritillaria** *lutea maxima Italica. Park. Par.* Greateſt yellow *Italian* Fritillary.

10. **Fritillaria** *ſerotina, floribus ex flavo-virentibus, flore pleno. H. R. Par.* Late Fritillary, with double greeniſh yellow Flowers.

11. **Fritillaria** *nigra. Lob. Adv.* Black Fritillary.

12. **Fritillaria** *flore ex rubro-purpureo & viridi variegato. Boerh. Ind.* Fritillary with a reddiſh purple Flower ſtrip'd with Green.

13. **Fritillaria** *flore ex pallide-viridi & viete purpureo variegato. Boerh. Ind.* Fritillary with a pale green Flower, variegated with a deep purple.

14. **Fritillaria** *Iſabella dicta, floribus ex pallide rubicundo virentibus. H. L.* Iſabella Fritillary, with a pale red greeniſh Flower.

15. **Fritillaria** *maxima, flore obſoletæ purpuræ. Tourn.* The greateſt Fritillary, of a worn-out purple Colour, *commonly call'd* the Perſian Lily.

16 **Fritillaria** *minima. Swert. Flor.* The leaſt Fritillary, or ſmall Perſian Lily.

17. **Fritillaria** *lutea, folio Polygonati, fructu breviori. Boerh. Ind.* Yellow Fritillary, with a Leaf like Solomon's Seal, and a ſhort Fruit.

There are ſeveral other Varieties of this Flower, which are propagated in curious Flower-Gardens abroad, (eſpecially in *Holland*) which differ in the Colour or Size of their Flowers; but as theſe are only Varieties which were obtain'd from Seeds, ſo it would be needleſs to mention them in this Place, ſince there will be new Varieties obtain'd every Year where Perſons are curious in ſowing their Seeds.

Theſe Plants are propagated either by Seeds, or Off-ſets from the old Roots: By the firſt of which Methods new Flowers will be obtain'd, as alſo a larger Stock of Roots in three Years, than can be obtain'd in twenty or thirty Years by the latter Method: I ſhall therefore treat firſt of their Propagation by Seeds.

Having provided yourſelf with ſome good Seeds, ſav'd from the faireſt Flowers, you muſt procure ſome ſhallow Pans or Boxes, which muſt have ſome Holes in their Bottoms to let out the Moiſture: Theſe you ſhould fill with light freſh Earth, laying a few Potſheards over the Holes, to prevent the Earth from ſtopping them; then having laid the Earth very level in the Boxes, &c. you muſt ſow the Seeds thereon pretty thick, covering it with fine ſifted Earth a Quarter of an Inch thick. The Time for ſowing the Seed is about the Beginning of *Auguſt*; for if it be kept much longer out of the Ground, it will not grow; then place the Boxes or Pans where they may have the Morning Sun until 11 o'Clock, obſerving, if the Seaſon proves dry, to water them gently, as alſo to pull up all Weeds ſo ſoon as they appear; for if they are ſuffer'd to remain until they have taken deep Root into the Earth, they would draw the Seeds out of the Ground whenever they are pull'd up. Toward the latter End of *September* you ſhould remove the Boxes, &c. into a warmer Situation, placing them under a Hedge or Wall expos'd to the South; in which Place they may remain until the Middle of *March*, by which Time the Plants will be come up an Inch high: you muſt therefore remove the Boxes as the Weather increaſes hot, into a more ſhady Situation; for while the Plants are young, they are liable to ſuffer by being too much expos'd to the Sun: And in this ſhady Situation they may remain during the Heat of the Summer, obſerving to keep them clear from Weeds, and to refreſh them now and then with a little Moiſture; but be careful not to give them much Water after their Leaves are decay'd, which would rot the Roots. About the Beginning of *Auguſt*, if the Roots are very thick in the Boxes, you ſhould prepare a Bed of good light freſh Earth, which muſt be levell'd very even, upon which you ſhould ſpread the Earth in the Boxes in which the ſmall Roots are contain'd, equally covering it about one fourth of an Inch thick with the ſame freſh Earth: This Bed ſhould be ſituated in a warm Poſition, but not too cloſe to Hedges, Walls, or Pales, which would cauſe their Leaves to be long and ſlender, and make the Roots weaker than if placed in a more open Expoſure.

In this Bed they may remain until they flower, which is generally the third Year from ſowing; at which Time you ſhould put down a Mark to the Roots of all ſuch as produce fair Flowers; and at the Time of taking them out of the Ground (which ought to be ſoon after their green Leaves are decay'd) they may be ſelected into a Bed amongſt your old Roots of this Flower, which for their Beauty are preſerv'd in the beſt Gardens; but the other leſs valuable Flowers may be planted in the Borders of the Parterre Garden for their Variety, where being intermix'd with other Flowers of different Seaſons, they will make a good Appearance.

The fine Sorts of this Flower ſhould remain undiſturb'd three Years, by which Time they will have produc'd many Off-ſets, and ſhould be therefore taken up when their Leaves are decay'd, and planted into a freſh Bed, taking ſuch of their Off-ſets as are large enough to produce Flowers to plant in the Flower-Garden, but the ſmaller Roots may be planted into a Nurſery-bed until they have obtain'd Strength enough to flower; but you muſt never ſuffer theſe Roots to lie out of the Ground when you remove them, but plant them again immediately, for otherwiſe they will periſh.

During theſe three Years which I have adviſ'd the Roots to remain in the Beds, the Surface of the Earth ſhould be ſtirr'd every Autumn with a Trowel, obſerving not to go ſo deep as to bruiſe the Root, and at the ſame Time lay a thin Cover of very rotten Dung or Tanner's Bark upon the Surface of the Beds; which being waſh'd into the Ground, will cauſe the Flowers to be larger, as alſo the Roots to make a greater Increaſe: You muſt alſo obſerve to keep them conſtantly clear from Weeds, and thoſe Roots which you would preſerve with Care, ſhould not be ſuffer'd to ſeed.

FRITILLARIA CRASSA. *Vide* Aſclepias.

FRONDOSE, [*frondoſus*, Lat.] *full of*, or *apt to bear Leaves*.

FRONTATED, [*frontatus*, Lat.] a Term us'd by Botaniſts, relating to the Leaf of a Flower, which grows broader and broader, perhaps terminating in a Right Line, and is us'd in Oppoſition to *cuſpidated*, i. e. when the Leaves of a Flower end in a Point.

FROST may be defin'd to be an exceſſive cold State of the Weather, whereby the Motion and Fluidity of the Liquors are ſuſpended; or, it is that State of the Air, &c. whereby Fluids are converted into Ice.

By *Froſt*, Metals contract, or are ſhorten'd. Monſ. *Auzout* found by an Experiment, that an Iron Tube twelve Feet long, upon being expos'd to the Air in a froſty Night, loſt two Lines of its Length. But this may be ſuppos'd to be wholly the Effect of Cold.

On the contrary, *Froſt* does not contract Fluids; but, on the other hand, ſwells or dilates them near one tenth of their Bulk.

Mr. *Boyle* gives us ſeveral Experiments of Veſſels made of Metals exceeding thick and ſtrong, which being fill'd with Water, cloſe ſtopt, and expos'd to the Cold, the Water being expanded by freezing, and not finding either Room or Vent, burſts the Veſſels.

A ſtrong Barrel of a Gun with Water in't, being ſtopt cloſe and frozen, was rent the whole Length: And a ſmall Braſs Veſſel five Inches deep, and two in diameter, fill'd with Water, &c. and frozen, lifted up its Lid, which was preſs'd with a Weight of 56 Pounds.

There are alſo related many remarkable Effects of *Froſt* on Vegetables. *Morery Hiſt. de France*, ſays, That Trees are frequently ſcorch'd and burnt up with *Froſt*, as with the moſt exceſſive Heat, and that even in ſo warm a Climate as *Provence*.

Mr. *Bobart* relates, that in the great *Froſt*, *Anno* 1683, *Oaks*, *Aſh's*, *Walnut-trees*, &c. were miſerably ſplit and cleft, ſo as they might be ſeen thro', and this too with terrible Noiſes like the Exploſion of Fire-Arms: That the Clifts were not only in the Bodies, but continu'd to the larger Boughs, Roots, &c. *Philoſ. Tranſact.* Nº 165.

Mr. *Derham* ſays, That the *Froſt* in 1708 was remarkable throughout the greateſt Part of *Europe*; and the greateſt in Degree, if not the moſt univerſal in the Memory of Man: That it extended throughout *England*, *France*, *Germany*, *Denmark*, *Italy*, &c. but was ſcarce felt in *Scotland* and *Ireland*. All the *Orange-trees* and *Olives* in *Italy*, *Provence*, &c. and all the *Walnut-trees* throughout *France*, with an Infinity of other Trees, periſh'd by the *Froſt*.

Monſ. *Gauteron* ſays, They had a Gangrene on them, which he takes to be the Effect of a corroſive Salt, which corrupted and deſtroy'd their Texture. He adds, That there is ſo much Reſemblance between the Gangrene befalling Plants through *Froſt*, and that which the Parts of Animals are liable to, that they muſt have ſome analogous Cauſe. Corroſive Humours burn the Parts of Animals; and the aerial Nitre condens'd, has the ſame Effects on the Parts of Plants. *Memoires de l'Academie Royale des Sciences*, An. 1709.

Mr. *Derham* ſays, That the greateſt Sufferers in the Animal Kingdom were Birds and Inſects; but Vegetables were much the greateſt Sufferers: That few of the tender Sorts of Vegetables eſcap'd the Severity of the *Froſt*; *Bays*, *Laurels*, *Roſemary*, *Cypreſs*, *Alaternus's*, *Phillyrea's*, *Arbutus's*, *Lauruſtinus's*, and even *Furz*, with moſt of the fruteſcent Herbs, as *Lavenders*, *Abrotanums*, *Rue*, *Thyme*, &c. were generally deſtroy'd. He adds, That the Sap of the finer Wall-fruit was ſo congeal'd and deſtroy'd, that it ſtagnated in the Limbs and Branches, and produc'd Diſorders like to Chilblains in Human Bodies, which would turn to Mortifications in many Parts of the Trees. That the very Buds of the finer Trees, both in the Leaf, Buds, and Bloſſom-Buds, were quite kill'd, and dry'd into a farinaceous Matter.

Mr. *Derham* relates it as a common Obſervation, That Vegetables ſuffer'd more from the *Sun* than from the *Froſt*; in that the Sun-ſhine melting the Snow, and opening the Ground, left it more expos'd to the Rigours of the enſuing Night. It was likewiſe obſerv'd, at a Meeting of the *Royal Society*, That the Calamities which befel Trees, aroſe not purely from their being frozen, but principally from the Winds ſhaking and rocking them when they were frozen, which rent and parted their Fibres. *Philoſoph. Tranſact.* Nº 324.

Hoar-froſt or *White-froſt* is the Dew frozen or congeal'd early in cold Mornings, chiefly in Autumn. This (as Mr. *Regis* obſerves) is an Aſſemblage of little Parcels of Ice or Cryſtals, which are of various Figures, according to the different Diſpoſition of the Vapours which met and condenſed by Cold.

Dew is, to all Appearance, the Matter of *Hoar-froſt*; tho' many of the *Carteſians* ſuppoſe it to be form'd of a Cloud, and either congeal'd in the Cloud, and ſo let fall, or ready to be congeal'd as ſoon as it arrives at the Earth.

In the Year $172\frac{8}{9}$, there was a remarkable *Froſt*, which continued for ſome Months, and deſtroyed a great Number of Trees and Plants in ſeveral Parts of *Europe*; a brief Account of which may not be improper to be here inſerted.

The Autumn began with cold North and Eaſt Winds, and early in *November* the Nights were generally froſty; tho' the Froſt did not enter the Ground deeper than the Sun thaw'd the ſucceeding Days: but towards the End of *November*, the Winds blew extremely cold from the North; which was ſucceeded by a great Snow, which fell in ſuch Quantities in one Night, as to break off large Arms, as alſo the Tops of many ever-green Trees, on which it lodged. After the Snow had fallen, it began to freeze again, the Wind continuing to blow from the North; the Days were dark and cloudy for ſome Time, but afterwards it cleared up, and the Sun appeared almoſt every Day; which melted the Snow where expoſed to it, whereby the Froſt penetrated deeper into the Ground. It was obſervable, that during theſe clear Days, a great Miſt or Vapour appeared in the Evenings, floating near the Surface of the Ground till the Cold of the Night came on, when it was ſuddenly condenſed and diſappeared. About the 8th of *December* the Nights were extremely cold, the Spirits in the *Thermometer* fell 18 Degrees below the freezing Point; and on the 10th of the ſame Month, the Froſt was as ſevere as had been known in the Memory of Man; the Spirits in the *Thermometer* fell to 20 Degrees below the freezing Point. At this Time vaſt Numbers of *Lauruſtinus's*, *Phillyrea's*, *Alaternus's*, *Roſemary*, *Arbutus*, and other ever-green Trees and Shrubs, began to ſuffer; eſpecially ſuch as had been trimmed up to Heads with naked Stems, or had been clipped late in the Autumn. At this Time alſo there were great Numbers of large deciduous Trees diſbarked, by the Froſt; as *Pear-trees*, *Plane-trees*, *Walnut-trees*, with many other Sorts; and it was chiefly on the Weſt and South-weſt Side of the Trees, that the Bark came off.

About the Middle of *December* the Froſt abated of its Intenſeneſs, and ſeemed to be at a Stand, till the 23d of the ſame Month, when the Wind blew extreme ſharp and cold from the Eaſt, and the Froſt increaſed again, continuing very ſharp till the 28th Day, when it began to abate again, and ſeemed to be going off, the Wind changing to the South; but it did not continue long in this Point, before it changed to the Eaſt again, and the Froſt returned, tho' it was not ſo violent as before.

Thus the Weather continued for the moſt part froſty, till the Middle of *March*, with a few Intervals of mild Weather, which brought forward ſome of the early Flowers; but the Cold returning, ſoon deſtroyed them; ſo that thoſe Plants which uſually flower in *January* and *February*, did not this Year appear till *March*; and before they were fully blown, were cut off by the Froſt; of this Number were all the Spring *Crocus's*, *Hepatica's*, *Perſian Iris's*, *Black Hellebore's*, *Mezereon's*, with ſome others.

The *Cauliflower-plants* which were planted out of the Beds into the open Ground, during the Intervals between the Froſt, were moſt of them deſtroyed, or ſo much cut, that they loſt moſt of their Leaves; the early *Beans* and *Peaſe* were moſt of them killed, and many Fruit and Foreſt Trees, which had been lately removed, were quite deſtroyed. The Loſs was very great to ſome curious Perſons, who had been many Years endeavouring to naturalize great Numbers of exotic Trees and Shrubs, abundance of which were either totally killed, or deſtroyed to the Surface of the Ground: Amongſt this Number there were many Sorts deſtroyed, which had endured the open Air many Years, without receiving the leaſt Injury from the Cold; ſuch as *Paſſion-flowers*, *Cork-trees*, *Ciſtus's*, *Roſemary*, *Stœchas*, *Sage*, *Maſtick*, and ſome others. In ſome Places the young *Aſh* and *Walnut-trees* were killed; but when the Froſt went off, there appeared to have been much more Damage done in the Gardens, than there really was; which occaſioned many People to dig up and deſtroy large Quantities of Trees and Shrubs, which they ſuppoſed were killed; whereas thoſe who had more Patience, and ſuffered them to remain, fared better; for great Numbers of them ſhot out again, ſome from their Stems and Branches, and others from their Roots, the following Summer.

Nor was the Froſt more ſevere in *England*, than in other Parts of *Europe*, but on the contrary, in compariſon, favourable; for in the Southern Parts of *France*, the *Olives*, *Myrtles*, *Ciſtus's*, *Alaternus's*, and ſeveral other Trees and Shrubs, which grow there almoſt ſpontaneouſly, were either deſtroyed, or at leaſt were killed to their Roots; and about *Paris*, and the Northern Parts of *France*, the Buds of their Fruit-Trees were deſtroyed, altho' they remained cloſed; ſo that there were very few Bloſſoms which opened that Spring. The *Fig-trees* were in ſeveral Parts of *France* quite killed; and in *England*, their tender Branches were deſtroyed; ſo that there was very little Fruit on thoſe Trees the following Summer, except where they were protected from the Froſt.

In *Holland* the *Pines* and *Firs*, with ſeveral other Trees, which are Natives of cold Countries, were greatly injured by the Cold; and moſt of the Trees and Shrubs, which were brought from *Italy*, *Spain*, or the South Parts of *France*, which had been planted in the full Ground, in that Country, were intirely killed; tho' many other Sorts, which had been brought from *Virginia* and *Carolina*, eſcaped very well in the ſame Gardens. But the Perſon who ſuffered moſt in that Country, was the learned Dr. *Boerhaave*, who had been ſeveral Years endeavouring to naturalize as many exotic Trees and Shrubs as he could poſſibly obtain from the ſeveral Parts of the World; great Numbers of which were intirely deſtroyed by the Froſt this Winter.

In ſome Parts of *Scotland* they not only loſt many of their curious Flowers, Plants, and Trees; but great Numbers of Sheep and other Cattle were buried under the Snow, where they periſhed; and many poor People, who went to look after their Cattle, were equal Sufferers with them, being buried in the Snow, which in ſome Places fell eight or nine Feet deep in one Night.

It has been obſerved by *Thermometers*, when that Kind of hovering lambent Fog ariſes, (either Mornings or Evenings) which frequently betokens fair Weather, that the Air, which in the preceding Day was much warmer, has upon the Abſence of the Sun become many Degrees cooler than the Surface of the Earth; which being near 1500 Times denſer than the Air, cannot be ſo ſoon affected with the Alternacies of Heat and

Cold; whence 'tis probable, that thoſe Vapours which are raiſed by the Warmth of the Earth, are by the cooler Air ſoon condenſed into a viſible Form. The ſame Difference has been obſerved between the Coolneſs of the Air, and the Warmth of Water in a Pond, by putting a *Thermometer*, which hung all Night in the open Air in Summer-Time, into the Water, juſt before the riſing of the Sun, when the like Reek or Fog was riſing on the Surface of the Water.

FRUCTIFEROUS, [*fructifer*, Lat.] *Fruit-bearing*, *fruitful.*

FRUCTUS. *Vide* Fruit.

FRUIT is the Production of a Tree or Plant, for the Propagation or Multiplication of its Kind: In which Senſe *Fruit* includes all Kinds of *Seeds*, with their Furniture, *&c.* Botaniſts uſe it to ſignify, properly, that Part of a Plant wherein the Seed is contain'd, which the *Latins* call *Fructus*, and the *Greeks* Καρπὸς.

The Fruit of ſome Plants are produced ſingly, as are their Flowers, and ſometimes they are produced in Cluſters, as in moſt Fruit-Trees, which are alſo fleſhy; but in many Plants they are dry.

The Word *Fruit* is alſo us'd to ſignify an Aſſemblage of Seeds in a Plant, as in a *Pea*, *Bean*, *Ranunculus*, &c. and in its general Signification, for all Kinds of Grain, whether naked or inclos'd in Cover, *Capſula*, or Pod, whether bony, fleſhy, ſkinny, membraneous, or the like.

Fruit is the Product or Reſult of the Flower; or that for whoſe Production, Nutrition, *&c.* the Flower is intended.

The Structure and Parts of different *Fruits* are different in ſome Things; but in all the Species, the eſſential Parts of the *Fruit* appear to be only Continuations or Expanſions of thoſe which are ſeen in the other Parts of the Tree.

Dr. *Beale* ſuggeſts ſome very good Reaſons for a direct Communication between the remoteſt Parts of the *Tree* and the *Fruit*; ſo that the ſame Fibres or *Stamina* which conſtitute the Root, Trunk, and Boughs, are extended into the very *Fruit.*

Thus, if you cut open an Apple tranſverſely, you will find it to conſiſt chiefly of four Parts: *viz.* 1. a *Skin*, or Cortex, which is only a Production of the Skin or outer Bark of the Tree; 2. a *Parenchyma* or Pulp, which is an Expanſion and Intumeſcence of the *Ble* or inner Bark of the Tree; 3. the Fibres or Ramifications of the woody Part of the Tree; 4. the Core, which is the Produce of the Pith or *Medulla* of the Plant, indurated or ſtrengthen'd by Twigs of the Wood and Fibres inoſculated therewith: This ſerves to furniſh a Cell or Lodge for the Kernels, filtrates the Juice of the *Parenchyma*, and conveys it, thus prepar'd, to the Kernel.

Of the Fibres, Authors generally reckon fifteen Branches; of which, ten penetrate the *Parenchyma*, and incline to the Baſis of the Flower; the other five aſcend more particularly from the *Pedicle* or Stalk, and meet with the former at the Baſe of the Flower; to which Branches the *Capſulæ* or Coats of the Kernels are faſten'd.

Theſe Branches being firſt extended thro' the *Parenchyma* to the Flower, furniſh the neceſſary Matter for the Vegetation of it: But as the Fruit increaſes, it intercepts the Aliment; and thus the Flower is ſtarv'd and falls off.

In a *Pear* there are five Parts to be diſtinguiſh'd, *viz.* the *Skin*, *Parenchyma*, *Ramification*, *Stone*, and *Acetarium.*

The three firſt Parts are common to the *Apple.* The Stone, obſerv'd chiefly in *Choke-Pears*, is a Congeries of ſtrong Corpuſcles, that are diſpers'd throughout the whole *Parenchyma*, but in the greateſt Plenty, and cloſeſt together about the Center or *Acetarium*: It is form'd of the ſtony or calculous Part of the nutritious Juice.

The *Acetarium* is a Subſtance of a tart, acid Taſte, of a globular Figure, inclos'd in an Aſſemblage of ſeveral of the ſtony Parts before-mention'd.

In a *Plum*, *Cherry*, &c. there are four Parts, *viz.* a *Coat*, *Parenchyma*, *Ramification*, and *Nucleus* or *Stone.* The *Stone* conſiſts of two very different Parts: The external or harder Part, call'd the *Stone* or *Shell*, is a Concretion of the ſtony or calculous Parts of the nutritious Juice, like the Stone in Pears, within it. The Inner, call'd the *Kernel*, is ſoft, tender, and light, being deriv'd from the Pith or *Medulla* of the Tree by Seminal Branches, which penetrate the Baſe of the Stone.

The *Nut* or *Acorn* conſiſts of a *Shell*, *Cortex*, and *Medulla*: The *Shell* conſiſts of a Coat and *Parenchyma*, deriv'd from the Bark and Wood of a Tree.

The *Cortex* conſiſts of an inner and outer Part: The firſt is a Duplicature of the inner Tunick of the Shell: The ſecond is a Moſſy Subſtance, deriv'd from the ſame Source as the *Parenchyma* of the Shell. But Authors are not agreed, whether the *Medulla* or Pulp of the Kernel does ariſe from the Pith of the Tree, or the cortical Part thereof.

Berries, as *Grapes*, &c. contain (beſides three general Parts, *viz. Coat*, *Parenchyma*, and *Ramification*) Grains of a ſtony Nature, to do the Offices of Seeds.

Fruits in general are ſerviceable in guarding, preſerving, and feeding the inclos'd Seed; in filtrating the coarſer, more earthy, and ſtrong Parts of the nutritious Juice of the Plant, and retaining it to themſelves; ſending none but the moſt pure, elaborated, and ſpirituous Parts to the Seed, for the Support and Growth of the tender, delicate Embryo, or Plantule, which is therein contained.

FRUMENTACEOUS, [*Frumentaceus*, Lat.] a Term apply'd by *Botaniſts* to all ſuch Plants as have a Conformity with Wheat, (call'd in Latin, *Frumentum*) in reſpect either of their Fruits, Leaves, Ears, or the like.

FRUMENTUM INDICUM. *Vide* Mays.

FRUTEX, a Shrub, a Vegetable of a Genus between a Tree and an Herb, but of a woody Subſtance.

FRUTEX *Africanus*, *Ambram Spirans. Volk.* The Amber-Tree, *vulgo.*

This Shrub has, by no Botanick Writers, been reduced to any proper Claſs; ſo I have taken the Liberty of continuing it under its former looſe Name, having never yet ſeen the Fruit; tho', by the Flower, I imagine it will be a Congener to the *Gallium*, or *Ladies Bedſtraw*: But I ſhall not, at preſent, ſay any Thing of its Characters.

This is preſerv'd in moſt curious Gardens, which have Collections of tender Plants. It is eaſily propagated by planting Cuttings during any of the Summer Months, in a Border of light Earth, which will take Root in ſix Weeks Time, provided they are water'd and ſhaded as the Seaſon may require; then they ſhould be taken up, with a Ball of Earth to their Roots, and planted into Pots fill'd with light, ſandy Earth, and may be expoſed to the open Air until *October*, at which Time they ſhould be remov'd into the Conſervatory, where they ſhould be plac'd as free as poſſible from being over-hung with other Plants: And, during the Winter-ſeaſon, they muſt be refreſh'd with Water, but ſhould not have too much given 'em each Time: You may let 'em have as much Air as the Weather would permit; for if they are kept too cloſe, they will be ſubject to grow mouldy, and generally decay ſoon after.

Theſe Shrubs may be train'd up either to form round Heads, or into Pyramids, it being a very manageable Plant; but ſhould not be often cut; for, by ſo doing, 'twill occaſion the Branches to grow very cloſe, whereby the Air will be excluded from the middle Part of the Plant, which will cauſe the Leaves to decay, and the Branches to appear very unſightly: But if you ſuffer it to grow as it is naturally diſpos'd, (only obſerving to tie up the Stem, to make it ſtrait) the Plant will thrive much better.

The Beauty of this Shrub is in its ſmall ever-green Leaves, which grow as cloſe as *Heath*; and being bruis'd between the Fingers, do emit a very fragrant Odour.

FRUTEX *Virginianus trifolius*, *Ulmi ſimilis. Baniſt. Pluk. Alm. American* Shrub Trefoil, with Fruit like the Elm.

The Seeds of this Shrub were ſent from *Carolina* by Mr. *Cateſby*, Anno 1724, from which ſeveral Plants have been rais'd in the Gardens near *London*, where it has flower'd for ſeveral Years paſt, and hath ſeveral Times form'd Seeds, which were very like thoſe of the *Elm-Tree*, but did not ripen.

This Shrub is hardy enough to reſiſt the ſevereſt Cold of our Climate in the open Air, provided it be planted on a dry Soil. It may be propagated by laying down the Side-branches into the Ground in the Spring, obſerving to ſlit them at a Joint, as it is practiſed in laying *Carnations.* When they are pegg'd down, the Earth ſhould be laid two or three Inches thick over the Part that is ſlit; and in dry Weather they ſhould be water'd, which, if duly attended to, will greatly facilitate their rooting; ſo that in one Year they will be rooted ſufficient to be tranſplanted out: But if they are not ſlit, nor the Ground about them watered in dry Weather, it will be two Years before they will be fit to tranſplant.

If the Plant likes the Soil into which it is planted, it will make conſiderable ſtrong Shoots, and the Leaves will be large and fair. There is one of theſe Shrubs in the *Phyſick-Garden* at *Chelſea*, which I rais'd from Seeds, *Anno* 1724, and has been tranſplanted ſeveral Years in the open Air, now upwards of ſix Feet high, and which hath flower'd five or ſix Years paſt; and, for its uncommon Appearance, is worthy a Place in every good Collection of Trees and Shrubs.

FRUTEX *ſcandens, petroſelini foliis, Virginianus, claviculis donatus, Pluk. Mant.* The Pepper-tree, *vulgo*.

This Plant was brought from *Virginia*, where it is found in great Plenty; as alſo in *South Carolina*, where it is one of the moſt common Plants, if we may judge by the Earth which hath been brought from thence; for theſe Plants do come up plentifully in that, as common Weeds. It was rais'd from Seeds in the Gardens of *Samuel Reynardſon*, at *Hillindon* near *Uxbridge*, many Years ſince, from whence it hath been diſtributed into many Gardens near *London*. There is no great Beauty in it; but for its Oddneſs it may have a Place in a Collection of Shrubs. It is extreme hardy, induring our ſevereſt Cold in the open Air, but ſhould be planted on a dry Soil, and will require a Stake to ſupport it; for its Branches are very flexible, and will trail upon the Ground, if they are not ſupported. The Flowers it produces are very ſmall, and of a greeniſh-yellow Colour, growing in Cluſters ſomewhat like thoſe of the Creeper; and the Branches do emit Claſpers, as that doth, to which it appears to me to be nearly related.

This Plant may be propagated by laying down the tender Branches, which in one Year will be rooted enough to tranſplant; or by Suckers from the Roots, which, when the Plants are arriv'd to a convenient Age, they will ſend forth in great Plenty.

FRUTEX PAVONIUS. *Vide* Poinciana.

FRUTICOSE, [*Fruticoſus*, Lat. *a Shrub*] are thoſe Plants which are of an hard, woody Subſtance, and do not riſe to the Height of Trees.

FUCHSIA. This Plant was ſo named by Father *Plumier*, who diſcovered it in *America*, in Honour to the Memory of *Leonard Fuchſius*, a learned Botaniſt.

The *Characters* are;

It hath a funnel-ſhaped Flower conſiſting of one Leaf, and divided into ſeveral Parts at the Brim; whoſe Cup afterward becomes a roundiſh ſoft fleſhy Fruit, which is divided into four Cells, which are full of roundiſh Seeds.

We have but one Sort of this Plant, *viz.*

FUCHSIA *triphylla, flore coccineo. Plum. Nov. Gen.* Three-leav'd Fuchſia, with a ſcarlet Flower.

This Plant is a Native in the warmeſt Parts of *America*; it was diſcovered by Father *Plumier*, in ſome of the *French* Iſlands in *America*, and was ſince found by the late Dr. *William Houſtoun*, at *Carthagena* in *New Spain*; from whence he ſent the Seeds into *England*.

This is propagated by Seeds, which muſt be ſown in Pots filled with rich light Earth, and plunged into a Hot-bed of Tanners-bark, obſerving to moiſten the Earth as often as it appears dry; and if the Nights ſhould prove cold, the Glaſſes of the Hot-bed ſhould be covered with Mats; but in the Day-Time, when the Sun is warm, the Glaſſes ſhould be raiſed with Stones, to let out the Steam which may ariſe in the Bed, and to admit freſh Air. In about a Month after the Seeds are ſown, the Plants will begin to appear, when they ſhould be carefully cleared from Weeds, and frequently refreſhed with Water to promote their Growth; and when they are about two Inches high, they ſhould be ſhaken out of the Pots, and ſeparated carefully; then plant each into a ſeparate ſmall Pot, filled with light rich Earth, and plunge them again into a Hot-bed of Tanners-bark, being careful to ſcreen them from the Sun, until they have taken new Root; after which Time they muſt have freſh Air admitted to them every Day in proportion to the Warmth of the Seaſon, and ſhould be frequently watered. When the Plants have grown ſo as to fill the Pots with their Roots, they muſt be tranſplanted into larger Pots, and plunged into the Hot-bed again, being careful to water them; and if they hang their Leaves on removing, they ſhould be ſcreened from the Sun until they have taken new Root: As the Seaſon advances, ſo the Glaſſes of the Hot-bed ſhould be raiſed higher, to admit a greater Share of Air to the Plants, to prevent their drawing up weak; and when the Plants are grown ſo tall as to reach the Glaſſes, they ſhould be removed into the Bark-ſtove, and plunged into the Tanners-bark. In Winter theſe Plants require to be kept very warm, and at that Seaſon they muſt not have ſo much Water as in Summer, but it muſt be often repeated.

Theſe Plants are too tender to thrive in the open Air in this Country, even in the hotteſt Part of the Year; therefore they ſhould conſtantly remain in the Stove, obſerving to let in a large Shair of freſh Air in Summer, but in Winter they muſt be kept warm: With this Management the Plants will produce their Flowers, and make a beautiful Appearance in the Stove, amongſt other tender exotic Plants.

FUMARIA, Fumatory.

The *Characters* are;

It hath divided Leaves reſembling thoſe of the umbelliferous Plants: The Flowers, which are collected into a Spike, are of an anomalous Figure, ſomewhat reſembling a papilionaceous Flower, conſiſting of two Petals or Leaves, which open like two Lips, the upper Lip ending in a Spur: The Foot-ſtalk is join'd to the Middle Part of the Flower: The Fruit is either of a long or a round Figure, which is like a Pod, in which are contain'd many roundiſh Seeds.

The *Species* are;

1. FUMARIA *Officinarum & Dioſcoridis, flore purpureo. C. B.* The common Fumatory, with a purple Flower.
2. FUMARIA *minor tenuifolia. C. B.* Leſſer narrow-leav'd Fumatory.
3. FUMARIA *ſemper-virens & florens, flore albo. Flor. Bat.* Ever-green Fumatory, with a white Flower.
4. FUMARIA *lutea. C. B.* Yellow Fumatory.
5. FUMARIA *bulboſa radice cava major. C. B.* Great bulbous-rooted Fumatory, or hollow Root.
6. FUMARIA *bulboſa radice cava major, flore albo. C. B.* Great bulbous-rooted Fumatory, with a white Flower.
7. FUMARIA *bulboſa, viridi flore. Tourn.* Bulbous-rooted Fumatory, with a green Flower.
8. FUMARIA *bulboſa, radice non cava, major. C. B.* Great bulbous-rooted Fumatory, with a Root not hollow.

The firſt of theſe Plants is ſometimes uſed in Medicine, but is ſeldom cultivated in Gardens, it being very common in arable Land in moſt Parts of *England*.

The ſecond Sort is not a Native of *England*, but is preſerv'd in ſome curious botanick Gardens for the ſake of Variety. Theſe are both annual Plants.

The third Sort is a perennial Plant, which, if planted in a dry Soil, and a warm Situation, will continue flowering almoſt the whole Year round, which renders it worthy of a Place in every good Garden.

The fourth Sort is alſo an abiding Plant, which requires the ſame Situation and Culture as the former. Theſe two Plants will grow in Joints or hollow Places in old Walls, which will render them leſs ſubject to decay than if they were planted in a rich Soil. They may be propagated by ſowing their Seeds ſoon after they are ripe; for if the Seeds are kept 'till the Spring, they very often miſcarry.

Theſe Plants may be ſuffered to grow on Walls, and in ſome abject Part of the Garden; for if they are admitted into the Borders of the Pleaſure-Garden, they will ſcatter their Seeds, and become troubleſome Weeds.

The fifth, ſixth, ſeventh, and eighth Sorts are propagated by Off-ſets, as other bulbous-rooted Flowers: Theſe produce their Flowers in the Beginning of *April*, and are very pretty Ornaments to Borders in a ſmall Flower-Garden. They are extreme hardy, but do not increaſe very faſt, ſeldom producing Seeds with us; and their Bulbs do not multiply very much, eſpecially if they are often tranſplanted. They love a light, ſandy Soil, and ſhould be ſuffer'd to remain three Years undiſturb'd, in which Time they will produce many Off-ſets. The beſt Seaſon for tranſplanting them is in *May*, when the Leaves begin to die off; for if they are taken up when their Leaves are freſh, it will greatly weaken their Roots.

FURZ. *Vide* Geniſta.

G A

GALE; The Sweet Willow, *or* Dutch Myrtle.

The *Characters* are;

The Leaves are placed alternately on the Branches: It hath Male Flowers, which are produced at the Wings of the Leaves, are naked, and grow in a longiſh Spike: The Fruit, which is produced in ſeparate Parts of the ſame Tree, is of a conical Figure, and ſquamoſe, containing one Seed in each Scale.

The *Species* are;

1. GALE *frutex odoratus, ſeptentrionalium Eleagnus, cordi,*

Chamæleagnus Dodonæi. J. B. Sweet Gale, Sweet Willow, or Dutch Myrtle.

2. Gale *quæ Myrto Brabanticæ ſimilis, Carolinienſis baccata, fructu racemoſo ſeſſeli monopyreno. Pluk. Phyt.* Candle-berry-tree, *vulgo*.

3. Gale *quæ Myrto Brabanticæ ſimilis, Carolinienſis humilior, foliis latioribus, & magis ſerratis. Cateſb. Hiſt. Nat. Carol.* The Dwarf broad-leav'd Candle-berry-tree, with deeply-ſerrated Leaves.

The firſt of theſe Plants is very common in ſeveral Parts of *England*, growing upon Bogs which have an open Situation: This is with Difficulty preſerv'd in Gardens: It muſt have a very moiſt Soil, and ſhould have an open Situation. The beſt Seaſon for tranſplanting theſe Shrubs is in the Beginning of *March*, juſt before their green Leaves appear: In removing them, you ſhould be careful to preſerve as much Earth about their Roots as poſſible; as alſo to water them plentifully, if the Seaſon ſhould prove dry. They are propagated by Suckers, which are produced in great Plenty from their Roots, when they are planted on a proper Soil, but ſeldom do make any conſiderable Increaſe in Gardens: However, any one that has a mind to plant theſe Shrubs in a Garden, or other Plantation, may be ſufficiently ſupply'd from the Bogs, where they grow ſpontaneouſly.

The ſecond and third Sorts are both Natives of *America*, and have been rais'd from Seeds which came from thence, but are both hardy enough to reſiſt the Cold of our Climate in the open Air. Theſe are alſo propagated by Suckers, as the former; which, if they are planted in a moiſt Soil, and ſuffer'd to remain undiſturb'd, they will produce in great Plenty: They may alſo be increas'd by laying down their tender Branches, which ſhould be ſlit, as is practis'd in laying of *Carnations*; and will take Root in one Year, and then may be tranſplanted where they are to remain. The Seeds of theſe Plants, when brought from Abroad, ſhould be ſown in Pots fill'd with freſh loamy Earth, and then plung'd into a moderate Hot-bed, which will greatly forward their coming up: And as the Seaſon advances, the Pots ſhould, by Degrees, be removed out of the Hot-bed into the open Air, that they may be harden'd before Winter; and in *October* you ſhould place the Pots into a common Hot-bed Frame, that may be cover'd in hard froſty Weather, which often injures them while they are young, but afterwards they are not liable to any Misfortune from the Seaſons: The beſt Time to remove theſe is in the Spring, juſt before they begin to ſhoot; but you ſhould cover the Surface of the Ground round their Roots after they are planted, to prevent the Sun and Wind from entering the Ground to dry their Fibres.

Theſe Shrubs are all of a low Stature with us, ſeldom riſing above five Feet high, and ſhould therefore be planted amongſt Shrubs of the ſame Growth; for they will by no means grow under the Shade of other Trees: They are very proper Plants for ſmall Wilderneſs-quarters in a ſwampy Piece of Ground, where few other Plants will thrive well.

The firſt Sort caſts its Leaves in Winter, but the two other Sorts are ever-green: The Leaves of all theſe Plants, when bruis'd, do emit a very pleaſant Odour, not much unlike that of the *Myrtle*; from whence the People have been induc'd to give them that Epithet. The Inhabitants of *America* do prepare a Wax from the Fruit of thoſe two Plants, with which they make very good *Candles*, which burn very well, and have a very agreeable Scent.

The two laſt mentioned Sorts do produce Flowers in ſeveral Gardens near *London*; and the firſt of them did produce Fruit, in the Year 1729, in the curious Garden of Mr. *Peter Collinſon* at *Peckham*; but the laſt Sort hath not, as yet, produced Fruit in *England*, that I have heard.

GALEGA; Goat's Rue.

The *Characters* are;

It hath a perennial Root: The Leaves grow by Pairs, faſten'd to a Mid-rib, terminating in an odd Lobe: The Flower is of the papilionaceous Kind, conſiſting of a Standard, the Wings, and the Keel: The Pointal becomes a long taper Pod, which is fill'd with oblong Kidney-ſhap'd Seeds.

The *Species* are;

1. Galega *vulgaris, floribus cæruleis. C. B.* Common Goat's Rue, with blue Flowers.

2. Galega *vulgaris, floribus penitus candicantibus. C. B.* Common Goat's Rue, with white Flowers.

3. Galega *vulgaris, floribus ex cæruleo purpureis. C. B.* Common Goat's Rue, with bluiſh purple Flowers.

4. Galega *Africana, floribus majoribus, & ſiliquis craſſioribus. Tourn. African* Goat's Rue, with large Flowers, and thick Pods.

5. Galega *Americana, foliis ſubrotundis, floribus coccineis. Houſt. American* Goat's Rue, with roundiſh Leaves, and ſcarlet Flowers.

6. Galega *Americana fruteſcens, flore purpureo, foliis ſericeis. Plum.* Shrubby *American* Goat's Rue, with ſilken Leaves.

The firſt of theſe Plants is propagated in Gardens for medicinal Uſe; and the ſecond and third Sorts are only Varieties of the firſt, from which they only differ in the Colour of their Flowers, and are for Variety preſerv'd in ſome curious Gardens; but the fourth Sort is a diſtinct Species, having much larger Leaves, Flowers, and Pods.

Theſe Plants may be propagated either from Seeds, or by parting of their Roots. The beſt Seaſon for ſowing the Seeds is in the Beginning of *March*, in a light Soil, and an open Situation; and when the Plants are come up, you ſhould either hough between them to deſtroy the Weeds, (as is practis'd for *Onions*, *Carrots*, &c.) or elſe pull out the Weeds with your Hands, cutting down, or pulling up the Plants where they are too cloſe to each other, that thoſe left may have Room to get Strength; and ſo from time to time, as the Weeds come up, you muſt be very careful to deſtroy them, as alſo to cut up, or draw out the Plants, where they are too thick; for they ſhould not be left cloſer than eight or nine Inches Diſtance from each other. The ſecond Year theſe Plants will flower, and produce ripe Seeds: But if you intend to continue your Plants for Uſe, you ſhould cut off the Herb when it is in flower, and not permit it to ſtand until it ſeeds, which very often cauſes the Plants to decay. Theſe Roots may alſo be parted into ſmall Heads in Autumn for Increaſe: But the ſeedling Plants are much preferable to theſe Off-ſets; ſo that the beſt way is to propagate this Plant by ſeeds.

The fifth Sort was diſcovered by the late curious Botaniſt Dr. *William Houſtoun*, at *Campechy*, from whence he ſent the Seeds into *Europe*. Theſe Plants are Annuals, and muſt be raiſed on a Hot-bed early in the Spring; and when they are fit to tranſplant, ſhould be each put into a ſeparate Half-penny Pot, filled with freſh light Earth, and plunged into a moderate Hot-bed of Tanners-bark, obſerving to ſcreen them from the violent Heat of the Sun, until they have taken Root; after which time they ſhould have a large Share of freſh Air admitted to them in warm Weather, and muſt be frequently watered. When theſe Plants have filled the Pots with their Roots, they ſhould be gently ſhaken out, being careful to preſerve as much of the Earth to their Roots as poſſible, and put into Pots a Size larger, filling them up with the like freſh Earth, and plunged into the Hot-bed again, obſerving to water and give Air to them as before: with this Management they will flower in *July*, and in *September* they will perfect their Seeds, and the Plants will ſoon after decay.

The ſixth Sort is alſo a Native of *America*, and was diſcovered by Father *Plumier*; this is alſo propagated by Seeds, which ſhould be ſown on a Hot-bed in the Spring; and when the Plants are come up, they muſt be tranſplanted, and treated in the ſame Manner as hath been directed for the former Sort; but this being a ſhrubby Plant of a longer Continuance, muſt be placed in the Bark-ſtove in the Winter, and ſhould be treated after the Manner of other tender exotic Plants; for it ſeldom flowers until the third Year, and if the Plants are removed abroad in Summer, will ſcarcely ever flower in this Country.

GALEOPSIS; Stinking Dead Nettle.

The *Characters* are;

It hath a labiated Flower of one ſingle Leaf, whoſe upper Lip is hollow like a Spoon, but the under one is divided into three Segments, the middle Part being large: The Cup of the Flower is Funnel-ſhap'd, and divided into five Parts, and each Flower is ſucceeded by four naked Seeds.

The *Species* are;

1. Galeopsis *Hiſpanica fruteſcens, teucrii folio. Tourn. Spaniſh*, ſhrubby, ſtinking Dead Nettle, with a Tree-Germander-leaf.

2. Galeopsis *quod lamium, fruticans, teucrii folio lucido, calyce & flore magno candido, tantilla purpura varie notato. H. C.* Shrubby ſtinking Dead Nettle, with a ſhining Tree-Germander-leaf, and a large white Flower variegated with ſmall purple Spots.

3. Galeopsis *anguſtifolia Cretica viſcoſa. Boerh. Ind. alt.* Narrow-leav'd viſcous ſtinking Dead-nettle of *Candy*.

4. Galeopsis *procerior fœtida ſpicata. Tourn.* Common Hedge-nettle.

5. Galeopsis *ſive urtica iners, flore luteo. J. B.* Yellow Archangel, or Dead-nettle.

6. Galeopsis *procerior fœtidiſſima, ſpicâ longiſſimâ albâ. Michel.* The moſt ſtinking taller Hedge-nettle, with a long white Spike.

The two firſt Plants ariſe to the Height of three Feet, or more, do grow ſhrubby, and may be train'd to regular Heads, whereby they will appear very agreeable, being always green, and continue flowering moſt Part of the Summer; and altho' the Flowers are not very beautiful, yet for their long Continuance in Flower, together with the Variety of their Leaves, they deſerve a Place in every good Garden.

Theſe Plants may be propagated by Seeds or Cuttings, as alſo from Suckers, which ariſe about their Stems: If you would propagate them by Seeds, you muſt prepare a Spot of good freſh light Earth, which ſhould be well digg'd and looſen'd, and made very fine and level; into which in *March* you ſhould ſow the Seeds, covering them with the ſame light Earth about half an Inch thick: When the Plants are come up, which will be towards the Middle or latter End of *April*, you ſhould carefully weed them, and in very dry Weather you ſhould give them a little Water: In *Auguſt* you ſhould take up ſome of the Plants carefully, and plant them into Pots fill'd with freſh light Earth, that they may be ſhelter'd, during the Winter Seaſon, under a common Hot-bed Frame; for theſe Plants are ſomewhat tender while young, but when they are grown woody, will reſiſt the ſevereſt Cold in the open Air, provided they are planted in a dry Soil: In the Spring, after the cold Weather is paſt, you may ſhake the Plants out of the Pots, preſerving the Earth to their Roots, and plant them in the Places where they are to remain, and in the ſucceeding Summer they will produce Flowers and Seeds.

If you would propagate them by Cuttings, you ſhould cut off ſuch only as are young and thriving in *May*, and plant them in a ſhady Border, watering them as the Seaſon requires; and in *Auguſt* you ſhould take up ſuch of them as have taken Root, planting them into Pots, and managing them as was directed for the Seedling Plants.

The third Sort is a Plant of humbler Growth than either of the two Sorts above mentioned; this ſeldom riſes above a Foot high, nor doth it ever become ſo woody; it is very clammy, and has a very ſtrong bituminous Scent. This may be propagated by ſowing of the Seeds in *March*, on an open Bed of light Earth; and when the Plants begin to appear, they ſhould be carefully cleared from Weeds, and in dry Weather muſt be often refreſhed with Water. When the Plants have obtained Strength enough to be tranſplanted, they ſhould be carefully taken up; and ſome of them muſt be put into Half-penny Pots, filled with freſh light Earth; and the others may be planted in warm Borders, obſerving to water and ſhade them until they have taken Root; after which time, thoſe which were planted into the Borders, will require no farther Care but to keep them clear from Weeds, and other Plants; and if the Winter proves favourable, they will ſucceed very well; but for fear theſe ſhould be deſtroyed, you ſhould place thoſe which were planted into Pots, under a common Hot-bed Frame in Winter, where they ſhould be expoſed to the open Air in mild Weather; but in froſty Weather they ſhould be covered to preſerve them. The following Summer, theſe Plants will produce Flowers and Seeds, but the Plants may be preſerved three or four Years, provided they are ſheltered in Winter.

The fourth and fifth Sorts grow wild in moſt Parts of *England*, ſo are ſeldom preſerved, except in botanic Gardens, for the ſake of Variety; theſe grow under Hedges, and in ſhady Woods, where they ſpread and increaſe by their creeping Roots. The fourth Sort is ſometimes uſed in Medicine.

Theſe Plants being eſteemed as Weeds, they are neglected by moſt Perſons; tho', if they are planted under Trees in large Wilderneſs Quarters, they will thrive and make a pretty Appearance when they are in Flower. The Roots of theſe Plants may be taken up at *Michaelmas*, from the Woods and Places of their Growth, and tranſplanted into the Wilderneſs, allowing them a large Share of Room, becauſe they ſpread very far by their creeping Roots; ſo that they ſhould be planted in large Tufts at a great Diſtance from each other; and in the Spring they will riſe about two Feet high, and produce their Flowers in great Plenty, when they will afford an agreeable Variety, in ſuch Places where few other Plants will thrive: ſo that by introducing ſome of theſe common Plants into Gardens, there may be a great Variety produced in Wilderneſſes, where the Ground is often bare, and doth not produce any kind of Plants, which afford no pleaſing Proſpect to Perſons who walk thro' the ſhady Paths of theſe Quarters; for it is much better to ſee any of the moſt common Weeds covering the Surface of the Ground amongſt the Trees, than to have it quite bare. But theſe Plants afford an agreeable Proſpect when they are in Flower, and require very little Culture.

The ſixth Sort was diſcovered in *Italy*, by Seignior *Micheli*, Profeſſor of Botany to the late Duke of *Tuſcany*, who ſent the Seeds into *England*; this is full as hardy as either of the former Sorts, and may be propagated in the ſame Manner.

GALLERIES. In order to make a *Gallery* in a Garden, with Portico's and Arches, a Line muſt firſt be drawn of the Length you deſign the *Gallery* to be; which being done, is to be planted with *Horn-beam*, as directed under the Article *Horn-beam*; which *Horn-beams* thus planted, are to be the Foundation of the *Gallery*.

The Management of them is not very difficult, they require only to be digg'd about and ſhear'd a little when there is Occaſion.

The chief Curioſity requir'd is in the ordering the Forepart of the *Gallery*, and in forming the Arches.

Each Pillar of the Portico's or Arches ought to be four Feet diſtant one from the other; the *Gallery* twelve Feet high, and ten Feet wide, that there may be Room for two or three Perſons to walk a-breaſt.

When the *Horn-beams* are grown to the Height of three Feet, the Diſtance of the Pillars well regulated, and the Ground-work of the *Gallery* finiſh'd, the next thing to be done is to form the Frontiſpiece: To perform which, you muſt ſtop the *Horn-beam* between two Pillars at the Height, and run up a Trellis made for that Purpoſe, which forms the Arch.

As it grows up, you muſt with your Shears even thoſe Boughs that out-ſhoot the others: In time they will grow ſtrong, and may be kept in Form by the Shears.

Portico Galleries may be cover'd with *Lime-trees*.

Theſe *Galleries* were formerly much eſteem'd in *France*, *Italy*, and other hot Countries, but in *England* they are ſeldom made.

GALLIUM; Ladies Bed-ſtraw, *or* Cheeſe-Runnet.

The *Characters* are;

It is a Plant of the ſtellate Kind; the Leaves, which are neither rough nor knappy, are produc'd at the Joints of the Stalks, five or ſix in Number, in a radiant Form: The Flower conſiſts of one Leaf, which is expanded toward the upward Part, and divided into ſeveral Segments; each of theſe Flowers are ſucceeded by two naked Seeds.

The *Species* are;

1. Gallium *luteum. C. B.* Yellow Ladies Bed-ſtraw.
2. Gallium *rubrum. C. B.* Red Ladies Bed-ſtraw.
3. Gallium *nigro-purpureum tenuifolium. Col.* Narrow-leav'd Mountain Ladies Bed-ſtraw, with dark purple Flowers.
4. Gallium *ſaxatile, glauco folio. Bocc. Rar.* Ladies Bed-ſtraw of the Rocks, with a glaucous Leaf.
5. Gallium *ſaxatile, glabro folio. Bocc. Rar.* Ladies Bed-ſtraw of the Rocks, with a ſmooth Leaf.

The firſt of theſe Plants (which is the Sort commonly us'd in Medicine) is very common in moiſt Meadows, and in Paſture-grounds in ſeveral Parts of *England*: The other Varieties are preſerv'd in curious Botanick Gardens; but as they are Plants of very little Beauty, and are ſubject to ſpread very very far, and over-run whatever Plants grow near them, ſo they are ſeldom cultivated in other Gardens.

Theſe Sorts may, any of them, be propagated by parting their Roots, which ſpread and increaſe very faſt, either in the Spring, or Autumn, and will grow almoſt in any Soil or Situation, eſpecially the firſt Sort: The other Sorts do require a drier Soil, but will all grow in any Situation.

GARDENS are diſtinguiſh'd into *Flower-gardens*, *Fruit-gardens*, and *Kitchen-gardens*: The firſt for Pleaſure and Ornament, and therefore to be plac'd in the moſt conſpicuous Parts, *i. e.* next to, or juſt againſt the back Front of the Houſe; the two latter for Service, and therefore made in bye Places.

In the Choice of a Place to plant a *Garden* in, the Situation and Expoſure of the Ground are the moſt eſſential Points to be regarded; becauſe the Succeſs of all depends upon a good Choice: for if a Failure be made in that Point, all the Care and Expence will in a manner be loſt; but if a good Choice be made, the Trees, *&c.* that ſhall be planted on it will in a ſhort Time thrive, and become both tall and beautiful.

In a *Garden*, the principal Things to be conſider'd, are the *Situation*, *Form*, *Soil*, and *Aſpect* or *Expoſure*.

As for the *Form*, a Square, or rather an Oblong, is moſt eligible, when leading from the Middle of the Houſe, with a Gravel Walk in the Midſt, having narrow Verges of Graſs on each Side, and Rows of Variety of Winter-greens on either Side of the Graſs Verges. But if the Ground be irregular, it may be made uniform ſo as to afford a Proſpect no ways inferior to the moſt regular. The moſt irregular Figure may be reduc'd into Order by ſtrait Lines. There is Beauty in a Triangle, as well as a Square; and the moſt irregular Spots of Ground may be brought to thoſe two Figures by Borders and Walks.

An Irregularity is eaſily hid in a large *Garden*, by long Walks and tall Hedges interrupting a diſtant View: And the little Corners and triangular Spaces may be agreeably fill'd up with Borders of Flowers, Dwarf-trees, flowering Shrubs, or Ever-greens. Nor ſhould we be ſolicitous to throw the whole *Garden* into one ſingle View; ſince Irregularities and Unevenneſſes oftentimes afford many uncommon pretty Devices, *&c.*

1ſt. *Situation*: This ought to be ſuch a one as is wholeſome, in a Place that is neither too high nor too low; for if a *Garden* be too high, it will be expos'd to the Winds, which are very prejudicial to Trees: if it be too low, the Dampneſs of low and marſhy Places will be very injurious to Health; beſides, the Vermin and venomous Creatures, that breed in Ponds and marſhy Places, add much to the Inſalubrity of them: Therefore, Situations in mountainous Places, or in the Bottoms of Vallies, ſhould not be choſen; but thoſe which are on the Side of an Hill are the more happy.

A Situation on a riſing Ground is moſt eſteem'd; and indeed, if it be not too ſteep, has the moſt Advantages, if the Slope be eaſy and imperceptible, and a good deal of Level may be had.

If the Declivity be eaſy and inſenſible, and abounds in Springs of Water, the Situation is very happy, and the moſt agreeable that can be; for being ſhelter'd from the Fury of the Winds, and the violent Heat of the Sun, there a temperate Air will be enjoy'd; and the Water that deſcends from the Top of the Hills, either from Springs or Rain, will ſupply Fountains, Canals, and Caſcades, for Ornaments of Gardens; and beſides this, when it has perform'd its Office, will water the adjacent Vallies, and render 'em fertile and wholeſome, if it be not ſuffer'd to ſtagnate there.

Indeed, if the Declivity of the Hill be too ſteep, and the Water in too great a Quantity, then a *Garden* on the Side of it may often ſuffer, by having the Trees torn up by the Torrents and Floods, and the Earth above tumbled down on that below, the Walls thrown down, and the Walks ſpoil'd.

If the Situation be on a Plain or Flat, it has ſeveral Advantages; Floods and Rains make no Spoil: The Air is even more pure than upon the Side of an Hill: There is a continu'd Proſpect of Champains, interſected by Rivers, Ponds, and Brooks, fine Meadows, and Hills cover'd with Buildings or Woods. The level Surface is leſs tireſome to walk on, and leſs chargeable than that on the Side of an Hill, Terrace-walks and Steps not being neceſſary; but the greateſt Diſadvantage of flat Gardens, is the Want of an extenſive Proſpect, which riſing Grounds afford.

2dly, The ſecond thing to be conſider'd in chuſing a Plat for a *Garden*, is a good Earth or Soil.

It is ſcarce poſſible to make a fine *Garden* in a bad Soil: And tho' there are Ways to meliorate Ground, they are very expenſive; and ſometimes, when the Expence has been beſtow'd, of laying good Earth three Feet deep over the whole Surface, when the Roots of the Tree have reach'd the natural Bottom, a whole *Garden* has been ruin'd.

A good Soil is that which of its own Nature is rich and fruitful: And if the Expoſure be Southerly and healthful, and poſſeſs'd of all the Advantages before-mention'd, yet ſtill, if it has not a good Body of Earth, and that which is fertile in it ſelf, it is to be fear'd, that whatever is planted in it, will, in a while, droop and die away.

To judge of the Quality of the Soil, obſerve whether there be any Heath, Thiſtles, or ſuch like Weeds growing ſpontaneouſly therein, which are certain Signs that the Ground is poor. Likewiſe, if there be large Trees growing thereabouts, obſerve whether they grow crooked, ill-ſhap'd and grubby, of a faded Green, and full of Moſs, or infeſted with Vermin; if ſo, the Place is to be rejected; but, on the contrary, if it be cover'd with good Graſs fit for Paſture, then you may be encourag'd to try the Depth of the Soil.

To know this, dig Holes in ſeveral Places ſix Feet wide, and four Feet deep: If you find three Feet of good Earth, it will do well, but leſs than two will not be ſufficient.

The Quality of good Ground, is neither to be ſtony, nor too hard to work; neither too dry, nor too moiſt; nor too ſandy and light; nor too ſtrong, as rank and clayey, which is the worſt of all for *Gardens*.

3dly, The third Requiſite is Water. If this be wanting to a *Garden*, it is one of the greateſt Inconveniencies that can attend it, and will bring a certain Mortality upon whatever is planted. By watering, the great Droughts in Summer are allay'd, which would otherwiſe burn up all the Plants; beſides the Uſefulneſs of it in fine *Gardens*, for making *Jets d'Eau*, *Canals*, *Caſcades*, &c. which are the greateſt Ornaments of a *Garden*.

4thly, The fourth Thing requir'd in a good Situation, is the View and Proſpect of a fine Country; and tho' this is not ſo abſolutely neceſſary as the preceding, yet it is one of the moſt agreeable.

If a *Garden* was planted in a low Place that was bury'd, and that had no kind of Proſpect, it would be both diſagreeable and unwholſome; the Trees themſelves being too much ſhaded and obſcur'd, would not look near ſo beautiful: whereas a fine View, and the Proſpect of a noble Country, are as agreeable Entertainments as a *Garden* can afford.

In ſhort, a *Garden* neceſſarily requires the Sun, a good Soil, the Care of the Gardener, and Water; and the laſt, above all, is indiſpenſably neceſſary: 'Without any of theſe, there's no Good to be expected; and it would be egregious Folly to plant a *Garden* where any of theſe are wanting.'

Of the Deſigning or Manner of Laying out a Fine or Pleaſure-Garden.

The Area of a handſome *Garden* may take up thirty or forty Acres, not more.

And as for the Diſpoſition and Diſtribution of this *Garden*, the following Directions may be obſerved.

1ſt, There ought always to be a Deſcent from the Houſe to the *Garden* not fewer than three Steps. This Elevation of the Building will make it more dry and wholſome: Alſo, from the Head of theſe Steps there will be a farther Proſpect or View of the *Garden*.

In a fine *Garden*, the firſt Thing that ſhould preſent itſelf to the Sight, ſhould be an open level Piece of Graſs, full as broad as the Length of the Front of the Building, which may be ſurrounded by a Gravel Walk, for the Conveniency of walking in wet Weather.

Theſe Pieces of Graſs ſhould not be divided in the Middle with a Gravel Walk, (as is too frequently ſeen;) for it is much more agreeable to view an intire Carpet of Graſs from the Houſe, than to have it interſected by Walks. On the oppoſite Side of the Gravel Walks may be Borders four Feet wide for Flowers, which will ſufficiently anſwer the Purpoſe of *Parterres*; and if from the Back of theſe Borders there are Ever-greens planted in ſuch a manner, as to riſe from the Borders gradually, ſo as to form an Ever-green Slope, it will bound the Proſpect very agreeably; and where there are any Objects worthy the Sight, or diſtant Proſpects to be obtain'd, there ſhould be the Viſta's left.

Groves make the Chief of a *Garden*, being great Ornaments to all the reſt of its Parts; ſo that there cannot be too many of them planted, provided they are not too cloſe to the Building, ſo as to render it damp and unwholſome; nor ſhould they be placed ſo as to obſtruct the Proſpect of agreeable Objects.

To accompany *Parterres*, it is uſual to make Choice of thoſe Deſigns of Wood-work that are the fineſt: as *Groves* open'd in Compartiments, *Quincunces*, *Verdant Halls*, with *Bowling-greens*, *Arbour-work*, and *Fountains* in the Middle.

Theſe ſmall Groves being placed near the Houſe, are ſo much the more agreeable, in that you have no need to go far to find Shades; and beſides this, they communicate a Coolneſs to the Apartments, which is very agreeable in hot Weather.

It would alſo be very proper to plant ſome Groves of Evergreens, that may afford the Pleaſure of ſeeing a Wood always verdant in Winter, when the other Trees and Plants are deprived of their Ornaments; and alſo to plant ſome Squares of them to be a Diverſity from the other Woods.

It is alſo uſual to adorn the Head of a *Parterre* with Baſons, Water-works; and beyond it, with a circular Line of Paliſades or Wood-work cut into a Gooſe-foot, leading into the great Walks, and to fill the Space between the Baſon and the Paliſade with ſmall Pieces of Embroidery or Graſs-work, ſet off with Yews, Vaſes, and Flower-pots.

In *Gardens* which have Terraces either in the Side or Front of the Houſe, where there is a delightful Proſpect, ſo that you cannot ſhut up the *Parterre* by a circular Paliſade; in order to continue the new View, you ſhould lay ſeveral Compartiments of a *Parterre* together, ſuch as *plain Green-plots*, after the modern Faſhion, or *Cut-work*: which ought to be divided at convenient Diſtances by Croſs-walks: But the *Parterre*, or *plain Green-plot*, muſt always be next to the Houſe, becauſe it is very agreeable to the Eye.

The principal Walk muſt be in the Front of the Houſe, and ſhould extend from the *Graſs-plot* next the Houſe, to the End of the *Garden*: If they be very wide, the Side ſhould be turfed next the Borders, and at the Ends they may be terminated by a Foſſe, to continue the View.

If any Part of the Ground be naturally low and marſhy, and you would not be at the Expence of filling it, you may in ſuch Places make *Bowling-greens*, *Water-works*, and *Groves*, raiſing the Allies only to the Levels of thoſe that are near them, and that lead thither.

When the great Lines and chief Walks are laid out, and the Parterres and Works about the Sides and Head of them are diſpoſed ſo as is moſt ſuitable to the Ground, then the reſt of the *Garden* is to be furniſh'd with many different Deſigns; as *Tall Groves*, *Cloſe Walks*, *Quincunces*, *Galleries*, and *Halls of Verdure*, *Green Arbours*, *Labyrinths*, *Bowling-greens*, and *Amphitheatres*, adorn'd with *Fountains*, *Canals*, *Figures*, &c. which Sort of Works diſtinguiſh a Garden well, and do alſo greatly contribute to the rendering of it magnificent.

Alſo the ſeveral Parts of each Piece ought to be diverſify'd: If a Baſon be round, the Walk ought to be octangular: And the like is to be obſerv'd as to *Graſs-plots* and *Bowling-greens* which are the Midſt of *Groves*.

The ſame Works ought never to be repeated on both Sides, except in open Places, where the Eye, by comparing them together, may judge of their Conformity, as in Parterres, Bowling-greens, Groves, open'd in Compartiments and Quincunces: But in ſuch Groves as are form'd of Paliſades and tall Trees, the Deſigns and Out-parts ought always to be varied: But tho' they are to be different, yet however they ought always to have ſuch Relation and Agreement one to the other in their Lines and Ranges, as to make the Openings, Glades, and Viſta's regular and agreeable.

In the Buſineſs of Deſigns, a mean and pitiful Manner ought to be ſtudiouſly avoided, and the Aim ſhould always be at that which is great and noble; not to make *Cabinets* and *Mazes* ſmall, and *Baſons* like Bowl-diſhes, and *Allies* ſo narrow that two Perſons can ſcarce walk in them. It is much better to have but two or three Things pretty large, than four times the Number of ſmall ones, which are but Trifles.

Before the Deſign of a *Garden* be put in Execution, it ought to be conſider'd what it will be in twenty or thirty Years time, when the Paliſades are grown up, and the Trees are ſpread: For it often happens, that a Deſign, which looks handſome when it is firſt planted, and in good Proportion, becomes ſo ſmall and ridiculous in Proceſs of Time, that there is a Neceſſity either to alter it, or deſtroy it intirely, and ſo plant it anew.

The Corners and Angles of every Part of a *Garden* ought to be ſlop'd, or cut hollow: This will make the Croſs-paths more agreeable to the Eye, and more convenient for walking, than to find Points and Corners advancing, which look very ill upon the Ground, and are very inconvenient.

The ſeveral Sorts of *Gardens* may be diſtinguiſh'd under three Heads: 1. *Gardens* on a perfect Level. 2. *Gardens* on an eaſy Aſcent. And, 3. *Gardens* whoſe Ground and Level are ſeparated and interrupted by Falls and Terraces, Banks, Slopes, Flights of Steps, *&c.*

Gardens on a perfect Level are the beſt, as well for the Conveniency of Walking, as that their long Allies and Glades have no Riſings nor Fallings, and are not ſo chargeable to maintain as the other.

Gardens on a gentle Aſcent are not quite ſo agreeable and convenient, altho' the Shelving be ſo little as not to be perceiv'd; for it fatigues and tires a Perſon to walk either up Hill or down Hill, without finding ſcarcely a reſting Place: Theſe ſloping Grounds are alſo liable to be ſpoil'd by Torrents.

There is a peculiar Excellency in *Gardens* that have Terraces; becauſe from the Height of one Terrace, all the lower Parts of the *Garden* may be diſcovered; and from others, the Compartiments are ſeen, which form ſo many ſeveral *Gardens* one under another, and preſent us with very agreeable Views, and different Scenes of Things, if the Terraces are not too frequent, and there be good Lengths of Level between them.

Theſe *Gardens* alſo lie advantageouſly for Water, which may be repeated from one another; but they are a great Charge to keep them up, as well as that they coſt a great deal the making.

The general Diſtribution of a *Garden*, and of its Parts, ought to be accommodated to theſe different Situations: For an excellent Deſign which would be proper for a *Garden* that is flat and upon a Level, would not ſerve for a Ground cut aſunder by divers Terraces, which break off both the Level and the Continuity.

There are, beſides theſe, many other Rules relating to the Proportions, Conformity, and Place of the different Parts and Ornaments of *Gardens*; of which more may be ſeen under other Articles.

GARIDELLA. *This Plant was ſo named by Dr.* Tournefort, *in Honour to Dr.* Garidel, *who was Profeſſor of Phyſick at* Aix *in* Provence.

The *Characters* are;

It hath a Roſe-ſhaped Flower, conſiſting of ſeveral horned Petals, which are bifid, and ranged in a circular Order; from whoſe many-leav'd Cup riſes the Pointal, which afterward becomes a Head compoſed of many oblong Pods, which open lengthways, and are full of roundiſh Seeds.

We know but one *Sort* of this Plant, *viz.*

GARIDELLA *foliis tenuiſſime diviſis. Tourn.* Garidella with very narrow-divided Leaves.

This Plant is very near a-kin to the *Nigella*, or *Fennel-Flower*; to which *Genus* it was plac'd by the Writers of Botany before Dr. *Tournefort*, and was by him ſeparated from it, as differing in the Form of the Flower.

It grows wild in *Candy*, and on *Mount Baldus* in *Italy*, as alſo in *Provence*, where it was diſcovered by Dr. *Garidel*, who ſent the Seeds to Dr. *Tournefort*, for the *Royal Garden* at *Paris*.

This is an annual Plant, whoſe Seeds ſhould be ſown in the Spring, on a Bed or Border of light freſh Earth, where the Plants are deſigned to remain (for they ſeldom thrive, if they are tranſplanted): when the Plants are come up, they muſt be carefully cleared from Weeds; and where they are too cloſe, they muſt be thinned, leaving them about four or five Inches apart; and as they grow up, ſo they muſt conſtantly be kept clear from Weeds, which, if ſuffer'd to grow amongſt the Plants, will ſoon over-bear and deſtroy them. In *June* theſe Plants will produce their Flowers, and in *Auguſt* the Seeds will ripen; which if permitted to fall, will come up in Autumn, and require no other Culture, but to keep them clear from Weeds.

GENERATION, is by Naturaliſts defin'd to be the Act of procreating and producing a Thing which before was not; or, according to the School-men, it is the total Change or Converſion of a Body into a new one, which retains no ſenſible Part or Mark of its former State.

Thus we ſay, Fire is *generated*, where we perceive it to be where before there was only Wood, and other Fuel; or when the Wood is ſo chang'd as to retain no ſenſible Character of Wood: In the like Manner a Chick is ſaid to be *generated*, when we perceive a Chick, where before was only an Egg, or the Egg is changed into the Form of a Chick.

In *Generation* there is not properly any Production of new Parts, but only a new Modification or Manner of Exiſtence of the old ones; and thus *Generation* is diſtinguiſh'd from *Creation*.

Generation alſo differs from *Alteration*, in that in *Alteration* the Subject remains apparently the ſame, and is only chang'd in its Accidents or Affections; as Iron, which before was ſquare, is now made round; or when the ſame Body which is well To-day, is ſick To-morrow.

Again: *Generation* is the Oppoſite to *Corruption*, which is the utter Extinction of a former Thing; as, when that which before was an Egg, or Wood, is no longer either the one, or the other. Whence it appears, that the *Generation* of one Thing is the *Corruption* of another.

The *Peripateticks* explain *Generation* by a Change or Paſſage from a Privation or Want of a ſubſtantial Form, to the having ſuch a Form.

The *Moderns* allow of no other Change in *Generation* than what is *local*; and according to their Notion, it is only a Tranſpoſition, or new Arrangement of Parts; and, in this Senſe, the ſame Matter is capable of undergoing an infinite Number of *Generations*.

As for Example: A Grain of Wheat being committed to the Ground, imbibes the Humidity of the Soil, becomes turgid, and dilates to ſuch a Degree, that it becomes a *Plant*, and, by a continual Acceſſion of Matter, by Degrees, ripens into an Ear, and at length into a Seed: This Seed, when ground in a Mill, appears in the Form of a Flower, which being mix'd up with Water, makes a Paſte, of which *Bread* is *generated* by the Addition of Yeſt, and undergoing the Operation of Fire, *i. e.* by baking; and this Bread being communicated by the Teeth, digeſted in the Stomach, and convey'd thro' the Canals of the Body, becomes *Fleſh*, or, in other Words, *Fleſh is generated.*

Now the only Thing effected in all this Series of *Generation*, is a local Motion of the Parts of the Matter, and their ſettling again in a different Order: So that where-ever there is a new Arrangement or Compoſition of the Elements, there is, in Reality, a new *Generation*; and thus *Generation* is reduced to *Motion*.

Generation is more immediately underſtood of Animal and Vegetable Bodies from Seed, or the Coition of others of different *Sexes*, but of the ſame *Genus* or *Kind*.

Monſ. *Perrault*, and ſome of the modern Naturaliſts after him, maintain'd, That there is not properly any new *Generation*; That God created all Things at firſt; and, That what is by us call'd *Generation*, is no more than an Augmentation and Expanſion of the minute Parts of the Body of the Seed: So that the whole Species which are afterwards produced, were in Reality all form'd at the firſt, and incloſ'd therein, to be brought forth and excloſ'd to View in Time, and according to a certain Order and Oeconomy.

And accordingly Dr. *Garden* ſays, It is moſt probable that the *Stamina* of all the Plants and Animals that have been, or ever ſhall be in the World, have been form'd, *ab Origine Mundi*, by the Almighty Creator, within the firſt of each reſpective Kind: And he who conſiders the Nature of Viſion, that it does not give us the true Magnitude, but only the Proportion of Things, and that which ſeems to our naked Eye but a Point, may truly be made up by as many Parts as ſeem to be in the whole Univerſe, will not think this an abſurd or impoſſible Thing.

Dr. *Blair*, treating of the *Generation* of *Plants*, ſays, That when Almighty God created the World, he ſo order'd and diſpos'd of the *Materies Mundi*, that every Thing produced from it ſhould continue ſo long as the World ſhould ſtand. Not that the ſame individual Species ſhould always remain; for they were, in Proceſs of Time, to periſh, decay, and return to the Earth from whence they came. But that *every Like ſhould produce its Like*, every Species ſhould produce its own Kind, to prevent a final Deſtruction of the Species, or the Neceſſity of a new Creation, in order to continue the ſame Species upon Earth, or in the World.

For which End he laid down certain Regulations, by which each Species was to be propagated, preſerved, and ſupported, 'till in Order or Courſe of Time, they were to be remov'd hence; for, without that, thoſe very Beings which were created at firſt, muſt have continued to the final Diſſolution of all Things; which Almighty God, of his infinite Wiſdom, did not think fit.

But that he might ſtill the more manifeſt his Omnipotence, he ſet all the Engines of his Providence to work, by which one Effect was to produce another by the Means of certain Laws or Rules laid down for the Propagation, Maintenance, and Support of all created Beings: This his divine Providence is call'd *Nature*, and theſe Regulations are call'd the *Laws* or *Rules* of *Nature*, by which it ever operates in its ordinary Courſe; and whatever recedes from that, is ſaid to be preternatural, miraculous, or monſtrous.

Moſes, in his Account of the *Creation*, tells us, that Plants have their Seeds in themſelves, in theſe Words; *And God ſaid, Let the Earth bring forth Graſs, the Herb yielding Seed, and the Fruit-tree yielding Fruit, after his Kind, whoſe Seed is in itſelf upon the Earth.*

The Antients, indeed, diſtinguiſh'd the *Generation of Animals* into two Kinds; *i. e.* into *Regular*, call'd *Univocal*; and *Anomalous*, call'd alſo *Equivocal*, or *Spontaneous*.

The firſt was effected by Parent Animals of the ſame Kind; as that of Men, Birds, Beaſts, *&c.* The ſecond they ſuppos'd to be effected by Corruption, the Sun, *&c.* as that of Inſects, Frogs, *&c.* But this latter is now generally exploded.

Many, indeed, have eſſay'd to treat of the *Generation of Animals*; but few have been able to give that ſatisfactory Account of it that were to be wiſh'd for, and far fewer yet have been able to treat of the *Generation of Plants* ſo as it ought to be; for that which ſtill kept them in the Dark, was,

1ſt: That tho' there were two different Sexes in Animals, by whoſe mutual Aſſiſtance the Species was propagated, yet there was no ſuch Thing then known in Plants.

2dly: That tho' it can now be made appear, that every Animal is produced by *Univocal Generation*, i. e. from an *Egg*, and not by Corruption, *&c.* as moſt of the Antients imagin'd the Inſects were; yet there are ſtill thoſe who maintain, that thoſe which they call *Imperfect Plants*, are the Product of a certain Rottenneſs in the Earth.

The *Generation of Plants* bears a cloſe Analogy to that of ſome *Animals*, eſpecially ſuch as want local Motion, as Muſcles, and other immoveable Shell-fiſh, which are Hermaphrodites, and contain both the Male and Female Organs of *Generation*.

The Flower of a Plant, is found to be the *Pudendum*, or principal Organ of *Generation*; but the Uſe of ſo much Mechaniſm, and ſo many Parts, has been but little known.

The Flower of a *Lily* conſiſts of ſix *Petala*, or Flower Leaves; from the Bottom of which, at the Middle, ariſes a Kind of Tube, call'd the *Piſtillum*; and pretty fine Threads, call'd the *Stamina*, are diſpos'd around it: Theſe *Stamina* are likewiſe from the Bottom of the Flower, and terminate at the Top in little Bunches call'd *Apices*, which are replete with a fine Duſt call'd *Farina*.
